PRESENTACIÓN

Como lo marca la Legislación Universitaria presento ante las autoridades, a las y los miembros de nuestro Instituto y a la Comunidad Universitaria el Informe de Labores del Instituto de Fisiología Celular correspondiente al año 2019.

En este año el Instituto mantuvo su compromiso con la labor docente de alta calidad impulsando un enfoque moderno de la ciencia y de los temas de investigación que se cultivan en nuestra entidad. Particular atención fue puesta en la transmisión del conocimiento por parte de jóvenes investigadores, apoyándonos en la experiencia de las y los investigadores consagrados, todos ellos líderes en su campo de investigación, en la impartición de cursos de licenciatura y posgrado.

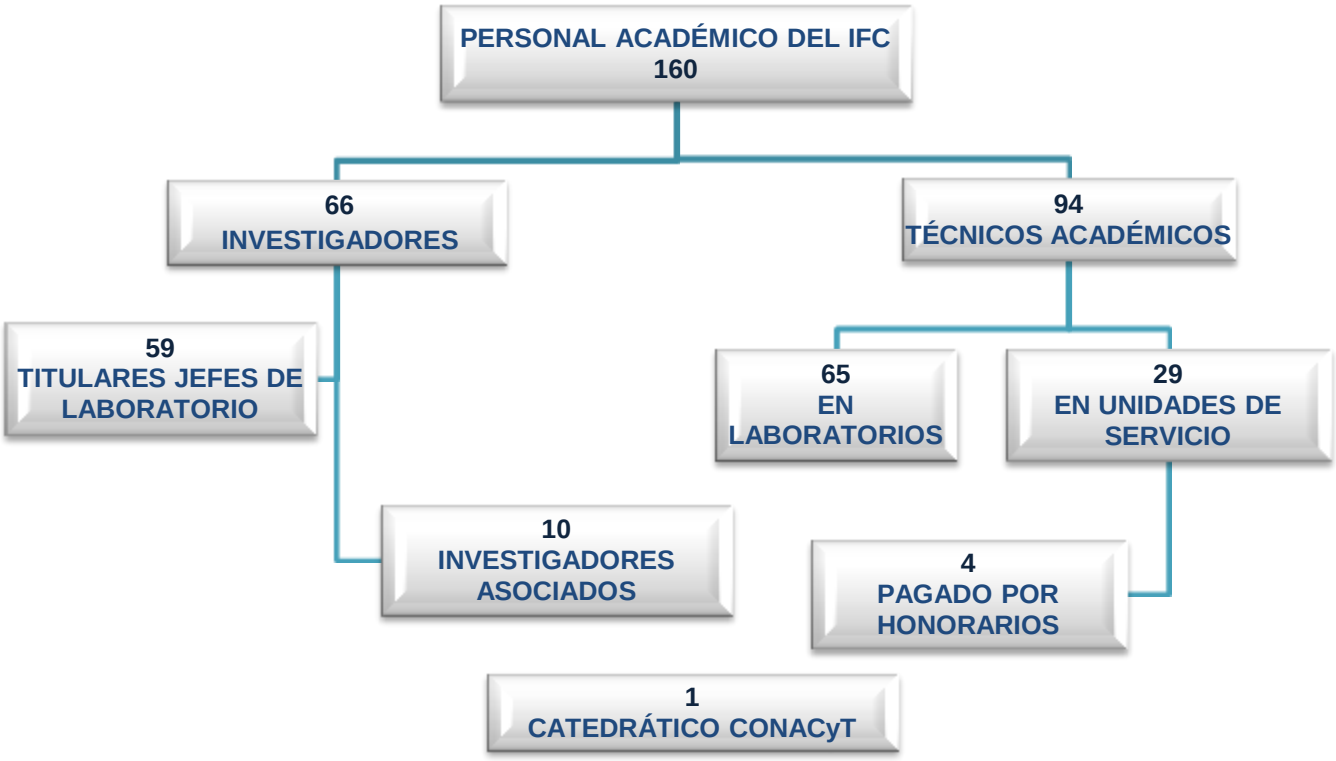
Un total de 508 estudiantes asistieron a nuestras aulas y laboratorios. De los cuales 75 obtuvieron el grado: 14 de Licenciatura, 36 de Maestría y 25 de Doctorado. Afianzamos nuestra relación y participación en los posgrados de Ciencias Bioquímicas, Ciencias Biomédicas y Ciencias Biológicas. Como entidad responsable, junto con la Facultad de Medicina, tuvimos una activa participación en la Licenciatura de Neurociencias organizando e impartiendo un gran número de cursos. Además, renovamos nuestra participación en la Licenciatura en Investigación Biomédica Básica.

En el ámbito de la investigación científica publicamos 117 artículos en revistas indizadas lo que representa 2.05 artículos por grupo de investigación, con un índice de impacto promedio de 5.02. En el 2019 el 71% de nuestras publicaciones se encuentran el Cuartil 1 (Q1), 21% en el Cuartil 2 (Q2) lo cual implica que el 92% de nuestras publicaciones se encuentran en los cuartiles Q1+Q2. Por otra parte, en el mismo periodo se publicaron 6 capítulos (8 en prensa), 9 artículos de divulgación, 2 libros y 6 artículos en revistas nacionales. El análisis de nuestra productividad muestra que en este año publicamos 25 artículos menos en comparación con el 2018, sin embargo, el factor de impacto promedio pasó de 4.263 a 5.02 en el 2019. Considero que la disminución en el número de artículos refleja el momento de cambio generacional que vive nuestro Instituto, sin que esta disminución sea en detrimento de la calidad de nuestras investigaciones al incrementar en casi un punto el factor de impacto promedio de nuestras publicaciones.

Como una consecuencia de nuestro compromiso por realizar investigaciones del más alto nivel, los miembros de nuestra comunidad recibieron diversos premios y reconocimientos. Se destacan la medalla *Sor Juana Inés de la Cruz* otorgada a la Dra. Teresa Montiel Montes, el Dr. Ranulfo Romo fue reconocido con el Premio Crónica de Ciencia y Tecnología, el Dr. Jaime Mas Oliva fue galardonado con el *Premio Universidad Nacional 2019* en el área de Investigación en Ciencias Naturales, el Dr. Fatuel Tecuapetla Aguilar obtuvo la *Cátedra Marcos Moshinsky 2019*, y la Dra. Claudia Álvarez Carreño y el Dr. Luis Vaca Domínguez fueron acreedores a la beca *Fullbright-García Robles* para realizar estancias de Investigación en Estados Unidos.

En este año se mantuvo la distribución por género del personal del Instituto. De este análisis se desprenden datos interesantes que muestran que en la población académica del Instituto 40% de los investigadores son mujeres y 60% hombres. En cuanto a los Técnicos Académicos la relación es de 2 a 1 en favor de las mujeres. Cabe resaltar que la relación en Investigadores Titular A y B entre mujeres y hombres es prácticamente de 1:1, mientras que el 70% de los Investigadores Titulares C son hombres, mostrando una tendencia histórica. Sin embargo, en las nuevas generaciones la equidad de género se va asentando en nuestro Instituto. En cuanto al personal de base y de confianza, el Instituto está compuesto mayoritariamente por mujeres y la relación es 1:1 en cuanto al personal administrativo. A todo lo anterior se suma un esfuerzo por realizar actividades coordinadas a través del trabajo comprometido de la Comisión Interna de Igualdad de Género.

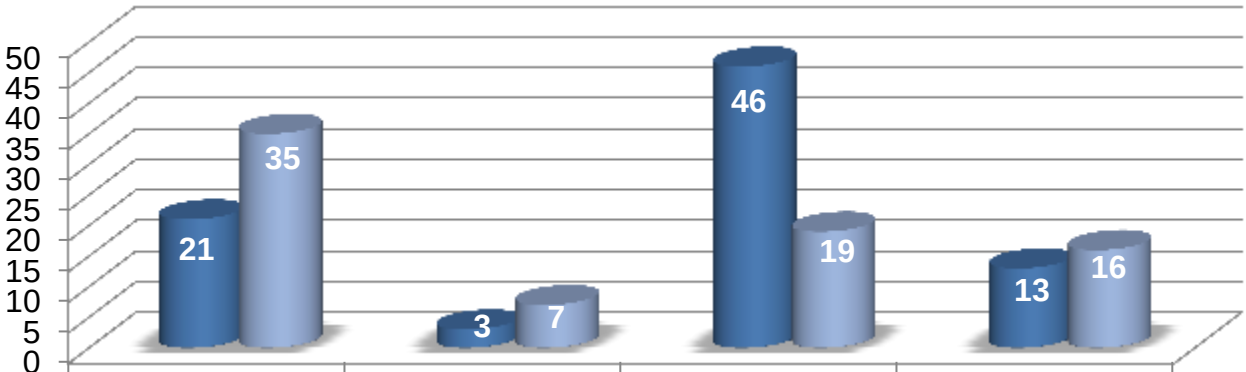
Un hecho que deseo destacar es la creación y puesta en funcionamiento de dos nuevas Unidades de Servicio en nuestro Instituto. Se construyó y equipó la Unidad de Edición Genética (CRISPR-Cas) y Criopreservación. Se equipó el edificio anexo para albergar a la Unidad de Bioinformática y Manejo de la Información. Además, un hecho fundamental para el funcionamiento de nuestro Instituto fue la puesta en marcha de la nueva Red de Cómputo. En el 2019 el edificio anexo entró en funcionamiento albergando al Laboratorio Nacional de Canalopatías, y además se construyeron dos aulas y la Unidad para albergar a los ratopines, un modelo único en México para estudios de envejecimiento. Finalmente, el Instituto y sus investigadores obtuvieron un apoyo para Infraestructura por parte del CONACyT de más de 25 millones de pesos para el Fortalecimiento de las Unidades de Bioterio, y de Edición Genética y Criopreservación, así como equipo para estudios de célula única. Además de una serie de adecuaciones y mantenimiento de la infraestructura del Instituto.



Finalmente, agradezco el apoyo brindado por parte del Sr. Rector, el Dr. Enrique Graue Wiechers, el Coordinador de la Investigación Científica, el Dr. William Lee Alardín y el Secretario Administrativo de la UNAM, el Ing. Leopoldo Silva Gutiérrez.

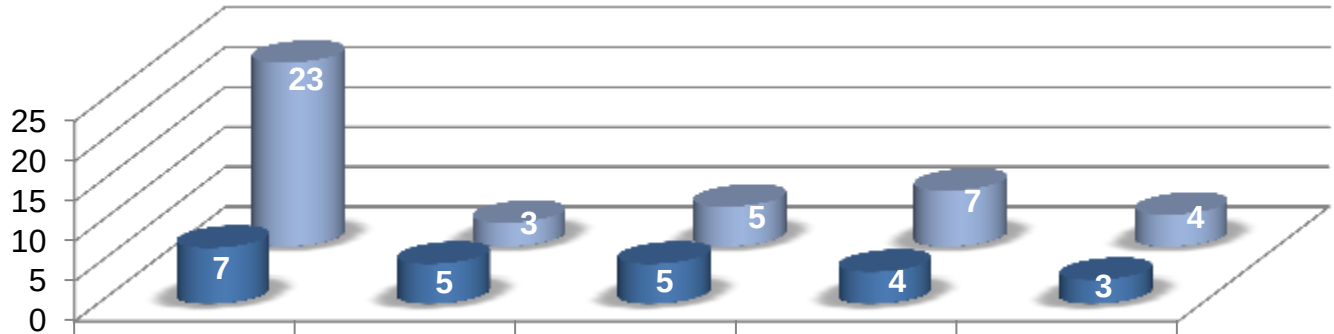
Solo me queda reiterar mi agradecimiento a las autoridades por su apoyo constante, consejos y atenciones hacia nuestro Instituto, a la comunidad estudiantil y a las y los miembros del Instituto de Fisiología Celular de la UNAM.

Dr. Félix Recillas Targa
Director



PERSONAL ACADÉMICO

En el 2019 la plantilla académica del Instituto de Fisiología Celular cuenta con 160 miembros, 66 son Investigadores, 94 son Técnicos Académicos y uno es Catedrático CONACyT. Del total de Investigadores, 59 son Jefes de Grupo y 10 son Investigadores Asociados. Los Técnicos Académicos adscritos a algún laboratorio son 65 y 29 se encuentran en las Unidades de Servicio del Instituto, cuatro de ellos están contratados por honorarios.



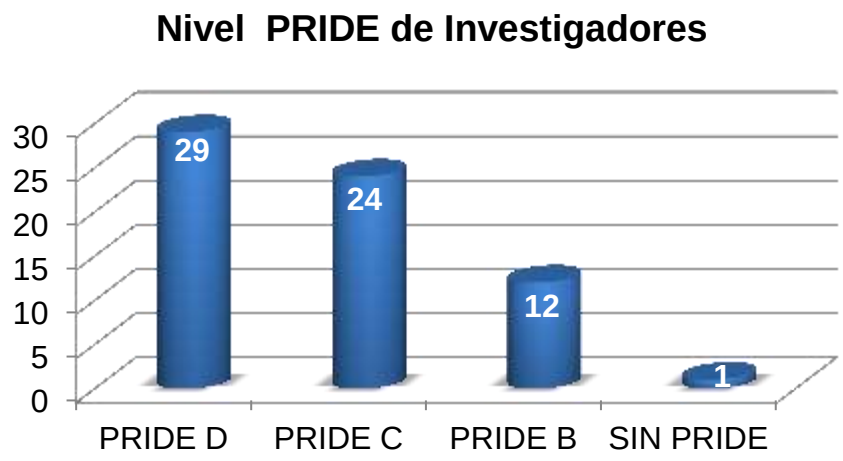
La distribución de equidad de género entre el Personal Académico se muestra en la siguiente gráfica.

Distribución del Personal Académico por Género

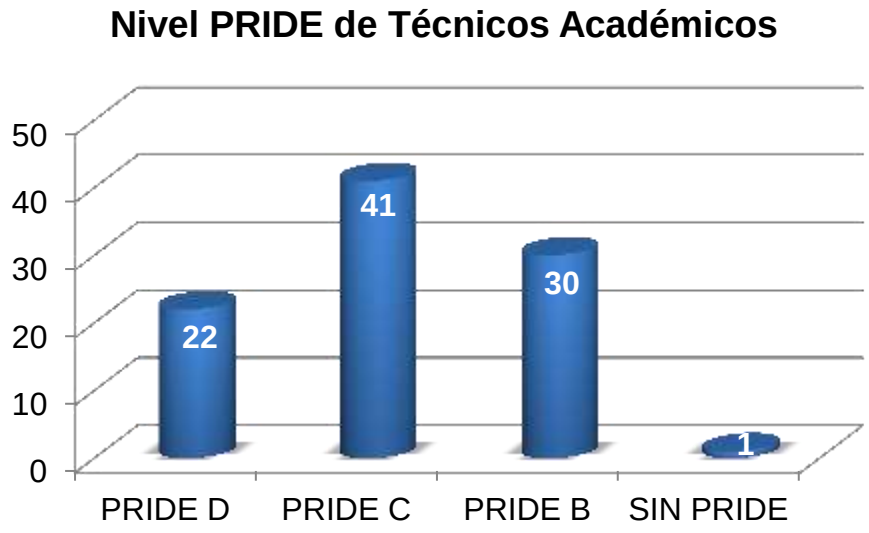
	INV. TITULARES	INV. ASOCIADOS	TEC. EN LABORATORIO	TEC. EN UNIDADES ACADEMICAS
MUJER	21	3	46	13
HOMBRE	35	7	19	16

Distribución de Investigadores por Género

	INV TIT "C"	INV TIT "B"	INV TIT "A"	INV ASO "C"	INV EMÉRITO
Mujeres	7	5	5	4	3
Hombres	23	3	5	7	4

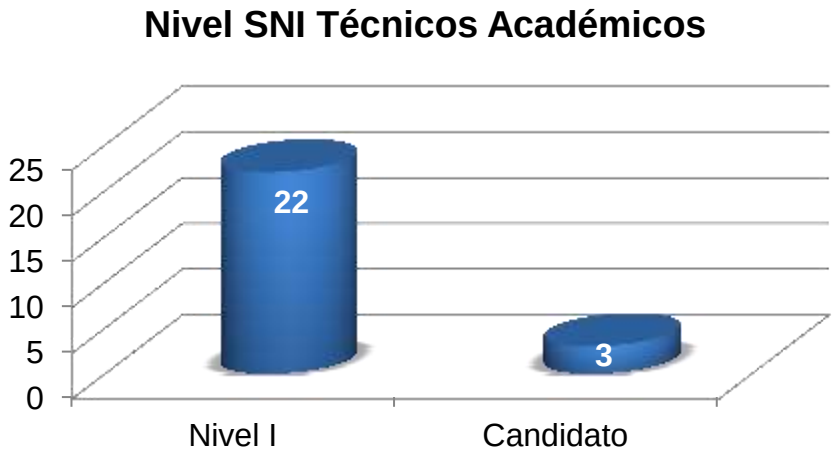


En 2019, el IFC cuenta con 7 Investigadores Eméritos, el nombramiento con mayor número de integrantes fue Titular C con 30 miembros que representan el 46% del total, 8 investigadores son Titular B, 10 tienen el nombramiento Titular A y 10 Asociado C.



En el mismo periodo, 27 Técnicos Académicos tuvieron nombramiento de Titular C, Titular B y Titular A. 12 son Asociado C, 1 tiene el nombramiento de Asociado A y 4 tienen un contrato por honorarios.

En lo que respecta al programa de Primas al Desempeño del Personal Académico (PRIDE) en el caso de los investigadores predomina el Nivel D, ya que 29 de ellos tienen el nivel, le siguen 24 investigadores en el Nivel C, 12 tienen el nivel B del PRIDE o equivalente y solo un investigador perdió dicho estímulo.



En el caso de los Técnicos Académicos, 41 tiene Nivel C del PRIDE, 30 tiene Nivel B o equivalente, 22 Técnicos Académicos han logrado el Nivel D y 1 no tiene el estimulo.

En el Sistema Nacional de Investigadores (SNI), 7 Investigadores han sido reconocidos con el máximo nivel, es decir, como Eméritos, 21 Investigadores poseen el nivel III, 14 tienen el nivel II, el nivel I lo obtuvieron 21 Investigadores y 1 es Candidato.

Son 22 Técnicos Académicos que se encuentran en el nivel I del SNI y 3 son candidatos.

***Guerra Crespo Magdalena, Dra.**	**Investigador Titular A. PRIDE C. SNI nivel I.**

*Académica que depende del Jefe de Departamento.

LÍNEAS DE INVESTIGACIÓN

BIOLOGÍA CELULAR Y DEL DESARROLLO

Aguirre Linares Jesús

- Diferenciación celular y regulación genética en microorganismos eucariotas: transducción de señales, respuestas al estrés oxidativo y regulación del metabolismo secundario en los hongos.

Chagoya de Sánchez Victoria

- Caracterización y función del ciclo circádico de la adenosina.
- Hepatoxicidad aguda y crónica con etanol, tetracloruro de carbono y dietilnitrosamina, cirrosis, cáncer hepatocelular y síndrome metabólico.
- Cardiotoxicidad durante el infarto de miocardio experimental y la insuficiencia cardiaca.

García Sáinz Jesús Adolfo

- Receptores acoplados a proteínas G.

Hansberg Torres Wilhelm

- Diferenciación celular en microorganismos.
- Especies reactivas del oxígeno.
- Relación estructura función de las catalasas.

Hernández Muñoz Rolando

- Regulación del metabolismo intermedio durante la proliferación celular *in vivo*.
- Identificación de moléculas involucradas en la comunicación inter-órganos y su repercusión en el metabolismo general.
- Mecanismos de producción y potencial reversión de la cirrosis experimental.
- Caracterización del metabolismo nitrogenado en eritrocitos humanos y de las enzimas involucradas en dichas vías.

Licona Limón Paula

- Papel del factor de crecimiento transformante beta (TGF-β) y de la vía de PKA en la diferenciación de subtipos celulares de linfocitos T.
- Caracterización de los mecanismos efectores de defensa y las vías de señalización que controlan la respuesta inmune contra parásitos.
- Estudio de los mecanismos de co-evolución parasito-hospedero.

- Estudio de la respuesta inmune a cepas bacterianas multidrogoresistentes para el diseño de inmunoterapias.
- Estudio del papel de IL-9 en contextos de infección parasitaria, alergias y autoinmunidad.
- Identificación de marcadores moleculares asociados a poblaciones linfoides productoras de IL-9.

López Casillas Fernando

- Mecanismos moleculares de acción y señalamiento de factores autócrinos y parácrinos de crecimiento celular, en particular del TGF-β (*Transforming Growth Factor type beta*).
- Caracterización estructura-función del betaglicano, también llamado el receptor tipo III del TGF-β.
- Participación del betaglicano en el desarrollo embrionario del pez cebra.

Macías Silva Marina

- Vías de transducción de señales de la citocina TGF-β.
- Regulación de la expresión de genes.
- Modificaciones Postraduccionales.
- Plasticidad celular.

Navarro González Rosa

- Regulación de la formación de gránulos de RNA en la gónada del nematodo *Caenorhabditis elegans*.
- Mecanismos de inducción de apoptosis de las células germinales del *Caenorhabditis elegans*.

Vaca Domínguez Luis

- Canales TRP.
- Entrada de calcio capacitiva.
- Desarrollo de sensores nanomoleculares para investigación y diagnostico.

Valdés Víctor Julián

- Neuroepigenética de la conducta en modelos de aprendizaje y memoria.
- Estudio de cambios epigenéticos y transcripcionales inducidos por alta glucosa.

BIOQUÍMICA Y BIOLOGÍA ESTRUCTURAL

Arciniega Castro Marcelino

- Desarrollo de algoritmos bayesianos para búsqueda de inhibidores a gran escala.
- Estimaciones de cambios en energía libre asociados con cambios conformacionales en proteínas.
- Estudios de alostería emplando simulaciones de dinámica molecular y teoría de redes.

Del Río Guerra Gabriel

- Estudio de la relación estructura-función en sistemas biológicos mediante el análisis de redes.
- Diseño asistido por computadora de péptidos capaces de inducir muerte celular selectiva.

González Manjarrez Alicia

- Duplicación génica y evolución en la levadura *Saccharomyces cerevisiae*.
- Diversificación funcional de genes parálogos: Papel de la localización subcelular, regulación transcripcional y propiedades bioquímicas de los productos codificados.
- Caracterización de genes tipo ancestral en *Kluyveromyces lactis* y *Lacchancea kluyveri*.
- Organización de proteínas paralogas hetero-oligomericas: Una instancia de diversificación funcional.
- Papel de Leu3 en la determinación del "lifespan" de la levadura *Saccharomyces cerevisiae*.
- Estudio de la organización y papel regulatorio de los complejos transcripcionales híbridos.

Mas Oliva Jaime

- Membranas biológicas y su función.
- Correlación estructura/función en proteínas.

Molinari Soriano José Luis

- Cisticercosis experimental.

Peraza Reyes Leonardo

- La regulación de la biogénesis peroxisomal durante el desarrollo sexual de *Podospora anserina*.
- La función de los peroxisomas durante el desarrollo meiótico de *Podospora anserina*.

- La dinámica y las interacciones de las mitocondrias, los peroxisomas y el retículo endoplásmico durante el desarrollo de los hongos.
- La dinámica y función del retículo endoplásmico durante el desarrollo sexual de *Podospora anserina*.
- La dinámica y las interacciones de los endosomas y los peroxisomas durante el desarrollo de los hongos.

Pérez Montfort Ruy

- Identificación de amino ácidos importantes para diferentes propiedades bioquímicas en triosafosfato isomerasas de tripanosomas.
- Inactivación selectiva de triosafosfato isomerasas de tripanosomátidos.

Torres Larios Alfredo

- Cristalografía de macromoléculas.
- Interacciones macromolécula-ligando.

Torres Quiroz Francisco

- Producción de ácido sulfhídrico en levadura y la regulación de procesos celulares.
- Regulación del proteosoma por modificaciones postraduccionales.
- Efecto del ácido sulfhídrico en un modelo de isquemia cerebral transitoria.
- Papel de la persulfuración de proteínas en la producción de leche en rumiantes.

Tuena de Gómez Marietta

- Regulación de la actividad de la ATPasa mitocondrial y de su estado oligomérico.
- Estudio sobre Triosafosfato isomerasa, regulación de la síntesis.
- Evolución de triosafosfato isomerasa.
- Estudio de la remodelación cardiaca subsecuente al infarto del miocardio inducido por isoproterenol y el efecto de un derivado de adenosina.

GENÉTICA MOLECULAR

Álvarez Adrián Fernando

- Estudio intergral de microdominios membranales bacterianos.
- Estudio del sistema de dos componentes ArcB/ArcA de *Escherichia coli*.
- Estudio del sistema de dos componentes BarA/UvrY y su relación con el sistema de regulación global Csr.

Celis Sandoval Heliodoro

- Estructura, función y regulación de las pirofosfatasas de bacterias fotosintéticas.
- Caracterización de los centros de reacción de bacterias fotosintéticas.

Coria Ortega Roberto

- Sistemas de transducción en levaduras y *Dictyostelium*. Mecanismos moleculares de la respuesta a estrés de retículo endoplásmico en levaduras y en *Dictyostelium*.

Dreyfus Cortés Georges

- Motilidad en bacterias.

Funes Argüello Soledad

- Respuestas mitocondriales ante condiciones de estrés y durante la regulación de la longevidad celular en *Saccharomyces cerevisiae.*
- Mecanismos de importación co-traduccional de proteínas a la mitocondria.

Furlan Magaril Mayra

- Relación entre la estructura 3D del genoma y la regulación de la actividad transcripcional.
- Topología genómica, accesibilidad cromatínica y modulación transcripcional durante la maduración y diferenciación eritroide.
- Topología genómica y regulación transcripcional de genes circadianos.
- Caracterización molecular y funcional de fronteras entre dominios topológicamente asociados.

Georgellis Dimitris

- Control of microbial gene expression by extra-cellular stimuli.
- Structure and function of proteins involved in bacterial signal transduction.

- Bacterial plasma membrane microdomains: Control of two-component system signaling and beyond.
- Characterization of the BarA/UvrY and ArcB/ArcA two component signal transduction systems of *Escherichia coli*.

González Halphen Diego

- Caracterización bioquímica y de genética molecular de los componentes de la fosforilación oxidativa del alga clorofícea incolora *Polytomella sp*.
- Relaciones estructura-función de los complejos mitocondriales.
- Expresión alotópica de genes mitocondriales.
- Caracterización de la maquinaria importadora de proteínas de los amiloplastos del alga incolora *Polytomella sp*.

González Pedrajo Bertha

- Sistema de secreción tipo III en bacterias Gram negativas.
- Mecanismos moleculares de la secreción de efectores de virulencia en *Escherichia coli* enteropatógena.
- Patogénesis bacteriana.
- Desarrollo de terapias para tratar infecciones bacterianas.

Peña Díaz Antonio

- Transporte y homeostasis de iones en distintas levaduras, así como su relación con el metabolismo energético, en particular ante condiciones extremas de salinidad y pH.
- Efectos de diferentes antimicóticos en levaduras patógenas.
- Mecanismos de adaptación de la levadura *Debaryomyces hansenii* a las condiciones del agua marina o de mayor salinidad y valores elevados del pH; cambios del metabolismo y de la expresión genética.
- Transporte y metabolismo de la xilosa en levaduras no convencionales.
- Mecanismos del transporte de calcio en *Candida albicans*.
- Caracterización estructural, cinética y fisiológica de las NADH deshidrogenasas externas de *Saccharomyces cerevisiae*.

Pérez Martínez Xóchitl

- Mecanismos de biogénesis del citocromo b mitocondrial.
- Mecanismos de control traduccional y de ensamblaje de Cox1 en mitocondrias de *Saccharomyces cerevisiae*.
- Estudio del papel de la compleja regulación de la síntesis de Cox1 en la fisiología de células de *Saccharomyces cerevisiae*.
- Estudio de los mecanismos de acoplamiento entre la traducción citosólica y la mitocondrial.

Recillas Targa Félix

- Estructura de la cromatina y actividad reguladora de la región 3’ no-codificante del dominio α-globina de pollo.
- Caracterización y estudio de los mecanismos de la formación de un dominio transcripcionalmente activo.
- Regulación epigenética de la expresión de genes supresores de tumores y secuencias repetidas.
- Regulación epigenética mediada por RNAs largos no-codificantes.
- Estudio de la organización tri-dimensional del genoma en la regulación de la expresión génica.

Uribe Carvajal Salvador

- Bioenergética de levaduras.
- Coordinación del catabolismo en *Saccharomyces cerevisiae*.
- Bioquímica de *Wolbachia sp*.

NEUROCIENCIA COGNITIVA

Aguilar Roblero Raúl

- Regulación neuroendócrina de los ritmos circadianos en mamíferos.

Bargas Díaz José

- Modulación presináptica de la transmisión entre neuronas.
- Estudio del funcionamiento de los microcircuitos cerebrales.
- Arquitectura funcional de la corteza motora del ratón.

Bermúdez Rattoni Federico

- Mecanismos moleculares y estructurales en la formación y evocación de la memoria de reconocimiento.
- Detección de señales moleculares tempranas que subyacen a los trastornos cognitivos en ratones transgénicos con enfermedad de Alzheimer.

Fernández De Miguel Francisco

- Secreción de serotonina somática y sináptica.
- Enseñanza experimental de las ciencias.
- Arte y cerebro.
- Determinantes moleculares de las sensaciones de tacto y dolor.

Galarraga Palacio Elvira

- Comparación de las oscilaciones en el potencial de membrana en neuronas corticales y en neuronas intralaminares del tálamo.
- Control del mecanismo de disparo neuronal y su neuromodulación: acciones directas e indirectas.
- Integración Sináptica de diferentes tipos neuronales en respuesta a aferentes de distinto origen: talámicas y corticales.

Hernández Cruz Arturo

- Homeostasis del calcio intracelular en neuronas y células endocrinas.
- Participación de las células cromafines de la glándula suprarrenal en la fisiopatología de la hipertensión.
- Estudio de la señalización por calcio intracelular en células foliculares durante el ciclo estral en rebanadas de ovario de ratón.
- Papel de canales iónicos selectivos al potasio implicados en la biología de distintos tipos de cáncer.

- Papel de los transportadores aniónicos en la regulación por GABA de la función de las células cromafines de la médula adrenal.
- El papel del GABA endógeno actuando sobre receptores GABAA en las fluctuaciones espontáneas de [$Ca2^{+}$]i, la transmisión colinérgica y la secreción de catecolaminas de las células cromafines adrenales *in situ*.
- La encefalitis asociada a la presencia de anticuerpos contra el receptor de N-metil-D-aspartato (NMDA-R): Una canalopatía inducida con pérdida de función.
- Estudios de señalización por calcio intracelular en centenares de células únicas empleando agonistas específicos y dispositivos de microfluídica (Colaboración con el grupo del Dr. José Luis García Cordero. CINVESTAV-Monterrey).
- Estudios funcionales de cardiomiocitos humanos diferenciados de células pluripotentes inducidas de sujetos normales y pacientes con síndrome de Andersen-Tawil, una cardio-canalopatía del canal de potasio Kir2.1 que cursa con arritmia y muerte súbita.

Hiriart Urdanivia Marcia

- Modulación del acoplamiento entre el estímulo y la secreción hormonal de células beta pancreáticas sanas y en condiciones diabéticas.
- Regulación del desarrollo, la plasticidad y el funcionamiento de las células beta pancreáticas.
- Mecanismos fisiopatológicos de desarrollo de la resistencia a la insulina, obesidad, síndrome metabólico y diabetes.
- Efecto de tóxicos sobre la secreción de insulina y desarrollo de las células beta.

Lemus Sandoval Luis

- Representación cortical de objetos auditivos.
- Representación de estímulos amodales.

Morales Lázaro Sara Luz

- Regulación de la expresión de canales TRPs asociados a la generación de dolor.
- Regulación del canal TRPV1 por endocanabinoides.
- Regulación del canal TRPV1 por efecto de moléculas esteroideas.

Osorio Gómez Daniel

- Efecto de la obesidad en los mecanismos celulares y moleculares del aprendizaje y la memoria.
- Evaluación por optogenética de la participación de la proyección amígdala-corteza insular en el establecimiento de la valencia de los estímulos.

Pérez de la Mora Miguel

- Interacciones de neurotransmisores dentro de la amígdala de la rata y su relevancia en la modulación de la ansiedad.
- Diabetes y ansiedad.
- Papel de los sistemas oxitocinérgicos y vasopresinérgicos en la modulación amigdalina de la ansiedad.
- Papel de la neurotrasmisión dopaminérgica en la modulación amigdalina de la ansiedad.
- Papel de los sistemas de neurotransmisión catecolaminérgicos en el mecanismo de la acción ansiolítica y prosocial de la 3’4’ Metilen-dioxi-metanfetamina (éxtasis).
- Alteraciones neurocognitivas en la adolescencia temprana por el consumo de inhalantes.
- Sobre-expresión específica del gene de la triptofano 5 hidroxilasa (TPH2) en neuronas serotoninérgicas y evaluación de la producción de serotonina.

Romo Trujillo Ranulfo

- Neurobiología de la percepción.

Rosenbaum Emir Tamara

- Relaciones entre la estructura y la función de los canales de tipo TRPV1.
- Estudios sobre la regulación de la actividad de canales TRP por hormonas y lípidos.

Rossi Pool Román

- Neurociencia computacional.
- Análisis estadístico de mediciones electrofisiológicas.
- Modelado de sistemas dinámicos y redes neuronales.
- Mediciones electrofisiológicas en primates entrenados.
- Decodificación de actividad de neuronas individuales y poblaciones.

Velasco Torres Myrian

- Modulación de la secreción de insulina por canales de potasio.
- Actividad de canales iónicos en el síndrome metabólico.

NEURODESARROLLO Y FISIOLOGÍA

Castro Obregón Susana

- Papel de la autofagia durante el desarrollo y envejecimiento del sistema nervioso, así como en la estabilidad del genoma.

Escalante Alcalde Diana

- Papel de la fosfatasa de fosfolípidos-3 (PLPP3, antes LPP3) en el desarrollo y en enfermedades.

López Huerta Violeta Gisselle

- Patrones de conectividad en circuitos talámicos control y en modelos de autismo.
- Control inhibitorio de circuitos talámicos en el adulto y durante el desarrollo.

Pasantes Ordóñez Herminia

- Mecanismos moleculares del edema cerebral.
- Taurina y células progenitoras neuronales y transdiferenciación neuronal.

Ramiro Cortés Yazmín

- Plasticidad sináptica y sus correlatos estructurales en el autismo en hipocampo y corteza visual.
- Actividad neuronal de corteza visual primaria *in vivo* en ratones despiertos en el autismo.

Salceda Sacanelles Rocío

- Neurotransmisión glicinérgica en la retina de los vertebrados.
- Relación funcional entre el epitelio pigmentario de la retina y la retina neural.
- Retinopatía diabética.
- Neuropatía diabética.

Velasco Velázquez Iván

- Biología de células troncales neurales en el desarrollo del cerebro.
- Uso de las células troncales embrionarias en el tratamiento de enfermedades del sistema nervioso.
- Reprogramación de células somáticas a estado pluripotencial.
- Regeneración del sisema nervioso del ajolote.

NEUROPATOLOGÍA MOLECULAR

Gómora Martínez Juan Carlos

- Relación estructura-función de canales de calcio activados por voltaje.
- Participación de los canales de sodio en las propiedades metastásicas del cáncer cervicouterino.

Guerra Crespo Magdalena

- Estudio de la diferenciación de células pluripotentes inducidas humanas *in vitro* e *in vivo* en patologías cardiacas.
- Estudio del potencial neuronal y dopaminérgico de células troncales embrionarias y células pluripotentes inducidas humanas *in vitro* e *in vivo* en el contexto de la enfermedad de Parkinson

López Colomé Ana María

- Neurotransmisión excitadora en la retina: mecanismos y regulación.
- El glutamato y la trombina como agentes causales de patologías que producen ceguera.

Massieu Trigo Lourdes

- Mecanismos de muerte neuronal asociados a la isquemia/hipoglucemia.
- Respuestas al estrés energético en neuronas. Estrés oxidante, estrés del retículo endoplásmico y autofagia.

Morán Andrade Julio

- Mecanismos moleculares de la muerte neuronal programada.
- Papel de las especies reactivas del oxígeno en la muerte y diferenciación neuronal.
- Papel de la NADPH-oxidasa en la muerte y diferenciación neuronal.

Olguin Albuerne Mauricio

- Crecimiento axonal y dendrítico.
- Migración neuronal.

Sotres Bayón Francisco

- Neurobiología de la supresión activa del miedo en busca de una recompensa.
- Neurobiología de conductas de elección guiadas por motivaciones gustativas.
- Neurobiología de la expresión e inhibición pasiva del miedo condicionado.

Tapia Ibarguengoytia Ricardo

- Modelos experimentales de epilepsia y enfermedades neurodegenerativas.
- Mecanismos de muerte neuronal.
- Bioética y neuroética.

Tecuapetla Aguilar Fatuel

- Subcircuitos de la corteza-ganglios basales-tálamo en condiciones normales y neuropatológicas.

Tovar y Romo Luis Bernardo

- Regulación trófica de la viabilidad neuronal; mecanismos endógenos de recuperación después del infarto cerebral isquémico.
- Estudio de las respuestas moleculares de los astrocitos en la isquemia cerebral.
- Regulación epigenómica y transcriptómica del infarto cerebral isquémico.
- Mecanismos de recuperación neuronal mediados por interacciones con el endotelio vascular.

ACTIVIDADES ACADÉMICO ADMINISTRATIVAS

Aguilar Roblero Raúl

- Revisor Externo del PAPIIT.
- Revisor Externo del CONACyT.
- Revisor externo de Biomedical Physics & Engineering Express.
- Revisor Externo Frontiers in Integrative Neuroscience.

Aguirre Linares Jesús

- Revisor de proyectos para CONACyT, PAPIIT,y de artículos para las revistas PLoS One, Frontiers in Microbiology, Scientific Reports, Fungal Biology and Applied and Environmental Microbiology.
- Miembro de la comisión dictaminadora externa del CICESE desde el 2013 (duración indeterminada).
- Miembro del Comité Evaluador del PAPIIT-UNAM.

Arciniega Castro Marcelino

- Participación en la comisión de cómputo del IFC-UNAM.
- Participación como evaluador en el proceso de selección de candidatos a cursar estudios de posgrado en el extranjero en el marco de la convocatoria CONACyT-Regional Sur-Oriente y Noroeste.
- Participación como evaluador de proyectos PAPIIT.

Bargas Díaz José

- Comisión Evaluadora del PRIDE. Instituto de Fisiología Celular, UNAM.
- Comisión Evaluadora PRIDE Instituto de Ecología, UNAM.
- Revisor de Artículos de Investigación para su publicación en Revistas Internacionales y Nacionales: Brain Research, Trends in Neuroscience, Journal of Neuroscience, Journal of Neurophysiology, Synapse, BMC-Neuroscience, Neuroscience, Journal of Pharmacy and Pharmacology, Proceedings of the Nacional Academy of Sciences, European Journal of Neuroscience, Journal of Neuroscience Research, Revista de Neurología, Neuropsychopharmacology, Experimental Neurology, Frontiers in Cellular Neuroscience, Frontiers in Systems Neuroscience, Journal of Physiology (London), PLoS Computational Biology, Neurocomputing, Biological Psychiatry, Movement Disorders, Neurochemical Research, Learning and Memory, Nature, Scientific Reports, Neurobiology of Disease,

Neuroscience Letters, Revista Biomédica, Frontiers in Neuroanatomy, Revista Mexicana de Ingeniería Biomédica, Basal Ganglia, Journal of Applied Research and Technology, e-Life.

- Revisión de Proyectos de Investigación para dictaminar su apoyo: Proyectos de PAPIIT-UNAM.
- Revisión de Proyectos de Investigación para dictaminar su apoyo: Proyectos de CONACyT.
- Proyectos Internacionales: Netherlands, Colombia, Argentina, New Zealand.
- Miembro y actual presidente de la Internacional Basal Ganglia Society (IBAGS).

Bermúdez Rattoni Federico

- Comisión Evaluadora PRIDE del Instituto de Neurobiología, 2018-2020.
- Comité de Evaluación del PAPIIT.
- Comisión Dictaminadora del Instituto de Neurobiología, 2017-2019.
- Jefe de Departamento de Neurociencia Cognitiva, Instituto de Fisología Celular, 16 de noviembre, 2017-.

Castro Obregón Susana

- Presidenta la Comisión Permanente de Ingreso, Egreso y Permanencia (CPIEP) del Posgrado en Ciencias Bioquímicas.
- Miembro del subcomité Académico de la Licenciatura en Neurociencias.
- Secretaria Ejecutiva de la Comisión de la Unidad de Biología Molecular.
- Miembro de la Comisión de Seminarios del IFC.
- Jurado Evaluador del Concurso de Oposición Abierto para una plaza de Técnico Académico Titular A de tiempo completo.
- Comité Organizador del III Congreso Nacional de Neurobiología de la Sociedad Mexicana de Bioquímica.
- Coordinación de la Red CYTED-NeuroSur.

Chagoya Hazas Victoria Eugenia

- Miembro de la cartera de evaluadores del CONACyT.
- Apoyo a diferentes programas de posgrado como profesor, tutor y asesor: Facultad de Ciencias: Posgrado en Ciencias Biológicas. Facultad de Química: Posgrado en Ciencias Bioquímicas y Químicas. Facultad de Medicina: Posgrado en Ciencias Biomédicas.
- Revisor de Archivos de Cardiología de México.

- Comisión Multidisciplinaria de la Facultad de Química UNAM.
- Revisor de proyectos de la Fundación Glaxo Smith Kline y Fundación Mexicana para la Salud.
- Revisor de la revista Journal of Pharmacy and Pharmacology.

Coria Ortega Roberto

- Árbitro de proyectos PAPIIT.
- Revisor Proyectos de Ciencia Básica de CONACyT.
- Jefe del Departamento de Genética Molecular del IFC.
- Revisor de manuscritos para publicación en revistas internacionales indizadas: Cells, Journal of Microbiology and Biotechnology, Molecular and Cellular Biology, FEBS Letters.

Del Río Guerra Gabriel

- Miembro de la comisión de cómputo del Instituto de Fisiología Celular.
- Revisor para las revistas Bioinformatics, Microbial Cell Factories, ACS Synthetic Biology, Entropy, Molecules, Scientific Reports, Nucleic Acids Research, Polymers, PeerJ.
- Revisor de proyectos CONACyT.
- Revisor de proyectos PAPIIT.
- Revisor de proyectos Facultad de Medicina-UNAM.
- Organizador del simposium internacional realizado en Canadá, titulado "Mathematics and Computer Science in Modeling and Understanding of Structure and Dynamics of Biomolecules".

Dreyfus Cortés Georges

- Miembro del Subcomité Académico de la Licenciatura en Investigación Biomédica Básica 2010- 2019.
- Miembro Titular de la Academia Nacional de Medicina de México, A.C.
- Evaluador del Área de las Ciencias Biológicas, Químicas y de la Salud del Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica.
- Evaluador de proyectos CONACyT-Ciencia Básica.
- Evaluador de la XXIX edición del Programa "El Verano de la Investigación Científica" 2019.
- Revisor de diversas revistas Internacionales sobre Microbiología.
- Evaluador de proyectos PAPIIT.

- Colaborador Externo de la editorial Fondo de Cultura Económica.

Escalante Alcalde Diana María

- Jefa del departamento de Neurodesarrollo y Fisiología, Enero 2014 a la fecha.
- Miembro del Subcomité Académico de la Licenciatura en Neurociencias.
- Elaboración de una propuesta institucional de infraestrutura del CONACyT para la compra de equipo especializado para el nuevo vivario del IFC. Se otorgaron más de 18 millones de pesos.
- Miembro de Comité de entrevistas para la admisión a la Licenciatura en Neurociencias.
- Miembro del Comité de admisión al Doctorado en Ciencias Biomédicas.
- Miembro del CICUAL.
- Miembro de la Comisión de Bioseguridad.
- Secretaria Ejecutiva de la Unidad de Imagenología del IFC.
- Evaluador de proyectos CONACyT (Ciencia Básica y Fronteras) y PAPIIT.
- Miembro del Comité Editorial del IFC. Creado en Octubre del 2016.
- Miembro de la Comisión Local de Bioseguridad.

Fernández De Miguel Francisco

- Editor Revisor de la revista “Frontiers in Physiology”, sección Membrane Biophysics and Physiology.
- Revisor *ad hoc* de artículos científicos para BMC Neuroscience, Frontiers in Physiology, Frontiers in Cellular Neurosciences, Frontiers in Developmental Neurosciences, Frontiers in Physics, Journal of Neurophysiology, Neuroscience.
- Guest Associate Editor. Frontiers in Physiology. Membrane Physiology and Membrane Biophysics.
- Evaluador de proyectos para el CONACyT.
- Guest Associate Editor. Fundamentals in the 21st Century. Frontiers in Molecular Neuroscience. Suiza.
- Coordinador del Programa de Neurociencias del Centro de Ciencias de la Complejidad.
- Miembro del Comité Académico del Centro de Ciencias de la Complejidad (C3), UNAM.
- Coordinador de la sexta edición del libro de texto "From Neuron to Brain" de Martin, AR., Brown, DA, Diamond, M, Cattaneo, A, y De Miguel FF. Oxford UNiversity Presss. Reino Unido.
- Evaluador de Proyectos de investigación científica y tecnológica presentados al FONCYT, Ministerio de Ciencia, Tecnologia e Innovacion Productiva, Agencia Nacional de

Promoción Científica y Tecnológica, Fondo para la Investigación Científica y Tecnológica, Argentina.

- Evaluador de proyectos PAPIIT.
- Miembro del Consejo Directivo del Consejo Mexicano para la Cultura y las Artes AC (COMCA).

Funes Argüello María Soledad

- Representante del Director del Instituto de Fisiología Celular ante el Comité Académico del Programa de Maestría y Doctorado en Ciencias Bioquímicas (UNAM).
- Coordinadora de enseñanza del Instituto de Fisiología Celular.
- Representante del Director del Instituto de Fisiología Celular ante el Comité Académico del Programa de Maestría y Doctorado en Ciencias Biológicas (UNAM).
- Participación en las entrevistas de admisión del Programa de Doctorado en Ciencias Biológicas. Admisión 2020-1 y 2020-2.
- Tesorera de la Sociedad Mexicana de Bioquímica. Mesa Directiva 2019-2021.
- Responsable de Entidad (Instituto de Fisiología Celular) ante el Programa de Doctorado en Ciencias Biomédicas (UNAM).
- Subsecretaria Tesorera de la Sociedad Mexicana de Bioquímica. Mesa directiva 2017-2019.
- Miembro de la Comisión de Difusión y Divulgación del Instituto de Fisiología Celular.

Furlan Magaril Mayra

- Miembro de la comisión de seminarios. Invitación y coordinación de seminarios institucionales nacionales e internacionales en el Insituto de Fisiología Celular.
- Representate del IFC en la generación de la Orientación Interdisciplinaria de Posgrado en Bioinformática y Biomatemáticas.
- Comisión de la Unidad de Biología Molecular.
- Miembro de la Comisión con perspectiva de Género.
- Evaluación de proyectos PAPIIT y CONACyT.
- Referí de artículos internacionales: Journals: Scientific Reports, Cellular & Molecular Biology Letters y BMC journal.

Galarraga Palacio María Elvira

- Como Miembro y Vicepresidenta de la Sociedad Internacional de Ganglios Basales (IBAGS) apoyar a esta sociedad con el cambio de Presidencia para 2019.

- Revisora de Proyectos de Investigación de PAPIIT-UNAM y CONACyT.
- Revisora de articulos en revistas internacionales para su publicación.

García Sáinz Jesús Adolfo

- Revisor de Proyectos para DGAPA y CONACyT.
- Miembro del Comité Editorial de: European Journal of Pharmacology, Molecular Pharmacology y de Archivos del Instituto Nacional de Cardiología.
- Revisor *Ad Hoc*: Psicopharmacology, Annals of the Brazilian Academy of Sciences, Biochemistry Research International.

Georgellis Dimitris

- Participación en el subcomité de admisión de alumnos del Programa de Maestría y Doctorado en Ciencias bioquímicas, semestre 2019-2.
- Comisión Dictaminadora Instituto de Biotecnología, UNAM. (2018-).
- Representante de Tutores del Instituto de Fisiología Celular ante el Comité Académico del Programa de Maestría y Doctorado en Ciencias Bioquímicas de la UNAM. (2019-) .

Gómora Martínez Juan Carlos

- Miembro de la Comisión de Seminarios institucionales del IFC, desde el 2010.

González Halphen Diego

- Miembro de la Comisión Dictaminadora del Centro de Ciencias Genómicas, Campus Cuernavaca, UNAM, del 27 de junio de 2016 a la fecha.
- Consejero Universitario suplente, representante de los investigadores del Instituto de Fisiología Celular ante el H. Consejo Universitario, UNAM, del 18 de agosto de 2016 a la fecha.
- Miembro de la Comisión de Legislación Universitaria, comisión permanente del H. Consejo Universitario, UNAM; designado por el propio Consejo, del 18 de agosto de 2016 a la fecha.

González Manjarrez Alicia

- Participacion en el programa jovenes hacia la investigacion. alumna: Sheyla Sabel Cruz Cruz y Karen Peralta Estancia del 4 al 29 de Junio de 2019.
- Integrante de la Comisión externa de evaluación del Centro de Investigación Científica de Yucatán (CICY) CONACyT.

- Coordinadora Regional de la Red Latinoamericana de Biología.
- Miembro de la Comisión de Premios de Ciencias Naturales de la Academia Mexicana de Ciencias.
- Miembro de la Comisión Dictaminadora del Instituto de Ecología desde Diciembre de 2015.
- Coordinador del ciclo científico de la Feria Internacional del Libro del Palacio de Minería. Febrero/Marzo 2019.

González Pedrajo Bertha

- Representante del personal académico del Instituto de Fisiología Celular ante el Consejo Técnico de la Investigación Científica.
- Miembro de las comisiones de Reglamentos Internos y de Posgrado del CTIC.
- Miembro del Consejo Interno del IFC.
- Participación del grupo en el seminario departamental de la División de Ciencia Básica del IFC.
- Evaluación de proyectos de investigación para DGAPA, Israel Science Foundation, el Medical Research Council, UK y la Fundación Marcos Moshinsky. Revisora de artículo para las revistas Brazilian Journal of Microbiology y TIP (FES Zaragoza).
- Miembro del Comité Organizador del XLI Congreso Nacional de Microbiología.
- Miembro de la Mesa Directiva de la Sociedad Mexicana de Bioquímica (Subsecretaria Tesorera).
- Miembro de la comisión de bioseguridad del Instituto de Fisiología Celular.

Guerra Crespo Magdalena

- Participación en la inauguración del Laboratorio de Medicina Regenerativa en el Departamento de Cirugía de la Facultad de Medicina de la UNAM, como investigador responsable del laboratorio. marzo de 2019.
- Participación en la reinauguración del Departamento de Cirugía de la Facultad de Medicina de la UNAM.marzo de 2019.
- Evaluador proyectos de investigación de la convocatoria DGAPA-PAPIIT 2019.
- Miembro del comité editorial de la revista Tecnología Digital. Tuxtla Gutiérrez, Chiapas desde su creación (abril del 2011). ISSN: 2007-9400.
- Nombramiento como Representante de los Tutores y Alumnos del IFC en el Comité Académico del Posgrado en Ciencias Biológicas. Periodo 2017-2019.

Hansberg Torres Wilhelm

- Arbitraje de artículos de investigación para revistas Internacionales.
- Arbitraje de proyecto para el PAPIIT.
- Evaluador Fondo SEP-CINVESTAV, Proyecto de Investigación, Área de Ciencias Biológicas y de la Salud.
- Comisión Evaluadora del PRIDE y PAIPA de la Facultad de Química, UNAM.
- Revisión de proyecto de Investigación para la Cátedra Moshinsky.

Hernández Cruz Arturo

- Miembro del Comité Institucional para el Cuidado y Uso de Animales de Laboratorio del IFC 2013-.
- Evaluador de Proyectos de CONACyT y DGAPA 2015-.
- Responsable Técnico del Laboratorio Nacional de Canalopatías del IFC. 2019-.
- Miembro del Subcomité de Admisión al Posgrado en Ciencias Biomédicas 2012-.

Hernández Muñoz Rolando

- Encargado de Seguridad Radiológica del Instituto de Fisiología Celular ante la Comisión Nacional de Seguridad Nuclear y Salvaguardas (CNSNS).

Hiriart Urdanivia Marcia

- Miembro de la Comisión *Ad hoc* para revisar candidatos a plazas en el Centro de Ciencias de la Atmósfera.
- Miembro del Comité Evaluador de la Fundación Miguel Alemán Velasco (2012-2019).
- Miembro del Comité del PECEM, Facultad de Medicina, UNAM.
- Arbitro externo en la evaluación de proyectos PAPIIT, evaluación de proyectos de CONACyT.
- Miembro de la Comisión Dictaminadora del Instituto de Ciencias Físicas, UNAM, Cuernavaca, Mor (2019-2021).
- Miembro del Jurado de las Cátedras Moshinsky.
- Editora Asociada del Frontiers in Pharmacology, revisión de varios artículos al mes y de muchos otros artículos de revistas internacionales como Diabetes Care, Diabetes, J Cell Physiol, J Mol Endocrinology, Am J Physiology, etc.
- Presidente del Jurado del Premio UNAM PUNJA y RNDJA. Docencia 2019.

- Miembro de la Comisión Dictaminadora de Biología, Facultad de Ciencias, UNAM (2019-2021).

Lemus Luis

- Comisión organizadora de seminarios del Instituto de Fisiología Celular. De enero del 2013 a la fecha.
- Miembro de la Comisión de Cómputo del IFC.
- Reviewer editor Frontiers in Psychology. Revisor de cuatro artículos publicados.
- Reviewer editor Frontiers in Integrative Neuroscience (doce artículos revisados).
- Revisor invitado para la revista Neuroscience.
- Revisor invitado para Cerebral Cortex.
- Organizador de la Feria de Carteles del IFC del 2015 a la fecha.

Licona Limon Paula

- Comité Interno para el Cuidado y Uso de Animales de Laboratorio del Instituto de Fisiología Celular.
- Comisión de seminarios institucionales.

López Casillas Fernando

- Integrante del subcomite de admision del Doctorado en Ciencias Biomédicas. Mayo de 2019.
- Miembro de la Comisión Revisora del Área II: Biología y Química (Inconformidades de Dictamines) del Sistema Nacional de Investogadores (Noviembre y Diciembre 2019).
- Representante del Personal Académico del IFC ante el CAABQYS para el periodo agosto 2016 a agosto 2019.
- Miembro de la Comisión Evaluadora del Área de las Ciencias Biológicas, Químicas y de la Salud del Programa de Apoyos para la Superacion del Personal Académico de la UNAM (PASPA) para el periodo mayo 2018 a mayo 2021.

López Colomé Ana María

- Miembro del Patronato de la Fundación "Conde de Valenciana”.
- Jefe de la Unidad de Investigación del Instituto de Oftalmología Conde de Valenciana.
- Miembro de la Comisión Dictaminadora de la Facultad de Medicina, UNAM.
- Editor Regional de la revista "Molecules" (Basilea, Suiza).

- Evaluador de Proyectos PAPIIT/UNAM.
- Consejera Universitaria, Instituto de Fisiología Celular.
- Evaluador de Proyectos CONACyT: Fronteras de la Ciencia.
- Miembro del Comité Directivo de la Maestría México / Francia en "Ciencias de la Visión". Facultad de Medicina, UNAM.
- Jurado del "Premio Estatal de Ciencia y Tecnología 2016, 2017, 2018, 2019: Ciencias de la Salud.
- Miembro de la Comisión Dictaminadora de la Facultad de Veterinaria: Ciencias Aplicadas.
- Revisor de publicaciones para: Cellular Physiology and Biochemistry; Investigative Ophthalmology and Visual Science; Experimental Eye Research; Journal of Cellular Biochemistry.

Macías Silva Marina

- Jefe del Departamento de Biología Celular y Desarrollo del IFC, UNAM.
- Miembro la Comisión Dictaminadora del CAABQYS, de la Facultad de Química, UNAM (a partir de octubre del 2018).
- Miembro del Comité de Seguimiento a Nuevos Investigadores, en particular de la Dra. Daniela Araiza Olivera Toro, del Instituto de Química de la UNAM.
- Evaluador *Ad Hoc* de proyectos de investigación PAPIIT-DGAPA, UNAM.
- Evaluador *Ad Hoc* de proyectos de investigación CONACyT.
- Miembro de la Comisión del Bioterio y del CICUAL del IFC.
- Colaborador del Laboratorio Nacional LaNSBioDyt (Laboratorio Nacional de Soluciones Biomiméticas para Diagnóstico y Terapia) de la Facultad de Ciencias, UNAM.
- Revisor *Ad Hoc* para las revistas internacionales: Neurochemical Research, Cell Biol Int, y Science Signalling.

Mas Oliva Jaime

- Miembro del Comité Editorial de Gaceta Médica de México. Academia Nacional de Medicina.
- Revisor de proyectos presentados al CONACyT dentro de las convocatorias de Problemas Nacionales y Ciencias Básicas.
- Presidente del Jurado Calificador del Premio Dr. Jorge Rosenkranz 2019 (Roche México).
- Miembro del Consejo Consultor de Archives of Medical Research (Elsevier).
- Revisor de proyectos de investigación presentados al programa PAPIIT de la Dirección General de Asuntos del Personal Académico (DGAPA) de la UNAM.

Massieu Trigo María de Lourdes

- Secretaria Académica del Instituto de Fisiología Celular a partir de enero del 2018.
- Miembro de la Comisión del PRIDE de la Facultad de Medicina.
- Arbitro de artículos en revistas internacionales: CNS and Therapeutics, Neurochemistry International (2 revisiones), Journal of Biological Inorganic Chemistry, Frontiers in Cellular Neuroscience, Chemical Research in Toxicology.
- Revisor de proyectos para la Agencia de Promoción Científica y Tecnológica.
- Fondo para la investigación Científica y Tecnológica (FONCyT) Argentina.
- Revisor de proyectos PAPIIT.

Morán Andrade Julio

- Jefe del Departamento de Neuropatología Molecular del Instituto de Fisiología Celular, UNAM. A partir de enero 2018- .
- Miembro del Comité Editorial de la revista Escuela Nacional Preparatoria 2015- .
- Miembro de la Comisión Dictaminadora Facultad de Psicología, UNAM, 2014- .
- Miembro de la Comisión Evaluadora del PRIDE de la Facultad de Ciencias, UNAM, 2016-.
- Miembro de la Comisión Dictaminadora Instituto de Investigaciones Biomédicas, UNAM, 2010- .
- Miembro de la Comisión Evaluadora del PRIDE del Instituto de Química, UNAM, 2015- .
- Miembro de la Comisión de Investigación y Ética de la Facultad de Medicina, UNAM, 2016- .
- Miembro de la Comisión Evaluadora del PRIDE del Instituto de Ecología, UNAM, 2016-.
- Miembro de la Comisión Evaluadora del PRIDE del Centro de Ciencias Genómicas, UNAM, 2016-.
- Miembro de la Comisión Dictaminadora Instituto de Neurobiología, UNAM, 2018-.

Navarro González Rosa Estela

- Miembro del Comité Organizador del Simposio Teórico-Práctico de Edición Genética por CRISPR-Cas9. Realizado en el Instituto de Fisiología Celular de la UNAM. Octubre de 2019.
- Revisora de artículos para la revista Peer J.
- Representante de Tutores ante el Program de Maestría y Doctorado en Ciencias Bioquímicas (2019-).
- Participante de la Red de evaluación del efecto tóxico de nanopartículas Sinanotox.

- Revisora de varios Proyectos de PAPIIT.
- Miembro del Comité Editorial del Instituto de Fisiología Celular, UNAM. Desde 2016.
- Revisora de artículos para la revista PLoS One.
- Participación en la Mesa Redonda: De Estudiante de Doctorado a Investigador. Instituto de Química. Marzo de 2019.
- Miembro de la Comisión de Biblioteca desde 2018.

Pasantes Ordóñez Herminia

- Participación en el subcomité académico de la Licenciatura en Neurociencias.

Peraza Reyes Leonardo

- Miembro de la comisión de seminarios del Instituto de Fisiología Celular, UNAM. 2015-2019.
- Comisión *Ad Hoc* para la elección de representantes de los tutores y alumnos para el Comité Académico del Programa de Maestría y Doctorado en Ciencias Bioquímicas, UNAM. 2019.
- Miembro del Comité central de la Rama de Biología Molecular y Celular de Hongos de la Sociedad Mexicana de Bioquímica, Noviembre 2017 a la fecha.
- Comisión Ad Hoc para la elección para representantes de los tutores y alumnos para el Comité Académico del Programa de Posgrado en Ciencias Biológicas, UNAM. 2019.

Pérez de la Mora Miguel

- Árbitro de la revista Behavioural Brain Research.
- Árbitro externo en la evaluación de proyectos inscritos en el programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica (PAPIIT).
- Árbitro de la revista: Molecular Neurobiology.
- Árbitro de la revista: Neuropharmacoloy.
- Arbitro de la revista: Pharmacological Reports.
- Arbitro de la revista: Neuroscience Letters.
- Evaluador de proyectos de investigación correspondientes a la Convocatoria de Ciencias Básicas del CONACyT.
- Dirección de la Revista Ciencia de la Academía Mexicana de Ciencias A.C. a partir del 2000.

Pérez Martínez Xóchitl

- Miembro de la Comisión de Cómputo del IFC, UNAM.
- Participación en los exámenes de Admisión del Posgrado en Ciencias Biomédicas. Mayo de 2019.
- Representante vocal de investigadores ante el Consejo Académico del Área de las Ciencias Biológicas, Químicas y de la Salud (CAABQYS).

Pérez Montfort Ruy

- Miembro del Comité de Reconsideración Académica del Programa de Apoyo a Proyectos de investigación e Innovación Tecnológica PAPIIT de la Convocatoria 2020.
- Miembro del Editorial Board de la Revista Current Medicinal Chemistry de Bentham Science Publishers, Ltd. (período de nombramiento indefinido).
- Miembro del Editorial Board de la Revista The Open Medicinal Chemistry Journal de Bentham Science Publishers, Ltd. (periodo de nombramiento indefinido).
- Miembro del Editorial Board de la Revista Letters in Drug Design & Discovery (periodo de nombramiento indefinido).
- Miembro del Consejo Editorial de la Revista Investigación en Salud (período de nombramiento indefinido).
- Miembro del Comité Editorial Externo de la Revista Ciencia UANL (período de nombramiento indefinido).
- Evaluador externo de proyectos de investigación del PAPIIT, UNAM, 2019.

Recillas Targa Félix

- Director del Instituto de Fisiología Celular de la UNAM a partir del 17 de Octubre de 2017.
- Miembro del “Editorial Board” de la revista Epigenetics, febrero 2014 a la fecha.
- Miembro del "Editorial Board" de la Revista Epigenetics Insights a partir de 2018.
- Miembro del Comité Editorial de la Revista Ciencia UANL, revista de divulgación científica y tecnológica de la Universidad de Nuevo León, marzo 2014 a la fecha.
- Revisor *Ad Hoc* de las revistas: Epigenetics, Bioinformatics; Epigenetics & Chromatin; BMC Genomics y Frontiers in Genetics (RNA section).
- Miembro de la Comisión Especial del Programa de Primas al Desempeño del Personal Académico de Tiempo Completo nivel D de la UNAM (PRIDE D) del Área de las Ciencias Biológicas, Química y de la Salud (CAABQyS), UNAM. 27 de Junio 2016-.

- Miembro del Consejo Académico del Área de las Ciencias Biológicas, Química y de la Salud (CAABQyS) y formo parte de la Comisión Permanente de Planeación y Evaluación, de la Comisión Permanente de Personal Académico y del Pleno de este Consejo, como Director del Instituto de Fisiología Celular de la UNAM, a partir del 17 de Octubre del 2017.
- Consejero Universitario, Universidad Nacional Autónoma de México, a partir del 17 de Octubre de 2017.
- Consejero Técnico de la Investigación Científica de la UNAM, con participación en las comisiones especiales: Comisión para el Estímulo Especial "Efrén C. Del Pozo" para Técnicos Académicos del Instituto de Investigaciones Biomédicas (Presidente), Comisión para la Evaluación de Técnicos Académicos; Comisión de Evaluación Asuteso UPEID y Cátedra para profesores "Jesús Romo Armería" perteneciente al Instituto de Química, a partir de Octubre de 2017.
- Miembro de la Comisión de Incorporación y Revalidación de Estudios y de Títulos y Grados del Consejo Universitario de la UNAM a partir del 7 de Junio de 2018.
- Miembro de la Comisión de Asuntos Académico Administrativo (CAAA) de la Coordinación de la Investigación Científica, UNAM a partir del 1 de Junio de 2018 al 24 de octubre de 2019.
- Miembro de la Comisión Ampliada de Becas posdoctorales de la CAAA de la Coordinación de la Investigación Científica, UNAM a partir del 11 de Abril de 2018.
- Evaluador de proyectos científicos: CONACyT y DGAPA-PAPIIT.
- Presidente de la Comisión *ad hoc* para Premios y Distinciones del CTIC, relativo a la propuesta del Consejo Interno del Centro de Ciencias Genómicas, para que el Dr. Pedro Julio Collado Vides, adscrito a dicha entidad, sea nombrado Investigador Emérito. Octubre 2019.

Romo Trujillo Ranulfo

- Editor de la sección Beharioral and Cognitive Neuroscicnce de la revista Neuroscience (IBRO).
- Editor asociado: eLife y eNeuro.
- Revisor *ad hoc*: Nature Reviews Neuroscience, Journal of Neuroscience, Current Biology, European Journal of Neuroscience, Journal of Neurophysiology, Journal of Computational Neuroscience, Cerebral Cortex, Experimental Brain Research, Neuroimage, Brain, PLoS Biology, PNAS (editor asociado), Science, Nature, Nature Neuroscience.
- Editor Asociado: Proress in Neurobiology y Neuroscience Research.
- Miembro del comité editorial de la revista Neuron.
- Coordinador del comité de evaluación de Proyectos Milenio del Gobierno de Chile.
- Editor Asociado de la revista Journal of Cognitive Neuroscience, MIT, E.U.A.
- Editor Asociado de la revista Journal de Physiologie, Paris, Francia.

Rosenbaum Emir Tamara

- Miembro de la Comisión de Bioética y Ética Científica del IFC.
- Representante de investigadores electa ante el Consejo Interno del IFC.

Rossi Pool Román

- Revisor *ad hoc*: Neuroscience (IBRO).
- Revisor *ad hoc*: Frontiers in Computational Neuroscience.
- Revisor *ad hoc*: Plos Biology.
- Revisor *ad hoc*: Frontiers in Systems Neuroscience.

Salceda Sacanelles Rocío

- Participación, como representante del Dr. Félix Recillas Targa, en el Seminario Universitario Interdisciplinario sobre Envejecimiento y Vejez (SUIEV).
- Miembro de la Comisión del PASPA, UNAM.
- Miembro de la Comisión Evaluadora del programa de Becas Posdoctorales DGAPA, UNAM.
- Evaluadora en la Convocatoria ConTex CONACYT 2019 para Proyectos de Investigación Conjunta.
- Evaluadora en la Convocatoria para Estancias Posdoctorales en Instituciones Académicas o de investigación con sede en Europa o América, 2019. Secretaría de Educación Ciencia, Tecnología e Innovación.
- Miembro Comisión Dictaminadora para el concurso de oposición abierto para una plaza de Técnico Académico Asociado C (Biología Celular, microscopía electrónica) Facultad de Ciencias, UNAM. 2019.
- Miembro del Comité Editorial de la Revista de Educación Bioquímica.
- Revisor *ad hoc* de distintas revistas, como: IOVS, Cell Physiol Biochem, Peer J, Arch Biochem Biophys, Frontiers Aging Neurosci, Frontiers Cellular Neurosci, Bioscience Report.
- Revisor *ad hoc* del CONACyT y PAPIIT- UNAM.
- Participación en el Subcomité de Admisión del Posgrado en Ciencias Biomédicas, semestre 2019-1.
- Participación en el Subcomité de Admisión Posgrado en Ciencias Biológicas, semestre 2020-2.

Sotres Bayón Francisco

- Revisor de Manuscritos en: Nature Neuroscience, Journal of Neuroscience, eNeuro, Biological Psychiatry, Neuropshychopharmacology, The International Journal of Neuropshychopharmacology, Frontiers in Behavioral Neuroscience, Frontiers in Neural Circuits, Frontiers in Molecular Neuroscience ,Neuroscience, Behavioral Neuroscience, Behavioral Brain Research, Psychopharmacology , Neurobiology of Learning and Memory, Physiology & Behavior, Neuroscience Letters, Progress in Neuro psychopharmacology and Biological Psychiatry, Molecular Psychiatry, Salud Mental.
- Tutor de los siguientes programas: doctorado en Ciencias Biomédicas (UNAM), maestría y doctorado en Ciencias Bioquímicas (UNAM), maestría en Ciencias Biológicas (UNAM), maestría del Instituto de Neurobiología (UNAM), doctorado en Psicología (UNAM) y maestría y doctorado de Farmacologia del CINVESTAV (IPN).
- Subcomisión con perspectiva de género (noviembre 2018 a la fecha).
- Comité Académico del Posgrado de Ciencias Bioquímicas (octubre 2016-2019).
- Comisión Institucional para el Cuidado y Uso de Animales de Laboratorio (agosto 2015 a la fecha).

Tapia Ibargüengoytia Ricardo

- Jurado del Premio Dra. Aurora Arnaiz Amigo a la mejor tesis de doctorado en Bioética, UNAM.

Tecuapetla Aguilar Fatuel

- CONACyT Revisor de proyectos en la convocatoria de Ciencia Básica.
- Revisor de artículo científico para la revista Neuroscience (https://www.journals.elsevier.com/neuroscience/).
- Revisor de artículo científico para la revista Neuron (http://www.cell.com/neuron/home).
- CONACyT Revisor de proyecto de la convocatoria "PDC Problemas Nacionales".
- PAPIIT-DGAPA-UNAM Revisor de proyectos del Área de las Ciencias Biológicas, Químicas y de la Salud del Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica (PAPIIT - UNAM).
- Revisor de artículo científico para la revista eLife (http://elifesciences.org/).

Torres Larios Alfredo

- Jefe del Departamento de Bioquímica y Biología Estructural del Instituto de Fisiología Celular, UNAM. A partir de Noviembre 2017.
- Revisor de proyectos para el Advanced Photon Source (APS) en Argonne, Illinois, USA.

- Miembro del subcomité de admisión al Doctorado en Ciencias Biomédicas. Semestre, 2020-2.

Torres Quiroz Francisco

- Representante de tutores del IFC ante el Programa de Doctorado en Ciencias Biomédicas. Desde diciembre 2017.
- Participación como evaluador de proyecto del Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica (PAPIIT) convocatoria 2020.

Tovar y Romo Luis Bernardo

- Miembro de los subcomités de admisión al PDCB en el semestre 2020-2.
- Miembro del subcomité de admisión a la Licenciatura en Neurociencias 2019.
- Revisor de las revistas: Frontiers in Cellular Neuroscience, Neurodegenerative Diseases, Brain Research, Molecular Neurodegeneration, Neuroscience, Stems Cells International, Molecular Neurobiology, Mediators of Inflammation, Journal of Neuroinflammation, Cellular Physiology and Biochemistry, Neurochemical Research, Neurochemistry International, IUBMB Life, Biomedicine & Pharmacotherapy, Frontiers in Cell and Developmental Biology, Neurotoxicity Research.
- Miembro del Subcomité Académico de la Licenciatura en Investigación Biomédica Básica como encargado de la Licenciatura en el Instituto de Fisiología Celular.
- Miembro de la Comisión de la Unidad de Biología Molecular del Instituto de Fisiología Celular.
- Miembro del Editorial Board de Neurochemical Research.
- Editor Asociado Invitado de la sección Molecular Medicine de Frontiers in Cell and Developmental Biology.
- Miembro del Committee for Aid and Education in Neurochemsitry de la International Society for Neurochemistry (2019-2022).
- Editor del Reserach Topic "Mechanisms of neuronal recovery in the central nervous system" en las Revistas Frontiers in Cell and Developmental Biology and Frontiers in Cellular Neuroscience.

Uribe Carvajal Salvador

- Comisión Dictaminadora de la Facultad de Medicina, UNAM. Desde Noviembre de 2019.
- Evaluador de Proyectos de la Fundación Fulbright-García Robles. Noviembre, 2019.
- Comisión del PRIDE en el Instituto de Fisiología Celular. Desde Febrero de 2016.

Vaca Domínguez Luis

- Miembro del Comité de contratación del Instituto de Neurobiología, UNAM.
- Secretario de Vinculación del Instituto de Fisiología Celular.

Velasco Veláquez Iván

- Miembro de subcomité de admisión N° 3 que evaluó a los aspirantes de la Convocatoria 2020-2 al Programa de Doctorado en Ciencias Biomédicas. Octubre 2019.
- Invitaciones aceptadas para arbitrar manuscritos enviados a Bioscience Reports, Cell Biology International y PLoS Neglected Tropical Diseases.
- Representante suplente del personal académico del Instituto de Fisiología Celular ante el Consejo Técnico de la Investigación Científica.
- Designación por parte del Consejo Académico del Área de las Ciencias Biológicas, Químicas y de la Salud para participar en el Comité Evaluador del Área de las Ciencias Biológicas, Químicas y de la Salud del Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica (PAPIIT) de la Dirección General de Asuntos del Personal Académico, UNAM .
- Co-orgnizador del Simposio Chemical transmission: “The key to understand brain function”, en homenaje al Dr. Ricardo Tapia, Investigador emérito del IFC. Evento organizado por la Facultad de Química y el IFC. UNAM 23 y 24 de abril de 2019.
- Miembro del Comité básico de la XXXIII Reunión Anual de Investigación del Instituto Nacional de Neurología y Neurocirugía "Manuel Velasco Suárez". Abril 2019.
- Miembro de la Comisión Dictaminadora del área Biomédica, Facultad de Medicina, UNAM.

Valdés Rodríguez Julián

- Coordinador de los Seminarios Semanales de la División de Investigación Básica del Instituto de Fisiología Celular.
- Miembro del comité organizador del Simposio Teórico-Práctico de edición genética por CRISPR-Cas9. IFC, UNAM 2019.
- Obtención de Concurso de Oposición Abierto (COA) para la plaza de Investigador Titula A de T.C en el departamento de Biología Celular y del Desarrollo.
- Integrante de la comisión *ad hoc* para el proceso de elección de representantes de tutores y alumnos del comité académico del programa de Doctorado en Ciencias Biomédicas.

PROGRAMAS DE SUPERACIÓN ACADÉMICA

Programas de Superación Académica en la UNAM

1. Alcántara Hernández Rocío. Curso Introducción a la Bioética. Comisión de ética académica y responsabilidad científica (CEARC) a través de Secretaría de Educación Abierta y Continua de la Facultad de Ciencias, UNAM, 19 de noviembre 2019 al 5 de febrero de 2020.

2. Aparicio Juárez Ariadna. Taller de Manejo de roedores de Laboratorio. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 11 al 13 de febrero, 4 al 6 de marzo, 19 al 21 de agosto, 28 al 30 de octubre, 2 al 4 de diciembre de 2019.

3. Ayala Méndez Xóchitl Gabriela. Taller de Manejo de roedores de Laboratorio. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 11 al 13 de febrero, 4 al 6 de marzo, 19 al 21 de agosto, 28 al 30 de octubre, 2 al 4 de diciembre de 2019.

4. Códiz Huerta María Guadalupe. Curso-taller de Introducción al Análisis de Fragmentos (Microsatélites). Instituto de Biología, UNAM, 20 y 21 de junio de 2019.

5. Coello Coutiño Gerardo. Curso Diseño y administración de redes segmentadas con VLANs, impartido por el contratista Beamliners, sobre el manejo y administración de la nueva infraestructura de red del IFC, noviembre y diciembre 2019.

6. Delgado Coello Blanca Alicia. Curso Elaboración de material didáctico digital. Facultad de Medicina, UNAM, 14 de mayo al 27 de Junio de 2019.

7. Domínguez Macouzet María Guadalupe. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

8. Escalante Gonzalbo Ana María. Curso Diseño y administración de redes segmentadas con VLANs, impartido por el contratista Beamliners, sobre el manejo y administración de la nueva infraestructura de red del IFC, noviembre y diciembre 2019.

9. Escobedo Avila Itzel. Curso Estrategias didácticas para reforzar conocimientos en el laboratorio de química y biología. DGAPA, UNAM, 22 al 26 julio de 2019.

10. Escobedo Avila Itzel. Curso Introducción a la Bioseguridad. División de Investigación, Facultad de Medicina, UNAM, 19 de febrero de 2019.

11. Guerrero Avendaño Georgina. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

12. Guerrero Avendaño Georgina. Instructor en el Simposio Teórico-Práctico de edición Genética por CRISPR-Cas9. Instituto de Fisiología Celular, UNAM, 28 al 31 de octubre de 2019.

13. Jiménez Pérez Nicolás. Asistencia al curso de capacitación Microscopía electrónica de transmisión y barrido aplicada a las ciencias biológicas. Impartido por la Secretaria de Educación Continua de la Facultad de Medicina Veterinaria y Zootecnia de la UNAM, 21 al 23 de octubre de 2019.

14. Malagón Rivero Héctor Alfonso. Taller de manejo de roedores de laboratorio. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 11 al 13 de febrero, 4 al 6 de marzo, 19 al 21 de agosto, 28 al 30 de octubre, 2 al 4 de diciembre de 2019.

15. Malagón Rivero Héctor Alfonso. Manejo y Cuidados de animales de Laboratorio. clase impartida en el Taller: Investigación en plantas medicinales de la etnobotánica a los fitomedicamentos, en la Facultad de Ciencias-UNAM, 6 de noviembre de 2019.

16. Malagón Rivero Héctor Alfonso. 3 °Coloquio Estudiantil de Fisiología Animal Comparada, Ponente con el tema “Técnicas en el estudio del corazón en modelos animales”, en la Facultad de Ciencias-UNAM, 4 de diciembre de 2019.

17. Mendoza Martínez Ariann. Obtención de grado de Doctorado mediante defensa de Tesis con el titulo “El papel de los factores transcripcionales NapA y SrrA en la respuesta antioxidante y la diferenciación celular en el hongo Aspergillus nidulans”. Programa de Doctorado en Ciencias Bioquímicas. Tutor: Dr. Jesús Aguirre Linares. Fecha de obtención de grado 13 de junio de 2019.

18. Moncada Hernández Sandra Guillermina. Seminarios mensuales de actualización dirigidos a profesores de la asignatura Informática Biomédica. Facultad de Medicina, Departamento de Informática Biomédica, UNAM, 2019.

19. Moncada Hernández Sandra Guillermina. Asistencia a la XVII Conferencia Internacional sobre Bibliotecas Universitarias. Coordinación de Humanidades, UNAM, 23 al 25 de octubre de 2019.

20. Moncada Hernández Sandra Guillermina. Reuniones convocadas por la D.G.B. para la operación y uso de las adquisiciones de libros a través del Sistema Institucional de Compras. Dirección General de Proveduría, UNAM, febrero 2019.

21. Moncada Hernández Sandra Guillermina. Curso “Capacitación en serio. Haz de tus cursos un aprendizaje inolvidable y entretenido”. Programa de Actualización Profesional 2019, Dirección General de Bibliotecas, UNAM, 12 al 31 de agosto de 2019.

22. Moreno Alvarez Paola. Asistencia al Taller de formación y actualización docente en ciencias de la salud. Modalidad virtual. Facultad de Medicina, UNAM, 25 de abril al 27 de mayo de 2019.

23. Ongay Larios Laura María. Curso taller Introducción al análisis de fragmentos (Microsatélites). Impartido por especialistas de los Institutos de Biología y de Investigaciones Biomédicas, así como de Thermofisher Scientific. Instituto de Biología, UNAM, 21 de junio de 2020.

24. Paredes Díaz Rodolfo. Asistencia al curso de Microscopía electrónica de barrido y microanálisis por dispersión de energía. Impartido por Jeol de México, S.A. de C.V. en el Instituto de Fisiología Celular, UNAM, 29 al 30 de enero de 2019.

25. Peña Segura Claudia. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

26. Pérez Molina Rosario. Simposio Teórico-Práctico de edición Genética por CRISPR-Cas9. Instituto de Fisiología Celular, UNAM, 28 al 31 de octubre de 2019.

27. Prior González Mara Guadalupe. Curso de manejo de Crióstato. Impartido en la Unidad de Histología. Instituto de Fisiología Celular, UNAM, 12 al 14 de Febrero de 2019.

28. Prior González Mara Guadalupe. Curso Teórico de Microscopia óptica y electrónica Curso Práctico de los microscopios Axio Zoom y Confocal LSM 800. Impartido en la Unidad de Imagenología, Instituto de Fisiología Celular, UNAM, 18 al 22 de febrero de 2019.

29. Prior González Mara Guadalupe. Taller de manejo de roedores de laboratorio. Unidad Académica del Bioterio del Instituto de Fisiología Celular, UNAM, 27 al 29 de mayo de 2019.

30. Ramírez Graullera Yoás Saimon. Primer semestre del Programa de Maestría en Ciencia e Ingeniería de la Computación, UNAM, semestre 2020-1.

31. Ramos Balderas José Luis. Curso Dominio del idioma inglés nivel 4. Escuela Nacional de Lenguas, Lingüística y Traducción. UNAM, 15 de enero al 20 de junio de 2019.

32. Rincón Heredia Ruth. Impartición un curso *ad-hoc* “Curso Teórico-Práctico de Inmunohistoquímica”. Unidad de Imagenología, IFC-UNAM, 2019.

33. Rincón Heredia Ruth. Instructor en Latin American Training Program 2019. Enlightening the brain: light as a tool for understanding the function of the nervous system. Instituto de Fisiología Celular, UNAM, 26 de agosto al 13 de septiembre de 2019.

34. Rincón Heredia Ruth. Ponente en el XIII Curso Institucional de Microscopía del Instituto de Investigaciones Biomédicas, Unidad de Microscopía del Instituto de Investigaciones Biomédicas, UNAM, 22 al 26 de abril de 2019.

35. Rincón Heredia Ruth. Organización del Curso teórico práctico de microscopía fotónica y electrónica. Instituto de Fisiología Celular, UNAM, 18 al 22 de febrero de 2019.

36. Rincón Heredia Ruth. Ponente del Curso teórico práctico de microscopía fotónica y electrónica. Instituto de Fisiología Celular, UNAM, 19 de febrero de 2019.

37. Rincón Heredia Ruth. Asistencia al curso de capacitación Microscopía electrónica de transmisión y barrido aplicada a las ciencias biológicas. Impartido por la Secretaria de Educación Continua de la Facultad de Medicina Veterinaria y Zootecnia de la UNAM, 21 al 23 de octubre de 2019.

38. Rincón Heredia Ruth. Asistencia al curso de Microscopía electrónica de barrido y microanálisis por dispersión de energía. Impartido por Jeol de México, S.A. de C.V. en el Instituto de Fisiología Celular, UNAM, 29 al 30 de enero de 2019.

39. Rincón Heredia Ruth. Asistencia al XIII Curso Institucional de Microscopia IIBO-UNAM, Instituto de Investigaciones Biomédicas, UNAM, 22 al 26 de abril de 2019.

40. Rivera Cerecedo Claudia Verónica. Médico Veterinario Certificado por CONCERVET A.C. en la Práctica de la Medicina Veterinaria y Zootecnia en Animales de Laboratorio (2016-2021).

41. Rivera Cerecedo Claudia Verónica. Taller de Manejo de roedores de Laboratorio. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 11 al 13 de febrero, 4 al 6 de marzo, 19 al 21 de agosto, 28 al 30 de octubre, 2 al 4 de diciembre de 2019.

42. Rivera Cerecedo Claudia Verónica. Curso Prácticas de Higiene y Seguridad, para el Trabajo en Laboratorios de Investigación Científica. Instituto de Fisiología Celular, UNAM, 4 de marzo y 5 de septiembre de 2019.

43. Rivera Cerecedo Claudia Verónica. Curso de Cirugía Básica en Roedores. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 27 al 29 de mayo, 7 al 9 de octubre de 2019.

44. Rivera Cerecedo Claudia Verónica. Estancia práctica en producción, cuidado y uso de animales de laboratorio. Instituto de Fisiología Celular, UNAM. Unidad Académica Bioterio, 2019.

45. Rodríguez Montaño Sandra Daniela. Asistencia a la transmisión del curso Cerebro, emociones y violencia. impartió la Dra. Feggy Ostrosky, en sede AAPAUNAM, 12 y 14 de noviembre del 2019.

46. Rodríguez Rangel Claudia. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

47. Rosas Arellano Abraham. Latin American training program, Society for Neurosciences. Instituto de Fisiología Celular, UNAM, 2019.

48. Rosas Arellano Abraham. Workshop on muscle ear dissection and electron microscopy. Instituto de Neurobiología, UNAM, noviembre 2019.

49. Rosas Arellano Abraham. Asistencia al curso de capacitación Microscopía electrónica de transmisión y barrido aplicada a las ciencias biológicas. Impartido por la Secretaria de Educación Continua de la Facultad de Medicina Veterinaria y Zootecnia de la UNAM, 21 al 23 de octubre de 2019.

50. Rosas Arellano Abraham. Asistencia al curso de Microscopía electrónica de barrido y microanálisis por dispersión de energía. Impartido por Jeol de México, S.A. de C.V. en el Instituto de Fisiología Celular, UNAM, 29 al 30 de enero de 2019.

51. Salinas Velázquez Laura Silvia. Instructor en el Simposio Teórico-Práctico de edición Genética por CRISPR-Cas9. Instituto de Fisiología Celular, UNAM, 28 al 31 de octubre de 2019.

52. Sánchez Chávez Gustavo. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

53. Sánchez González Olivia. Curso práctico del microscopio confocal LSM800. Instituto de Fisiología Celular, UNAM, 21 y 22 de febrero de 2019.

54. Sánchez Sánchez Norma. Asistencia al Simposio Teórico-Práctico de edición Genética por CRISPR-Cas9. Instituto de Fisiología Celular, UNAM, 28 al 31 de octubre de 2019.

55. Sánchez Soto María del Carmen. Curso de reentrenamiento de personal ocupacionalmente expuesto a radiación (POE). Auditorio 2 de Neurociencias del Instituto de Fisiología Celular, UNAM, 2019.

56. Sosa Garrocho Marcela. Asistencia al Simposio Teórico-Práctico de edición Genética por CRISPR-Cas9. Instituto de Fisiología Celular, UNAM, 28 al 31 de octubre de 2019.

Programas de Superación Académica Fuera de la UNAM

1. Alcántara Hernández Rocío. Curso PreCongreso VII de la Rama de Transducción de Señales de la SMB. CINVESTAV Sur, 29 al 31 de julio de 2019.

2. Aparicio Juárez Ariadna. Curso introductorio de edición genética por CRISPR/Cas 9. Instalaciones de Thermo Fisher Scientific en la Ciudad de México. 24 al 27 de septiembre de 2019.

3. Aparicio Juárez Ariadna. Primer seminario de CRISPR. Instalaciones de Thermo Fisher Scientific en la Ciudad de México. 30 de agosto de 2019.

4. Aparicio Juárez Ariadna. Participación en las jornadas científicas de actualización en Biología Molecular y Biología Celular. Organizado por Uniparts en la Ciudad de México. 26 y 27 de agosto de 2019.

5. Aparicio Juárez Ariadna. Estancia en el laboratorio del Dr. Lluís Montoliu. Investigador Científico del CNB-CSIC de Madrid, España. 18 de mayo al 8 de junio de 2019.

6. Aparicio Juárez Ariadna. Curso de técnicas de Ingeniería Reproductiva en el ratón método CARD. Lluís Montoliu. Universidad de Salamanca, España. 29 al 31 de mayo de 2019.

7. Ayala Méndez Xóchitl Gabriela. Minicourse On Line. Basics of Mouse Genetics. The Jackson Laboratory. 26 de Agosto de 2019.

8. Barbosa Castillo Juan Manuel. Certificación en el programa Microsoft Word 2016. Word 2016 Academic. Folio: CAL4T-VHPGX. Serie: CLSS1801CT. Diplomado registro: STPS CTE-050608QL5-001. 2 de marzo de 2019.

9. Chiquete Félix Natalia. 4° Simposio Científica Senna-ATCC; "Cultivo Celular, Inmunidad y Medicina Traslaciona". INMEGEN. 8 de mayo de 2019.

10. Crespo Ramírez Minerva. Curso de Biología Molecular. Unidad de investigación CMN La Raza. 7 de enero al 4 de marzo de 2019.

11. Crespo Ramírez Minerva. Curso de Inmunilogía. Unidad de investigación CMN La Raza. 25 de marzo al 17 de junio de 2019.

12. Galván Lobato Aurey. Curso de AutoCAD. eduMAC. Digital Arts Center. 2019.

13. Jiménez Pérez Nicolas. Curso de capacitación para el manejo del Microscopio Electrónico de Barrido JSM-5410LV. Impartido por Ingenieros de la compañía JEOL de México. Febrero de 2019.

14. Jiménez Pérez Nicolas. Curso de capacitación para el manejo del Microscopio estereoscópico con fluorescencia Axio ZoomV16 con sistema Apotome. Impartido por Ingenieros de la compañía Carl Zeiss de México. Febrero 2019.

15. Lee Rivera Irene. Curso PreCongreso VII de la Rama de Transducción de Señales de la SMB. CINVESTAV Sur, 29 al 31 de julio de 2019.

16. Llorente Gil Itzel Alejandra. Platica Cell Culture Fundamentals: Your Questions Answered. Impartido por Científica Senna S.A de C.V. y ATCC. 2019.

17. López Hernández Edith. Curso PreCongreso VII de la Rama de Transducción de Señales de la SMB. CINVESTAV Sur, 29 al 31 de julio de 2019.

18. Mendoza Rodríguez Valentin. Curso de Excel. Impartido por eduMac, Digital Arts Center. Ciudad de México, 11 de noviembre de 2019.

19. Moncada Hernández Sandra Guillermina. Certificación de “Google for Education”, a través de una beca otorgada en el Departamento de Informática Biomédica como Educador Google Nivel 1, 29 de noviembre de 2018 a enero de 2019.

20. Moncada Hernández Sandra Guillermina. Gamification. University of Pennsylvania. USA. En línea, 2 de septiembre al 5 de diciembre de 2019.

21. Ortínez Benavides Manuel. Curso de AutoCAD. eduMAC. Digital Arts Center. 2019.

22. Poot Hernández Augusto César. Curso precongreso: 1er Simposio de Mapeo y Navegación Cerebral. XXY Congreso Mexicano e Internacional de Cirugía Neurológica 2019. Sociedad Mexicana de Cirugía Neurológica, A.C. Centro Médico Siglo XXI. Julio 2019.

23. Rodríguez Montaño Sandra Daniela. Asistencia al Curso-Taller Histotecnología, Generalidades y Aplicaciones en Tópicos Selectos de: Dermatopatología, Enfermedades del Hígado, Cáncer de Mama y Cérvico- Uterino, Celaya, Guanajuato, del 1 al 3 de febrero de 2019.

24. Rodríguez Montaño Sandra Daniela. Asistencia al Curso-Taller Tópicos Selectos de Histotecnología, Oaxaca de Juárez, del 20 al 22 de septiembre de 2019.

25. Romero Ávila María Teresa. Curso PreCongreso VII de la Rama de Transducción de Señales de la SMB. CINVESTAV Sur, 29 al 31 de julio de 2019.

26. Rosas Arellano Abraham. Course 219R - ES&H Refresher - Orientation. National Accelerator Laboratory, SLAC - Stanford University, USA. Cyber course. Julio 2019.

27. Rosas Arellano Abraham. Course 115 - GERT. National Accelerator Laboratory, SLAC - Stanford University, USA. Cyber course. Julio 2019.

28. Rosas Arellano Abraham. Course CS100 - Cyber Security for Lab Users. National Accelerator Laboratory, SLAC - Stanford University, USA. Cyber course.

29. Sánchez Sevilla Maria de Luordes. Curso teórico-práctico Cromatografía de líquidos-espectometría de masas y sus aplicaciones en productos naturales. Centro de Investigación Científica de Yucatán, A.C. 4 al 8 de febrero del 2019.

INVESTIGADORES VISITANTES

1) Fernández De Miguel Francisco: Sanz Martín Araceli, Dra. Sanz Martín. Procedencia: Universidad de Guadalajara. Motivo de la visita: Impartió conferencia: La neurobiología de la violencia infant. Fecha inicio: 30-mayo-2019. Fecha término: 30-mayo-2019.

2) Fernández De Miguel Francisco: del Bel Elaine, Dra. Procedencia: Universidad de Sao Paulo. Ribeirao Preto. Brasil. Motivo de la visita: Impartir conferencia: Doxycycline restrains neuroinflammation and confers neuroprotection in Parkinson disease model. Fecha inicio: 27-octubre-2019. Fecha término: 28-octubre-2019.

3) Furlan Magaril Mayra: Martínez Pachec Mónica, Dra. Procedencia: Centro de Ciencias Genómicas. Motivo de la visita: Colaboración. Fecha inicio: 01-marzo-2019.

4) García Sáinz Jesús Adolfo: Medina Bañuelos Luz del Carmen. Procedencia: Universidad Autónoma Metropolitana - Iztapalapa. Motivo de la visita: Estancia-Proyecto en colaboración. Fecha inicio: 01-enero-2019. Fecha término: 31-diciembre-2019.

5) González Halphen Diego: Giraud Marie-France. Procedencia: Institut de Biochimie et Génétique Cellulaires, CN. Motivo de la visita: en el marco de la Cooperación Internacional México-Francia apoyado por el Fondo FONCICYT 2 del CONACyT. Fecha inicio: 21-mayo-2019. Fecha término: 03-junio-2019.

6) Hernández Cruz Arturo: Hernández Guijo Jesús Miguel. Procedencia: Facultad de Medicina, Universidad Autónoma de Madrid. Motivo de la visita: Impartir curso para el posgrado "Modulación de la transmisión sináptica en sistema nervioso central y periférico". Fecha inicio: 06-mayo-2019. Fecha término: 17-mayo-2019.

7) Hernández Cruz Arturo: Montes de Oca Pavel. Procedencia: Unidad de Neurobiología Dinámica, Instituto Nacional de Neurología y Neurocirugía. Motivo de la visita: Estancia de Investigacion. Fecha inicio: 07-enero-2019. Fecha término: 15-diciembre-2020.

8) Peña Díaz Antonio: Calderón Marissa, Dra. Procedencia: FES Iztacala, UNAM. Motivo de la visita: Proyecto en colaboración. Fecha inicio: 01-enero-2019. Fecha término: 31-diciembre-2020.

9) Pérez de la Mora Miguel: Borroto Escuela Dasiel, Dr. Procedencia: Karolinska Institutet. Motivo de la visita: Seminario Extraordinario y taller sobre la técnica del PLA. Fecha inicio: 26-noviembre-2019. Fecha término: 29-noviembre-2019.

10) Tecuapetla Aguilar Fatuel: Rozas Salas Carlos, Dr. Procedencia: Universidad Santiago de Chile. Motivo de la visita: Aprender técnicas de optogenética. Fecha inicio: 01-febrero-2019. Fecha término: 23-febrero-2019.

11) Tecuapetla Aguilar Fatuel: Reyes Mendez Miriam Edith. Procedencia: Universidad de Colima. Motivo de la visita: Aprender técnicas de optogenética. Fecha inicio: 15-agosto-2019. Fecha término: 30-septiembre-2019.

12) Tecuapetla Aguilar Fatuel: Jiménez Mejía Juan Carlos, Dr. Procedencia: FES Iztacala, UNAM. Motivo de la visita: Aprender técnicas de optogenética. Fecha inicio: 01-junio-2019. Fecha término: 30-junio-2019.

13) Velasco Iván: Benvenisty Nissim. Procedencia: Hebrew University, Jerusalem, Israel. Motivo de la visita: Seminario para la Sociedad Mexicana para la Investigación en Células Troncales. Fecha inicio: 30-junio-2019. Fecha término: 03-julio-2019.

14) Velasco Iván: González Pérez Óscar. Procedencia: Universidad de Colima. Motivo de la visita: Impartición del seminario institucional del 31 de mayo de 2019. Fecha inicio: 30-mayo-2019. Fecha término: 31-mayo-2019.

COMISIÓN DICTAMINADORA Y ASUNTOS ACADÉMICO-ADMINISTRATIVOS

La Comisión Dictaminadora del Instituto de Fisiología Celular, está conformada de la siguiente manera:

Por el Rector:

(Consejo Académico del Área de las Ciencias Biológicas y de la Salud).

- Dra. María Elena Teresa Medina-Mora Icaza
- Dr. Enrique Merino Pérez

Por el Consejo Interno:

- Dra. Adela Rodríguez Romero
- Dr. José Víctor Segovia Vila

Por el Colegio del Personal Académico:

- Dr. Lorenzo Patrick Segovia Forcella
- Dr. Hugo Merchant Nancy

Durante el año 2019 la Comisión dictaminó y en su caso opinó sobre los siguientes casos:

PROMOCIONES

Guadalupe Domínguez Macouzet	a Técnico Académico Titular	"C"
Norma Espinosa Sánchez	a Técnico Académico Titular	"C"
José Luis Ramos Balderas	a Técnico Académico Titular	"A"

OBRAS DETERMINADAS

Daniel Osorio Gómez	Investigador Asociado	"C"
C. Leonardo Peraza Reyes	Investigador Asociado	"C"
Román Rossi Pool	Investigador Asociado	"C"
Violeta Gisselle López Huerta	Investigador Asociado	"C"

Jesús Manuel Álvarez López	Técnico Académico Titular	“B”
Luz Lazos Ramírez	Técnico Académico Titular	“B”
Ana Cecilia Rosen Ferlini	Técnico Académico Titular	“B”
Luis Francisco Rodríguez Durán	Técnico Académico Titular	“B”
Beatriz Aguilar Maldonado	Técnico Académico Titular	“A”
Rosario Pérez Molina	Técnico Académico Titular	“A”
Enrique Chávez Jiménez	Técnico Académico Titular	“A”
Arturo Picones Medina	Técnico Académico Titular	“A”
Itzel Escobedo Ávila	Técnico Académico Titular	“A”
Nallely Cano Domínguez	Técnico Académico Titular	“A”
J. Héctor Díaz Osornio	Técnico Académico Asociado	“C”
M. Tonotiuh Figueroa Vanegas	Técnico Académico Asociado	“C”
Augusto César Poot Hernández	Técnico Académico Asociado	“C”
Arriann E. Mendoza Martínez	Técnico Académico Asociado	“C”
Ruth Rincón Heredia	Técnico Académico Asociado	“C”
Mara G. Prior González	Técnico Académico Asociado	“C”
Yoás Saimon Ramírez Graullera	Técnico Académico Asociado	“C”
Ariadna Aparicio Juárez	Técnico Académico Asociado	“C”
Miguel Ramírez Aragón	Técnico Académico Asociado	“C”
Sandra Daniela Rodríguez Montaño	Técnico Académico Asociado	“A”

CONTRATO

Juan Carlos Gómora Martínez	Investigador Titular	“B”
Fatuel Tecuapetla Aguilar	Investigador Titular	“B”
Magdalena Guerra Crespo	Investigador Titular	“A”
Fracisco Sotres Bayón	Investigador Titular	“A”
Luis Bernardo Tovar y Romo	Investigador Titular	“A”
Mayra Furlan Magaril	Investigador Titular	“A”
Paula Licona Limón	Investigador Titular	“A”
Luis Alonso Lemus Sandoval	Investigador Titular	“A”

Adrián Fernando Alvarez	Investigador Asociado	“C”
Sara Luz Morales Lázaro	Investigador Asociado	“C”
Yazmín Ramiro Cortes	Investigador Asociado	“C”
J. Francisco Torres Quiroz	Investigador Asociado	“C”
Myrian Velasco Torres	Investigador Asociado	“C”
Marcelino Arciniega Castro	Investigador Asociado	“C”
Abraham Rosas Arellano	Técnico Académico Titular	“B”
Ana Valeria Martínez Silva	Técnico Académico Titular	“A”
José Luis Ramos Balderas	Técnico Académico Titular	“A”
Josué Orlando Ramírez Jarquín	Técnico Académico Titular	“A”
Ivett Rosas Arciniega	Técnico Académico Asociado	“C”

CONCURSO

Víctor Julián Valdés Rodríguez	Investigador Titular	“A”
Irene Lee Rivera	Técnico Académico Titular	“B”
Beatriz Aguilar Maldonado	Técnico Académico Titular	“A”
Enrique Chávez Jiménez	Técnico Académico Titular	“A”

POSDOCTORALES

Ulises Carrasco Navarro

Mario Alberto Sánchez García

CÁTEDRA CONACyT

Enoch Luis Baltazar

BECARIOS POSDOCTORALES

Tipo de Beca	Número de Becarios Posdoctorales
Beca DGAPA	5
Beca CONACyT	2
Otras Becas	5

1) Aguirre Linares Jesús: Carrasco Navarro Ulises. Procedencia: UAM-Iztapalapa. **Beca DGAPA**. Fecha inicio: 01-septiembre-2019. Fecha término: 31-agosto-2020.

2) Bermúdez Rattoni Federico: Salcedo Tello Ana Pamela. Procedencia: Universidad Nacional Autónoma de México. **Proyecto: OBETEEN.** Fecha inicio: 04-enero-2016. Fecha término: 07-enero-2019.

3) Castro Obregón Susana: Hüttenrauch Melanie. Procedencia: Universidad de Göttingen, Alemania. **Proyecto: Alexander von Humboldt**. Fecha inicio: 01-octubre-2018. Fecha término: 30-septiembre-2020.

4) Del Río Guerra Gabriel: Juárez Arellano Vladimir. Procedencia: Instituto de Fisiología Celular, UNAM. **Proyecto: Alexander von Humboldt**. Fecha inicio: 01-junio-2019. Fecha término: 15-diciembre-2019.

5) Fernández De Miguel Francisco: Moore Corona Sharlen. Procedencia: Universidad Nacional Autónoma de México. **Proyecto: Human Frontiers Science Program**. Fecha inicio: 01-enero-2019. Fecha término: 31-octubre-2019.

6) González Halphen Diego: García Rincón Juan. Procedencia: Instituto de Biotecnología, UNAM. **Beca DGAPA**. Fecha inicio: 01-septimbre-2017. Fecha término: 31-agosto-2019.

7) Hiriart Urdanivia Marcia: Sánchez Zamora Yuriko Itzel. Procedencia: Doctorado Ciencias Biomédicas, Iztacala. **Beca DGAPA**. Fecha inicio: 01-febrero-2018. Fecha término: 31-enero-2020.

8) Licona Limón Paula: Flores Alvarez Luis José. Procedencia: Universidad Michoacana. **Beca CONACyT.** Fecha inicio: 05-agosto-2019. Fecha término: 05-agosto-2021.

9) Macías Silva Marina: Ortega Domínguez Bibiana. Procedencia: Facultad de Quimica, UNAM. **Proyecto: CONACyT-ANR.** Fecha inicio: 01-agosto-2018. Fecha término: 31-enero-2019.

10) Massieu Trigo Lourdes: Rivero Segura Nadia Alejandra. Procedencia: Facultad de Química, UNAM. **Beca DGAPA**. Fecha de inicio: 01-septiembre-2018. Fecha de término: 31-agosto-2019.

11) Tapia Ibarguengoytia Ricardo: Ramirez Jarquin Uri Nimrod. Procedencia: Scripps Institute, Florida. **Proyecto: Posdoctoral asociado al proyecto.** Fecha inicio: 01-enero-2019. Fecha término: 31-diciembre-2019.

12) Tovar y Romo Luis Bernardo: Santana Martínez Ricardo Alberto. Procedencia: Instituto Nacional de Neurología y Neurocirugía “Manuel Velasco Suárez”. **Beca DGAPA**. Fecha inicio: 01-marzo-2019. Fecha término: 28-febrero-2021.

PERSONAL ADMINISTRATIVO

Dirección
Dominga Vera García, Asistente Ejecutivo
Gabriela Valdés Silva, Asistente Ejecutivo
Ubaldo Rodríguez Lagunes, Oficial de Transporte Especializado

Secretaría Académica
Diana Osorio Icaza, Asistente Ejecutivo

Secretaría Administrativa
L.A.E. María del Pilar Martínez Martínez, Secretaria Administrativa
Laura Itzel Méndez Guerrero, Asistente Ejecutivo

Departamento de Personal
L.A.I. María del Carmen Ruiz Valderrábano, Jefe de Departamento
Nancy Lizette Islas Vargas, Asistente Ejecutivo
Lizette Monserrat Saavedra Martínez, Asistente Ejecutivo

Departamentos de Biología Celular y Desarrollo, Genética Molecular y Bioquímica y Biología Estructural
María del Rosario Villaseñor Ávila, Asistente Ejecutivo
Gabriela Valdés Silva, Asistente Ejecutivo
María del Rocío Romualdo Martínez, Asistente Ejecutivo

Departamentos de Neurodesarrollo y Fisiología, Neurociencia Cognitiva y Neuropatología Molecular
Olivia Angélica Farfán Osornio, Secretario Bilingüe
Arleth Gómez Vásquez, Asistente Ejecutivo
Miriam Morales Gómez, Secretario

Coordinación de Enseñanza
Sara Elena Méndez Ibañez, Asistente de Procesos

Departamento de Control Presupuestal
Ángel Cedillo Hernández, Jefe de Departamento
Sabina Rojas Escandón, Secretario
Erika Gisela Vázquez Castro, Auxiliar de Contabilidad

Departamento de Ingresos Extraordinarios
Lic. Claudia Ivette Islas Vargas, Jefe de Departamento
Lina Arreguín Guerrero, Jefe de Sección
Miguel Angel Reyes Montoro, Auxiliar de Contabilidad
Francisco Tomás Márquez Escalona, Secretario

Departamento de Bienes y Suministros
Ing. Mario Arredondo Rivera, Encargado del Despacho del Depto. De Bienes y Suministros
Héctor Antonio Pineda Balcazar, Jefe de Área
Marisela Almanza Villagomez, Secretario Bilingüe
Alfredo Octaviano Martínez, Secretario
María Lidia Sánchez Alpizar, Secretario
Beatriz Fragoso Álvarez, Secretario
Carlos Alberto Hernández Valadez, Oficial de Servicios Administrativo
Virginia Rivera Alvarado, Oficial de Servicios Administrativos

Departamento de Servicios Generales
Ing. Armando Rosalio Canto Canto, Jefe de Departamento
Maria del Carmen Pérez Hernández, Asistente Ejecutivo
Fanny García Guerrero, Secretario
Adriana Camacho Bandera, Secretario
Luis Fernando Molina Martínez, Jefe de Taller
Rocío Arreguín Guerrero, Jefe de Sección
Horacio Cortés Sánchez, Oficial de Servicios Administrativos
José Luis Garduño Garduño, Oficial de Transporte Especializado
Bernardo Castillo López, Oficial de Transporte Especializado
Fabián Domínguez García, Oficial de Transporte

Oficina de DGAPA
Pablo Montiel González, Jefe de Área
Irma Aracelí Santos Cueto, Jefe de Oficina
Jasmín Guerrero Arelio, Oficial de Servicios Administrativos
Domitila Ramírez Rojas, Auxiliar de Contabilidad

Biblioteca
Nadia Brisa Robles Vidal, Bibliotecario
Javier Antonio Robles Durán, Bibliotecario
Marisela Buitrón Cruz, Secretario

Almacén
Irene Rios Castro, Jefe de Oficina
María del Rosario Aguilar Oliver, Secretario
Sergio Méndez Serna, Auxiliar de Intendencia
Abril Jasso Ruiz, Almacenista
Jorge Guerrero Morales, Oficial de Servicios Administrativos

Bioterio
Miriam Pedraza Alanís, Secretario
Alma Rosa Solis Ibarra, Laboratorista
Liliana Bolaños Granda, Laboratorista
Lino Méndez Laso, Laboratorista
Miguel Hernández Cedillo, Laboratorista
Alejandro Monroy Badillo, Laboratorista
Miguel Ángel Monroy Badillo, Auxiliar de Laboratorio
Jesús Moya Jaime, Auxiliar de Laboratorio
José Carlos Lugo Márquez, Auxiliar de Laboratorio
Humberto Quintero Cortés, Laboratorista
Hugo Zenteno Alba, Auxiliar de Laboratorio
José René Flores Rodríguez, Auxiliar de Laboratorio
Erika Cazandra Ávila García, Auxiliar de Intendencia

Laboratoristas
Héctor Zenteno Alba
María Gianelli Cortés González
Marina Cristóbal Ortiz
José Fabián Márquez Escalona
Víctor Manuel Méndez Ramos
Concepción Núñez Vázquez
Patricia Hernández García
Mario Zamora Jiménez
María José Zamora Jiménez
Alejandro Flores Rodríguez
Sergio Méndez Franco
Juan Carlos Molina Martínez
Félix Sierra Ramírez

Auxiliares de Laboratorio
Adrián Alvarado Martínez
Cristina Jardínez Godínez
Rosa María Arelio Nápoles
César Alejandro Bolaños Vidal

La distribución de equidad de género entre el personal administrativo y de confianza se representa en la siguiente gráfica.

Distribución del Personal Administrativo y de Confianza por Género

	ADMINISTRATIVO	CONFIANZA	FUNCIONARIO
MUJER	65	11	3
HOMBRE	64	0	5

FORMACIÓN DE RECURSOS HUMANOS

Estudiantes

Los estudiantes son una parte fundamental en las actividades académicas y de investigación en el Instituto. Son colaboradores de los diversos proyectos de investigación que se desarrollan. Durante 2019, el IFC recibió un total de 508 estudiantes de los cuales 15 estudiantes son de Taller, 10 estudiantes de LIBB estuvieron de rotación en laboratorios, 31 alumnos relizaron su estancia de investigación en alguno de nuestros laboratorios, 65 tesistas de Licenciatura, 81 alumnos inscritos a la Licenciatura en Neurociencias, 120 estudiantes de Maestría en Ciencias Bioquímicas, 9 estudiantes de Maestría en Ciencias Biológicas, 86 alumnos son de Doctorado en Ciencias Biomédicas, 76 estudiantes de Doctorado en Ciencias Bioquímicas, 9 estudiantes de Doctorado en Ciencias Biológicas y 3 estudiantes de otro programa de Doctorado y Maestría, respectivamente.

15	• Alumnos de taller
10	• Alumnos de rotación LIBB
31	• Alumnos de estancia de investigación
65	• Alumnos tesistas de Licenciatura
81	• Licenciatura en Neurociencia
120	• Alumnos de Maestría en Ciencias Bioquímicas
9	• Alumnos de Maestría en Ciencias Biológicas
86	• Alumnos de Doctorado en Ciencias Biomédicas
76	• Alumnos de Doctorado en Ciencias Bioquímicas
9	• Alumnos de Doctorado en Ciencias Biológicas

Graduados

Durante 2019 se graduaron en total 75 estudiantes, 14 estudiantes de Licenciatura, 29 estudiantes de Maestría en Ciencias Bioquímicas, 5 de ellos por defensa de proyecto, 7 estudiantes de Maestría en Ciencias Biológicas, 12 estudiantes de Doctorado en Ciencias Biomédicas, 11 estudiantes de Doctorado en Ciencias Bioquímicas y 2 estudiantes de Doctorado en Ciencias Biológicas.

DOCENCIA

Cursos Impartidos

La docencia es una de las actividades sustanciales del IFC porque contribuye al desarrollo de recursos humanos. El personal académico del Instituto ha tenido un gran desempeño en la impartición de diversos cursos de Posgrado y Licenciatura, dentro y fuera de la UNAM.

Debido a la participación del IFC en los diversos programas de Maestría y Doctorado y a la colaboración de los académicos con otras dependencias de la UNAM, se impartieron cursos en la Facultad de Ciencias, Facultad de Medicina y la Facultad de Ingeniería principalmente, también se dieron cursos en la Facultad de Psicología, en el Centro de Ciencias Genómicas, en el Instituto de Neurobiología y en el Instituto de Investigaciones Biomédicas.

De igual manera se impartieron cursos fuera de la UNAM, en otras instituciones educativas y universidades como la Universitat Autónoma de Barcelona, el CINVESTAV del IPN, por mencionar algunas.

El total de cursos impartidos durante el 2019 suman 136, 117 fueron impartidos en diversas dependencias de la UNAM, 48 cursos de nivel posgrado y 69 de licenciatura. Dentro del Instituto de Fisiología Celular se impartieron 39 cursos de los 117 dictados dentro de la UNAM. Los que fueron impartidos fuera de la UNAM sumaron un total de 19, de los cuales 15 fueron de posgrado y 4 de licenciatura.

REVISIÓN DE ACTIVIDADES ACADÉMICAS DE DOCTORADO

- **Aguilar Roblero Raúl**
  Estudiante: Armida Miranda Riestra.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Artículo de revisión: La melatonina como factor de diferenciación neuronal.

- **Castro Obregón Susana**
  Estudiante: José Rolando Lara Rodarte.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Use of inducible expression systems in embryonic stem cells for the expresión of neurorophic factors.

- **Funes Argüello Soledad**
  Estudiante: Carlos Alberto Ayhllon Osorio.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Artículo de revisión: AZT, a double-edged sword: A summary of its intracellular repercussions.

- **González Pedrajo Bertha**
  Estudiante: Greta Isabel Reynoso Cereceda.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: A look inside the bioreactor: Molecular response of *E. coli* productive cells.

- **González Pedrajo Bertha**
  Estudiante: Nelly Araceli Aburto Rodríguez.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Quorum sensing and type III secretion system inhibitors as an alternative therapy to treat drug resistant bacterial infections.

- **Massieu Trigo Lourdes**
  Estudiante: Karina Sánchez Alegría.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Effects of saturated fatty acids on brain function.

- **Peraza Reyes Leonardo**
  Estudiante: Carlos Alberto Ayhllon Osorio.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: AZT, a double-edged sword: A summary of its intracellular repercussions.

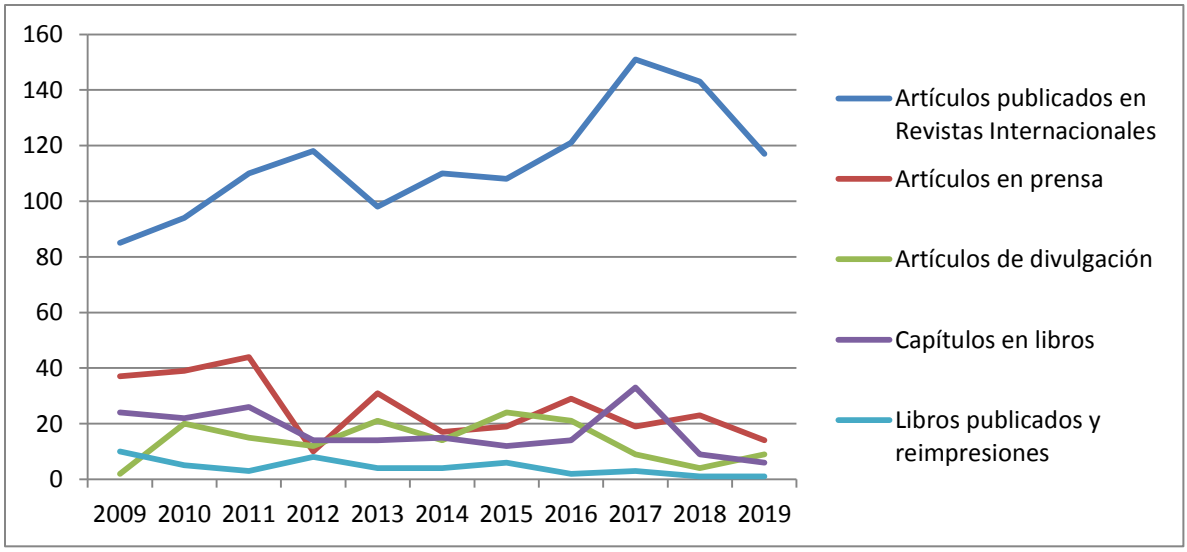
- **Ramiro Cortés Yazmín**
  Estudiante: Ana Silvia Báez Cordero.
  Trabajo revisado: Tesis de maestria: Integración de la vía directa e indirecta en la actividad de la sustancia nigra reticulata de los ganglios basales y su modulación por canabinoides.

- **Ramiro Cortés Yazmín**
  Estudiante: Daniel Pérez Torres.
  Trabajo revisado: Tesis de maestria: Evaluación de la actividad intrínseca de las células del núcleo ventro-basal talámico en ratas cegadas al nacimiento.

- **Ramiro Cortés Yazmín**
  Estudiante: Mildred Salgado Ménez.
  Trabajo revisado: Tesis de maestria: Modulación catecolaminérgica en evocación y actualización de la memoria espacial.

- **Ramiro Cortés Yazmín**
  Estudiante: Esteban Urrieta Chávez.
  Trabajo revisado: Tesis de maestria: Regulación metaplástica de la depresión de largo plazo in vivo en la corteza insular debida al condicionamiento.

- **Tovar y Romo Luis Bernardo**
  Estudiante: Jorge Luis Ochoa.
  Programa: Posgrado en Ciencias Biomédicas.
  Trabajo revisado: Receptores de citocinas inflamatorias sobre sinápsis hipocampales.



PRODUCCIÓN ACADÉMICA

El crecimiento de la planta académica y el desempeño del personal académico han tenido como resultado una constante productividad científica, obteniendo en el 2019 un total de 117 artículos indizados con índice de impacto promedio de 5.02, lo que representa 2.05 artículos por grupo de investigación.

Además, 14 artículos se encuentran en prensa, se publicaron 9 artículos de divulgación, 6 capítulos en libros, 8 capítulos en prensa, 1 libro publicado y reimpreso, 6 revistas nacionales y 1 Patente Nacional concluida son parte del resultado de la investigación en el IFC en 2019.

Artículos Publicados en Revistas Internacionales

1) Acosta Montaño, P; Ibarra López, E; Mas Oliva, J; Delgado Coello, B; Rivero, I; Alatorre Meda, M; Aguilera, J; Rodríguez Velázquez, E; Guevara Olaya, E; García González, V. (2019). Fatty acid and lipopolysaccharie effect on beta cells proteostasis and its impacto n insulin secretion. *Cell*. **8**: 884. **FI: 36.216; Q1**.

2) Akinaga, J; García Sáinz, J; Pupo, S. A. (2019). Updates in the function and regulation of α1 –adrenoceptors. *Brit. J. Pharmacol*. **176**: 2343-2357. **FI: 6.583; Q1**.

3) Almanza, A; Segura Chama, P; León Olea, M; Luis, E; Garduño Gutiérrez, R; Mercado Reyes, J; Simón Arceo, K; Coffeen, U; Hernández Cruz, A; Pellicer, F; Mercado, F. (2019). Cellular mechanism for specific mechanical antinociception by D2-like receptor at the spinal cord level. *Neuroscience*. **417**: 81-94. **FI: 3.244; Q2**.

4) Amezcua Vesely, M; Pallis, P; Bielecki, P; Low, J; Zhao, J; Harman, C; Kroehling, L; Jackson, R; Bailis, W; Licona Limón, P; Xu, H; Iijima, N; Pillai, P; Kaplan, D; Weaver, C; Kluger, Y; Kowalczyk, M; Iwasaki, A; Pereira, J; Esplugues, E; Gagliani, N; Flavell, R. (2019). Effector TH17 cells give rise to long-lived TRM cells that are essential for an immediate response against bacterial infection. *Cell*. **178**: 1176-1188.el5. **FI: 36.216; Q1**.

5) Aparicio Juárez, A; Duhne, M; Lara González, E; Ávila Cascajares, F; Calderón, V; Galarraga, E; Bargas, J. (2019). Cortical stimulation relieves parkinsonian pathological activity *in vitro*. *European Journal and Neuroscience*. **49**: 834-848. **FI: 2.832; Q2**.

6) Arroyo Pérez, E. E; González Cerón, G; Soberón Chávez, G; Georgellis, D; Servin Gonzalez, L. (2019). A novel two-component system, encoded by the sco5282/sco5283 genes, affects *streptomyces coelicolor* morphology in liquid culture. *Frontiers in Micobiology*. **10**: 1568. **FI: 4.259; Q1**.

7) Arzate, D; Guerra Crespo, M; Covarrubias, L. (2019). Induction of typical and atypical neurogenesis in the adult substantia nigra after mouse embryonic stem cells transplantation. *Neuroscience*. **408**: 308-326. **FI: 3.244; Q2**.

8) Azuara Medina, P. M; Sandoval Duarte, A. M; Morales Lázaro, S. L; Modragón González, R; Vélez Aguilera, G; Gómez López, J. D; Jiménez Gutiérrez, G. E; Tiburcio Félix, R; Martínez Vieyra, I; Suárez Sánchez, R; Längst, G; Javier Magaña, J; Winder, S. J; Ortega, A; Ramos Perlingeiro, R. C; Jacobs, L. A; Cisneros, B. (2019). The intracellular domain of β-dystroglycan mediates the nucleolar stress response by suppressing UBF transcriptional activity. *Cell Death & Disease.* **10**(196). **FI: 5.959; Q1**.

9) Bahena Alvarez, D; Rincón Heredia, R; Millán Aldaco, D; Fiordelisio, T; Hernández Cruz, A. (2019). Calcium signaling and expression of voltage-gated calcium channels in the mouse ovary throughout the estrous cycle. *Biology of reproduction*. **100**: 1018-1034. **FI: 2.96; Q1**.

10) Barbosa Nascimento Viana, J; Alcántara Hernández, R; Oliveira Barros, E; Castello Branco, L. A; Feijó, P. R; Soares Romeiro, L. A; Nasciutti, L. E; Noël, F; García Sáinz, J. A; Martins Silva, C. L. (2019). The alpha 1-adrenoceptor-mediated human hyperplastic prostate cells proliferation is impaired by EGF receptor inhibition. *Life Sci*. **239**: 117048. **FI: 3.448; Q1**.

11) Barriga Montoya, C; de la O Martínez, A; Picones, A; Hernández Cruz, A; Fuentes Pardo, B; Gómez Lagunas, F. (2019). Desensitization and recovery of crayfish photoreceptors upon delivery of a light stimulus. *J. Vis. Exp*. **153**: e56258. **FI: 1.108; Q2**.

12) Bastián Eugenio, C; Bohórquez Hernández, A; Pacheco, J; Sampieri, A; Asanov, A; Ocelotl Oviedo, J; Guerrero, A; Darszon, A; Vaca, L. (2019). Heterologous calcium-dependent inactivation of orai1 by neighboring TRPV1 channels modulates cell migration and wound healing. *Communications Biology*. **2**: 88. **FI: 2.5; Q1**.

13) Binh Nguyen, M; Valdes, V. J; Cohen, I; Pothula, V; Zhao, D; Zheng, D; Ezhkova, E. (2019). Dissection of Merkel cell formation in hairy and glabrous skin reveals a common requirement for FGFR2-mediated signalling. *Experimetal Dermatology*. **28**: 374-382. **FI: 2.868; Q1**.

14) Borroto Escuela, D; Narvaez, M; Zannoni, M; Contri, C; Crespo Ramírez, M; di Palma, M; Ambrogini, P; Brito, I; Pita Rodríguez, M; Valladolid Acebes, I; de la Mora, M; Fuxe, K. (2019). Isolation and detection of G protein-coupled receptor (GPCR) heteroreceptor complexes in rat brain synaptosomal preparation using a combined brain subcellular fractionation/co-immunoprecipitarion (Co-IP) procedures. Co-Immunoprecipitation Methods for Brain Tissue. *Neuromethods*. **144**: 123-135. **FI: 3.00; Q3**.

15) Cano Domínguez, N; Bowman, B; Peraza Reyes, L; Aguirre, J. (2019). Neurospora crassa NADPH oxidase NOX-1 is localized in the vacuolar system and the plasma membrane. *Frontiers in Microbiology*. **10**: 1825. **FI: 4.259; Q1**.

16) Carbone, E; Borges, R; Eiden, L. E; Garcia, A. G; Hernández Cruz, A. (2019). Chromaffin cells of the adrenal medulla: physiology, pharmacology, and disease*. Comprehensive. Physiol*. **9**: 1443-1502. **FI: 6.246; Q1**.

17) Cárdenas Rivera, A; Campero Romero, A. N; Heras Romero, Y; Penagos Puig, A; Rincón Heredia, R; Tovar y Romo, L. B. (2019). Early post-stroke activation of vascular endothelial growth factor receptor 2 hinders the receptor 1-dependent neuroprotection afforded by the endogenous ligand. *Front. Cell. Neurosci*. **13**: 1-15. **FI: 3.900; Q2**.

18) Carmona Rosas, G; Alcántara Hernández, R; Hernández Espinosa, D. A. (2019). The role of beta-arrestins in G protein-coupled receptor heterologous desensitization: A brief story. *Methods Cell Biol*. **149**: 195-204. **FI: 1.698; Q2**.

19) Carmona Rosas, G; Hernández Espinosa, D. A; Alcántara Hernández, R; Alfonzo Méndez, M. A; García Sainz, J. A. (2019). Distinct phosphorylation sites/clusters in the carboxyl terminus regulate α1D-adrenergic receptor subcellular localization and signaling. *Cellular Signalling*. **53**: 374-389. **FI: 3.388; Q2**.

20) Carranza García, E; Navarro, R. E. (2019). Apoptosis contributes to protect germ cells from the oogenic germline starvation response but is not essential for the gonad shrinking or recovery observed during adult reproductive diapause in *C. elegans*. *PLoS one*. **14**: e0218265. **FI: 2.776; Q1**.

21) Castillo, X; Castro Obregón, S; Gutiérrez Becker, B; Gutiérrez Ospina, G; Karalis, N; Khalil, A. A; López Noguerola, J. 84) Olivas Aguirre, M; Torres López, L; Valle Reyes, J. S; Hernández Cruz, A; Pottosin, I; Dobrovinskaya, O. (2019). Cannabidiol directly targets mitochondria and disturbs calcium homeostasis in acute lymphoblastic leukemia. *Cell Death and Disease*. **10**: 779. **FI: 5.910; Q1**.

85) Osorio Gómez, D; Bermúdez Rattoni, F; Guzmán Ramos, K. (2019). Artificial taste avoidance memory induced by coactivation of NMDA and β-adrenergic receptors in the amygdala. *Behav. Brain Res*. **376**: 112193. **FI: 2.77; Q1**.

86) Osorio Gómez, D; Saldivar Mares, K. S; Perera López, A; McGaugh, J. L; Bermúdez Rattoni, F. (2019). Early memory consolidation window enables drugs induced state-dependent memory. *Neuropharmacology*. **146**: 84-94. **FI: 4.367; Q1**.

87) Pérez Estrada, J. R; Hernández García, D; Leyva Castro, F; Ramos León, J; Cuevas Benítez, O; Díaz Muñoz, M; Castro Obregón, S; Ramírez Solís, R; García, C; Covarrubias, L. (2019). Reduced lifespan of mice lacking catalase correlates with altered lipid metabolism without oxidative damage or premature aging. *Free Radical Biology and Medicine*. **135**: 102-115. **FI: 5.657; Q1**.

88) Pérez González, C; Domenzain, C; Poggio, S; González Halphen, D; Dreyfus, G; Camarena, L. (2019). Characterization of FlgP, an essential protein form flagellar assembly in *Rhodobacter sphaeroides. Journal of Bacteriology*. **201**: 1-16. **FI: 3.130; Q1**.

89) Piatkevich, K. D; Bensussen, S; Tseng, H; Shroff, S; Lopez Huerta, V. G; Park, D; Jung, E; Shemesh, O; Straub, C; Gritton, H; Romano, M; Costa, E; Sabatini, B; Fu, Z; Boyden, E; Han, X. (2019). Population imaging of neural activity in awake behaving mice. *Nature*. **574**: 413-417. **FI: 24.360; Q1**.

90) Polo Castillo, L. E; Villavicencio, M; Ramírez Lugo, L; Illescas Huerta, E; Gil Moreno, M; Ruiz Huerta, L; Gutiérrez, R; Sotres Bayón, F; Caballero Ruiz, A. (2019). Reimplantable microdrive for long-term chronic extracellular recordings in freely moving rats. *Frontiers in Neuroscience*. **13**: 128. **FI: 3.810; Q1**.

91) Rivero Segura, N. A; Coronado Mares, Ma. I; Rincón Heredia, R; Pérez Torres, I; Montiel, T; Pavón, N; Cabrera Reyes, E. A; Massieu, L; Cerbón, M. (2019). Prolactin prevents miyochondrial dysfunction induced by glutamate excitotoxicity in hippocampal neurons. *Neurosciences Letters*. **701**: 58-64. **FI: 2.274; Q1**.

92) Rodríguez Bolaños, M; Pérez Montfort, R. (2019). Medical and veterinary importance of the moonlighting functions of triosephosphate isomerase. *Current Protein and Peptide Science*. **20**: 304-315. **FI: 1.470; Q2**.

93) Roig Puiggros, S; Vigouroux, R. J; Beckman, D; Bocai, N. I; Chiou, B; Davimes, J; Gomez, G; Grassi, S; Hoque, A; Karikari, T. K; Kiffer, F; Lopez, M; Lunghi, G; Mazengenya, P; Meier, S; Olguín Albuerne, M; Oliveira, M. M; Paraíso Luna, J; Pradhan, J; Radiske, A; Ramos Hryb, A. B; Ribeiro, M. C; Schellino, R; Selles, M. C; Singh, S; Theotokis, P; Chédotal, A. (2019). Construction and reconstruction of brain circuits: normal and pathological axon guidance. *J. Neurochem*. **153**: 10-32. **FI: 4.830; Q1**.

94) Rossi Pool, R; Romo, R. (2019). Low dimensionality, high robustness in neural population dynamics. *Neuron*. **103**: 177-179. **FI: 14.403; Q1**.

95) Rossi Pool, R; Zizumbo, J; Alvarez, M; Vergara, J; Zainos, A; Romo, R. (2019). Temporal signals underlying a cognitive process in the dorsal premotor cortex. *Proc. Natl. Acad. Sci. USA*. **116**: 7523-7532. **FI: 9.350; Q1**.

96) Rubalcava Gracia, D; García Rincón, J; Pérez Montfort, R; Hamel, P. P; González Halphen, D. (2019). Key within-membrane residues and precursor dosage impact the allotopic expression of yeast subunit II of cytochrome c oxidase. *Mol. Biol Cell*. **30**: 2358-2366. **FI: 3.905; Q1**.

97) Saavedra Montañez, M; Vaca, L; Ramírez Mendoza, H; Gaitán Peredo, C; Bautista Martínez, R; Segura Velázquez, R; Cervantes Torres, J; Sánchez Betancourt, J. I. (2019). Identification and genomic characterization of influenza viruses with different origin in Mexican pigs. *Transboundary and Emerging Diseases*. **66**: 186-194. **FI: 3.554; Q1**.

98) Saldaña Meyer, R; Rodriguez Hernaez, J; Escobar, T; Nishana, M; Jacome López, K; Nora, E. P; Bruneau, B. G; Tsirigos, A; Furlan Magaril, M; Skok, J; Reinberg, D. (2019). RNA interactions are essential for CTCF-mediated genome organization. *Mol. Cell*. **76**: 412-422.e5. **FI: 14.548; Q1**.

99) Sánchez Sandoval, A. L; Gomora, J. C. (2019). Contribution of voltaje-gated sodium cannel beta-subunits to cervical cancer cells metastatic behavior. *Cancer Cell International*. **19**: 1-13. **FI: 3.630; Q2**.

100) Serratos, I. N; López Macay, A; Castellanos, P; Córdoba Herrera, J. G; Pérez Montfort, R; Cabrera, N; Arechavaleta Velasco, F; Domínguez López, P; Santamaría, A. (2019). Co-localization of the receptor for advanced glycation end products (RAGE) with S100 calcium-binding protein B (S100B) in human umbilical vein endothelial. *Journal of the Mexican Chemical Society*. **63**: 25-32. **FI: 0.490; Q3**.

101) Sharma, M; Ramírez Jarquín, U. N; Rivera, O; Kazantzis, M; Eshraghi, M; Shahani, N; Sharma, V; Tapia, R; Subramaniam, S. (2019). Rhes, a striatal-enriched protein, promotes mitophagy via nix. *Proc. Natl. Acad. Sci. USA*. **116**: 23760-23771. **FI: 9.350; Q1**.

102) Soto Aceves, M. P; Cocotl Yañez, M; Merino, E; Castillo Juárez, I; Cortés López, H; González Pedrajo, B; Díaz Guerrero, M; Servín González, L; Soberón Chávez, G. (2019). Inactivation of the quorum-sensing transcriptional regulators LasR OR RhlR does not suppress the expression of virulence factors and the virulence of pseudomonas aeruginosa PAO1. *Microbiology* (Reading, England). **165**: 425-432. **FI: 0.990; Q2**.

103) Tapia Vieyra, J. V; Mas Oliva, J. (2019). Descubrimiento de la proteína reguladora de apoptosis 2 como determinante en la muerte de células tumorales. *Gac. Med. Mex*. **155**: 546-553. **FI: 0.290; Q4**.

104) Tapia, D; Suárez, P; Arias García, M. A; Garcia Vilchis, B; Serrano Reyes, M; Bargas, J; Galarraga, E. (2019). Localization of chloride co-transporters in striatal neurons. *Neuroreport*. **30**: 457-462. **FI: 1.200**.

105) Tauste Campo, A; Vázquez, Y; Alvarez, M; Zainos, A; Rossi Pool, R; Deco, G; Romo, R. (2019). Feed-forward information and zero-lag synchronization in the sensory thalamocortical circuit are modulated during stimulus perception. *Natl. Acad. Sci. USA*. **116**: 7513-7522. **FI: 9.350; Q1**.

106) Tecalco Cruz, A. C; Cortés González, C. C; Cruz Ramos, E; Ramírez Jarquín, J. O; Romero Mandujano, A. K; Sosa Garrocho, M. (2019). Interplay between interferon-stimulated gene 15/ISGYlation and interferon gamma signaling in breast cancer cell. *Cellular Signalling*. **54**: 91-101. **FI: 3.388; Q2**.

107) Tecalco Cruz, A. C; Ramírez Jarquín, J. O; Cruz Ramos, E. (2019). Estrogen receptor alpha and its ubiquitination in breast cancer cells. *Current Drug Targets*. **20**: 690-704. **FI: 2.290; Q2**.

108) Torres López, L; Maycotte, P; Liñán Rico, A; Liñán Rico, L; Donis Maturano, L; Delgado Enciso, I; Meza Robles, C; Vásquez Jiménez, C; Hernández Cruz, A; Dobrovinskaya, O. (2019). Tamoxifen induces toxicity, causes autophagy, and partially reverses dexamethasone resistance in Jurkat T cells. *Journal of Leukocyte Biology*. **105**: 983-998. **FI: 4.012; Q1**.

109) Trastoy Pena, R; Blasco, L; Ambroa, A; González Pedrajo, B; Fernández García, L; López, M; Bleriot, I; Bou, G; García Contreras, R; Wood, T. K; Tomas, M. (2019). Relationship between quorum sensing and secretion systems. *Frontiers in Microbiology*. **10**: 1100. **FI: 4.190; Q1**.

110) Uribe Alvarez, C; Chiquete Félix, N; Morales García, L; Bohórquez Hernández, A; Delgado Buenrostro, N. L; Vaca, L; Peña, A; Uribe Carvajal, S. (2019). *Wolbachia pipientis* grows in *Saccharomyces cerevisiae* evoking early death of the host and deregulation of mitochondrial metabolism. *MicrobiologyOpen*. **8**: e00675. **FI: 2.710; Q2**.

111) Valencia Sánchez, S; Nava Castro, K. E; Palacios Arreola, M. I; Prospéro García, O; Morales Montor, J; Drucker Colín, R. (2019). Chronic exercise modulates the cellular immunity and its cannabinoid receptors expression. *PLoS ONE*. **14**: e0220542. **FI: 2.870; Q1**.

112) Vargas Romero, F; González Barrios, R; Guerra Calderas, L; Escobedo Avila, I; Cortes Pérez, D; López Ornelas, A; Rocha, L; Soto Reyes, E; Velasco, I. (2019). Histamine modulates midbrain dopamine neuron differentiation though the regulation of epigenetic marks. *Frontiers in Cellular Neurociences*. **13**: 215. **FI: 3.910**.

113) Villalobos García, D; Hernández Muñoz, R. (2019). Lactate-stimulated ethanol oxidation: Revisiting an old hypothesis. *Biochemical Pharmacology*. **164**: 283-288. **FI: 4.825; Q1**.

114) Villegas Comonfort, S; Guzmán Silva, A; Romero Ávila, M. T; Takei, Y; Tsujimoto, G; Hirasawa, A; García Sáinz, J. A. (2019). Receptor tyrosyne kinase activation induced free fatty acid 4 receptor phosphorylation, beta-arrestin interaction, and internalization. *European Journal of Pharmacology*. **855**: 267-275. **FI: 3.17; Q1**.

115) Zarate Romero, A; Stojanoff, V; Cohen, A. E; Hansberg, W; Rudiño Piñera, E. (2019). X-ray driven reductionof Cpd I of Catalase-3 from N. *crassa* reveals differential sensitivity of actives sites and formation of ferrous state. *Archives of Biochemistry and Biophysics*. **666**: 107-115. **FI: 3.559; Q1**.

116) Zepeda, N; Copitin, N; Chávez, J. L; García, F; Jaimes Miranda, F; Rincón Heredia, R; Paredes, R; Solano, S; Fernández, A. M; Molinari, J. L. (2019). Hippocampal sclerosis induced in mice by a *Taenia crassiceps* metacestode factor. *J. Helminthol*. **93**: 690-696. **FI: 1.300; Q2**.

117) Zepeda Cervantes, J; Cruz Reséndiz, A; Sampieri, A; Carreón Nápoles, R; Sánchez Betancourt, J. I; Vaca, L. (2019). Incorporation of ORF2 from porcine circovirus type 2 (PCV2) into genetically encoded nanoparticles as a novel vaccine using a self-aggregating peptide. *Vaccine*. **37**: 1928-1937. **FI: 3.269; Q1**.

INSTITUCION	MONTO	ENLACE	CONGRESO/ MOTIVO	FECHA
Sociedad Mexicana de Bioquímica	$35,000.00	Dra. Susana Castro Obregón	Tercer Congreso Nacional de la Rama de Neurobiología	22 al 25 de septiembre
Asociación Mexicana de Microbiología	$20,000.00	Dra. Bertha González Pedrajo	XLI y VI Congresos Nacionales	27 al 31 de octubre de 2019
Sociedad Mexicana de Bioquímica	$30,000.00	Dr. Félix Recillas Targa	Transducción de señales	4 al 7 de noviembre de 2019
Sociedad Mexicana de Bioquímica	$20,000.00	Dr. Félix Recillas Targa	Rama radicales libres y especies reactivas del oxigeno	9 al 11 de septiembre de 2019
Sociedad Mexicana de Bioquímica	$10,000.00	Dra. Soledad Funes Argüello	XVIII Congreso Nacional de la rama de Bioquímica y Biología Molecular de Plantas	28 al 31 de octubre de 2019
Sociedad Mexicana para la Investigación de Células Troncales	$25,000.00	Dr. Iván Velasco Velázquez	5th International meeting on stem cells and regenerative medicine	14 de agosto de 2019 21 al 23 de octubre de 2019
TOTAL	$140,000.00			

PONENCIAS

El personal académico del IFC asistió a 15 Congresos Nacionales con 35 participaciones con ponencias y 78 presentaciones en forma de cartel; en 35 Congresos Internacionales donde se presentaron 39 carteles y 24 ponencias. Además, 20 participaciones con ponencia en 16 simposios internacionales y 7 presentaciones de carteles. 11 Simposios Nacionales donde se tuvieron 15 participaciones en ponencias.

Se impartieron 30 Conferencias Nacionales y 5 Internacionales, 30 seminarios dentro de la UNAM y 22 seminarios fuera de ella.

CONGRESOS NACIONALES	35 Participaciones con ponencia 78 Participaciones con cartel
2nd Epigenomics Meeting, 2019. Epigenetic Regulation in Human Disease.	
CEMUS XIV. Congreso de estudiantes de medicina del noroeste. Neurociencias.	
III Neurobiology Meeting of the Mexican Society for Biochemistry. SMB.	
LXII Congreso Nacional de la Sociedad Mexicana de Ciencias Fisiológicas A.C.	
Taller Multidisciplinario de Redes. Taller de análisis de señales neurofisiológicas.	
XLI Congreso Nacional de Microbiología y VI Congreso de Bioquímica y Biología Molecular de Bacterias.	
VII Congreso de Especies Reactivas del Oxígeno en Biología y Medicina SMB.	
VII Congreso Nacional de la Rama de Transducción de Señales de la Sociedad Mexicana de Bioquímica.	
XIII Congreso de Posgrado en Psicología.	
XIII Congreso Nacional de Biología Molecular y Celular de Hongos.	
XXI Congreso de Bioenergética y Biomembranas de la SMB.	
XXVII Congreso Mexicano de Psicología. Sociedad Mexicana de Psicología y el Instituto de Neurociencias de la Universidad de Guadalajara.	
XVIII Congreso Nacional de Biotecnología y Bioingeniería.	
XXXIV Reunión Anual de Investigación. Instituto Nacional de Neurología y Neurocirugía "Manuel Velasco Suárez" (INNN).	
VI Latin American Protein Society Meeting (LAPSM). VII Congreso de Fisicoquímica, Estructura y Diseño de Proteínas.	

CONGRESOS INTERNACIONALES	24 Participaciones con ponencia 39 Participaciones con cartel
37 SMYTE (Small Meeting on Yeast Transport and Energetics).	
1er Congreso Internacional de Ciencias Químico Biológicas.	
27th Meeting of the International Society for Neurochemistry.	
30th Fungal Genetics Conference.	
63 Annual Meeting of the Biophysical Society.	
7th International Urogenital Science Meeting.	
FASEB-The Lysophospholipid and Related Mediators Conference: from bench to clinic.	
Humboldt Kolleg “Rompiendo Paradigmas: Hacia una Ciencia Multi, Inter y Transdisciplinaria”.	
Humboldt Kolleg: Symposium on Natural Science.	
III International Congress of Psychobiology.	
III International Symposium on Fungal Stress.	
XIII International Basal Ganglia Meeting.	
26th Meeting, Society for Redox Biology and Medicine. (SfRBM 2019).	
II Pan American Congress of Physiological Sciences - PANAM 2019.	
SGP 73 Annual Symposium/Sobla Annual Meeting. Reunión de la Sociedad Biofísica Latinoamericana y la Society for General Physiologists.	
3er Congreso Internacional de la Federación de Sociedades y Asociaciones Hispanas de América del Norte, Centroamérica y el Caribe de la Ciencia de los Animales de Laboratorio, A.C. (FeSAHANCCCAL).	
Federation of European Neuroscience Societies (FENS).	
XXIX International Conference on Yeast Genetics and Molecular Biology.	
20th International Symposium on Cells of the Hepatic Sinusoid (ISCHS).	
21th European Congress of Endocrinology (ECE 2019).	
22nd International *C. elegans* Conference.	
50th Annual meeting Society for Neuroscience.	
eGMD - Epigenetics in Metabolic Diseases // 3rd LIMIOR - Leipzig International Meeting for Interdisciplinary Obesity Research.	

5th International Meeting on Stem Cells and Regenerative Medicine.
EMBO Workshop: Protein Synthesis and Translational Control.
EMBO workshop Bridging cell and tissue mechanics to fate specification and development.
International Stroke Conference 2019.
3rd International Summer Symposium on Systems Biology.
ISSCR 2019 Annual Meeting
Parasitic helminths new perspectives in biology and infection.
VII Meeting of Reactive Oixgen Species in Biology and Medicine.
XIV European Meeting on Glial Cells in health and Disease.
BLAST XV. Bacterial, Locomotion and signal Transduction Meeting.
Association for Research in Vision and Ophthalmology (ARVO) Annual Meeting.
6 to. Congreso Internacional RedBiot.

Numero	Simposios, Conferencias y Seminarios	Participaciones
11	Simposios Nacionales con ponencia	15
	Simposios Nacionales con cartel	0
16	Simposios Internacionales con ponencia	20
	Simposios Internacionales con cartel	7
30	Conferencias Nacionales con ponencia	31

EVENTOS ACADÉMICOS INSTITUCIONALES

Los principales eventos académicos que se llevan a cabo en el Instituto de Fisiología Celular son fundamentalmente seminarios institucionales, que se realizan semana a semana, seminarios extraordinarios y la Feria Anual de Carteles.

En 2019 se llevaron a cabo 41 seminarios institucionales y 10 seminarios extraordinarios.

Seminarios Institucionales

ENERO

11 Dr. Richard Flavell, Yale University.
"To code or not to code: what is the Linc?".

18 Dr. Darío Lupiañez, Max Planck Institute for Molecular Genetics.
"Structural variation in the 3D genomic era: Implications for disease and evolution".

25 M. en C. Ana María Escalante Gonzalbo, Instituto de Fisiología Celular, UNAM.
"Los olvidados. ¿Puede la tecnología contribuir a la neuro-rehabilitación?".

FEBRERO

1 Dr. Víctor Manuel Valdés López, Facultad de Ciencias, UNAM.
"Teorías Evolutivas del Genoma Humano". Feria de Carteles.

8 Dr. Braulio Gutiérrez Medina, IPICYT (Instituto Potosino de Investigación Científica y Tecnológica A.C.).
"Luz y sombra en la proteína Vivid".

15 Dra. Yazmin Ramiro Cortes, Departamento de Neurodesarrollo y Fisiología, Instituto de Fisiología Celular, UNAM.
"Actividad sináptica y neuronal en ratones SHANK3 como modelo genético de autismo: de las espinas a la conducta".

22 Dra. Karina Acevedo Whitehouse, Facultad de Ciencias Naturales de la Universidad Autónoma de Querétaro.
"La carcinogénesis espontánea en un modelo marino".

MARZO

1 Dr. Stewart Gillmor, Langebio CINVESTAV Irapuato.
"Zygotic genome activation and pattern formation in early *Arabidopsis* embryogenesis".

8 Dra. Claudia Pérez Cruz, CINVESTAV-IPN.
"Modulación del eje intestino-cerebro como estrategia para combatir la enfermedad de Alzheimer".

15 Dr. Luis Téllez, Neurobiología de la Conducta Motivada, Instituto de Neurobiología, UNAM.
"El eje víscero-cerebral como parte del sistema de recompensa".

22 Dr. Luis Vaca, Departamento de Biología Celular y del Desarrollo, Instituto de Fisiología Celular, UNAM.
“Restricciones en el espacio-tiempo a nivel de moléculas individuales”.

29 Dr. Leonardo Peraza, Departamento de Bioquímica y Biología estructural, Instituto de Fisiología Celular, UNAM.
"Orquestando la dinámica intracelular durante el desarrollo sexual del hongo *Podospora*".

ABRIL

5 Dra. Paola Maycotte González, Investigadora Cátedras CONACyT. Centro de Investigación Biomédica de Oriente, IMSS.
"Secreción regulada por autofagia en cáncer de mama: implicaciones terapéuticas".

12 Dra. Daniela Araiza Olivera Toro, Departamento de Química de Biomacromoléculas, Instituto de Química, UNAM.
"Una molécula… un blanco terapéutico en el microambiente tumoral".

26 Dr. Luis Carrillo Reid, Instituto de Neurobiologia, UNAM.
“Cambios en el comportamiento inducidos por la activación selectiva de ensambles corticales.”

MAYO

3 Dra. Rocío Angeles García Becerra, Departamento de Biología Molecular y Biotecnología, Instituto de Investigaciones Biomédicas, UNAM.
“Restablecimiento de la respuesta a la terapia antiestrogénica en células de cáncer de mama receptor de estrógenos negativo.”

9 Dr. Carlos Manlio Díaz García, Department of Neurobiology, Harvard Medical School, Boston, MA.
"La estimulación neuronal promueve la glucólisis y no el consumo de lactato en las neuronas".

24 Dr. Francisco Torres Quiroz, Departamento de Bioquímica y Biología Estructural, Instituto de Fisiología Celular, UNAM.
"Papel del H2S durante la fermentación".

31 Dr. Óscar González-Pérez, Universidad de Colima.
"Consecuencias de la hidrocefalia crónico-obstructiva sobre los progenitores neurales y la citoarquitectura cerebral".

JUNIO

7 Dr. Diego Cortez Quezada, Centro de Ciencias Genómicas CCG, UNAM.
“Genomics of sexuality in vertebrates”.

14 Dr. José Everardo Avelino Cruz, Instituto de Fisiología, BUAP.
“Remodelación cardiaca en el síndrome metabólico y la diabetes”.

21 Dra. Tamara Rosenbaum Emir, Departamento de Neurociencia Cognitiva, Instituto de Fisiología Celular, UNAM.
"Canales TRP: moléculas que exhiben fenómenos biofísicos novedosos".

JULIO

26 Dra. Diana Guallar Artal, Principal Investigator at CiMUS (Center for Research in Molecular Medicine and Chronic Diseases). Santiago De Compostela, Galicia, España.
"Epitranscriptomics: shaping the cell through RNA modifications".

AGOSTO

2 Dr. Abimael Cruz Migoni, Universidad de Oxford.
“Finding small molecules inhibitors against oncogenic proteins”.

9 Dr. James L. McGaugh, Distinguished Professor Emeritus Department of Neurobiology and Behavior. Center for the Neurobiology of Learning and Memory. University of California, Irvine.
"Highly superior autobiographical memory research: A neurobiological puzzle".

16 Dr. Roberto Coria, Departamento de Genética Molecular, Instituto de Fisiología Celular, UNAM.
"Estrés de Retículo Endoplásmico y Autofagia en la Amiba Social *Dictyostelium discoideum".*

23 Dra. Diane Lipscombe, Brown University, USA.
"RNA and DNA binding proteins control the composition of calcium channels in nociceptors in normal and neuropathic pain states".

30 Dra. Maria Angela Franceschini, Associate Professor, Harvard Medical School, Massachusetts General Hospital.
"Imaging brain activity with diffuse optics: opportunities and future directions".

SEPTIEMBRE

6 Dra. Edda Lydia Scuitto Conde, Instituto de Investigaciones Biomédicas, UNAM.
"Hacia el desarrollo de nuevas estrategias para el control de la neuroinflamación: Implicaciones terapéuticas".

13 Dr. Francisco Barrantes, Pontifical Catholic University of Argentina, Buenos Aires, Argentina.
"Exploring the brain at the Nanoscale, in Health and Disease".

20 Dr. Joshua Johansen, RIKEN Center for Brain Science.
"Teaching the brain to fear".

27 Dr. Marcelo Wood, Universidad de California, Irvine, USA.
"Epigenetics: Pushing the boundaries of learning and memory".

OCTUBRE

4 Dr. Fatuel Tecuapetla, Departamento de Neuropatología Molecular, Instituto de Fisiología Celular, UNAM.
"Sub-circuitos neuronales detrás de la generación de movimientos/acciones".

11 Dr. Diego González Halphen, Departamento de Genética Molecular, Instituto de Fisiología Celular, UNAM.
"Cuando la subunidad 2 de la citocromo c oxidasa entra a la membrana interna mitocondrial por la puerta de atrás".

18 Dra. Rosaura Hernández Rivas, Departamento de Biomedicina Molecular CINVESTAV.
"El procesamiento de la histona H3: nuevo mecanismo epigenético que regula la expresión de genes que participan en la replicación del ADN en *Plasmodium falciparum*".

25 Dra. Carmen Sandi, Laboratory of Behavioral Genetics. Brain Mind Institute.
"Papel de la mitocondria en circuitos neurales que codifican conductas de ansiedad y depresión".

NOVIEMBRE

8 Dr. Ben Deverman, Stanley Center for psychiatric research en el Broad Institute of Harvard and MIT.
"Engineering AAV vectors for central nervous system gene therapy".

15 Dr. Félix Recillas Targa, Departamento de Genética Molecular, Instituto de Fisiología Celular, UNAM.
"Participación de la estructura tri-dimensional del genoma en la regulación transcripcional".

22 Dra. Alicia González Manjarrez, Departamento de Bioquímica y Biología Estructural, Instituto de Fisiología Celular, UNAM.
“Reguladores Híbridos: Una alternativa para provocar respuestas transcripcionales innovadoras en *S. cerevisiae*”.

29 Dra. Tatiana Fiordelisio, Laboratorio de Neuroendocrinología Comparada, Facultad de Ciencias, UNAM.
“La Unidad endocrino vascular en la vida real de la hipófisis de un ratón”.

DICIEMBRE

6 Dr. Jesús Chimal Monroy, Departamento de Medicina Genómica y Toxicología ambiental, Instituto de Investigaciones Biomédicas, UNAM.
"Del desarrollo embrionario y regeneración de las extremidades a la formación de organoides".

Seminarios Extraordinarios

ENERO

22 Dr. André S. Pupo, Departamento de Farmacología de la Universidad Estatal Paulista, Brasil.
"Therapeutic potential for biased agonism at alpha-1 adrenoceptors".

ABRIL

9 Dr. Alessandro Sette, Division of Vaccine Discovery, La Jolla Institute for Allergy and Immunology, California, USA.
"The relationship between alfa-synuclein-specific T cell reactivity and Parkinson Disease clinical onset".

25 Dr. Ya-Xiong Tao, Professor, Auburn University College of Veterinary Medicine, Alabama, USA.
"Chaperoning G protein-coupled receptors: From cell biology to therapeutics".

JULIO

31 Dr. Miguel Fidalgo, CIMUS-U de Santiago de Compostela, España.
"Deciphering the crosstalk of cellular metabolism and chromatin dynamics in pluripotency".

SEPTIEMBRE

12 Dra. Saydi Núñez Cetina, UAM-Xochimilco.
"De la violencia conyugal al feminicidio. Reflexiones sobre género y crimen pasional en el siglo XX mexicano".

26 Dr. Víctor G. Corces, Profesor Howard Hughes Medical Institute (HHMI), Investigador en la Universidad de Emory en Atlanta, GA.
"Herencia Transgeneracional de Epi-Fenotipos de Obesidad".

OCTUBRE

24 Dra. Lydiette Carrión Rivera.
"Femicidios y violencia de género: un fenómeno sistémico".

NOVIEMBRE

28 Dr. Dasiel Borroto-Escuela, Department of Neuroscience-Karolinska Institutet, Stockholm, Sweden.
"Molecular integration in the CNS through formation of GPCR heteroreceptor complexes: Relevance for diseases".

DICIEMBRE

4 Dr. Itay Tirosh, Department of Molecular Cell Biology, Weizmann Institute of Science.
"An integrated model of cellular heterogeneity in glioblastoma".

9 Dr. Pedro Bekinschtein, Instituto de Neurociencia Cognitiva y Translacional del CONICET, Argentina.
"Mecanismos biológicos de la memoria de reconocimiento y su olvido".

Feria de Carteles Anual del IFC

En la feria de Carteles 2019 se presentaron 62 trabajos. Se realizarón mini simposios y exposiciones cortas de los carteles, con lo que se promovío la discusión científica y el intercambio académico.

	Nombre	Laboratorio	Título del cartel
1	Roberto Alexander Bahena Cerón	Dr. Alfredo Torres Larios	Estudios estructurales sobre la proteína PyrR
2	Jesús Ruiz Flores	Dr. Francisco Torres Quiroz	Caracterización de los mecanismos post-traduccionales en las regiones de baja complejidad involucradas en la agregación reversible de proteínas en *Saccharomyces cerevisiae*
3	Rodrigo Andrés Nava Lara	Dr. Gabriel Del Río Guerra	Heterologous machine learning for the identification of antimicrobial activity in human-targeted drugs
4	Raful Navarro Espíndola	Dr. Leonardo Peraza Reyes	La dinámica peroxisomal y mitocondrial regulada por DNM1 es necesaria para el desarrollo sexual en el hongo *Podospora anserina*
5	Pamela Amancio Rojas	Dr. Leonardo Peraza Reyes	La dinámica de los endosomas y los peroxisomas regulada por Hok1 es necesaria para el desarrollo sexual del hongo *Podospora anserina*
6	Melisa Selene Álvarez Sánchez	Dr. Leonardo Peraza Reyes	La función del complejo de encuentro entre la mitocondria y el retículo endoplásmico (ERMES) en el hongo *Podospora anserina*
7	Oscar Eduardo Gutiérrez Castañeda	Dr. Marcelino Arciniega Castro	Simulaciones de dinámica molecular en canales iónicos
8	Sergio Campos Ortega Rendón	Dr. Marcelino Arciniega Castro	Detección de similitudes locales entre proteínas con dinámica molecular y teoría de gráficas
9	Francisco Javier Padilla Garfias	Dr. Antonio Peña Díaz	Efectos de la ε-poli-l-lisina sobre la fisiología de *saccharomyces cerevisiae*
10	Mariana Ríos Vázquez	Dra. Bertha González Pedrajo	Molecular characterization of rOrf1 protein of enteropathogenic *Escherichia coli*
11	Ameyalli Gómez Ilescas	Dr. Félix Recillas Targa	The role of CTCF in the nervous system of *Drosophila melanogaster*
12	Carlos Alberto Peralta Alvarez	Dr. Félix Recillas Targa	Regulación epigenética y transcripcional de RNAs no codificantes divergentes involucrados en cáncer
13	Andrés Arenas Navarro	Dr. Heliodoro Celis Sandoval	Caracterización del espectro de los centros de reacción de *Rhodovibrio salinarum*
14	Ayerim Alma Esquivel López	Dra. Mayra Furlán Magaril	Analysis of the chromosomal genomic interactions of homeotic genes in *Drosophila melanogaster* using different cross-linking reagents

	Nombre	Laboratorio	Título del cartel
15	Marintia Mayola Nava García	Dra. Mayra Furlán Magaril	3D organization of the SHH chromatin locus during feather bud formation in *Gallus gallus*
16	José Ernesto Bravo Arévalo	Dra. Soledad Funes	Regulación metabólica de las subunidades β-NAC en *Saccharomyces cerevisiae*
17	Hilario Ruelas Ramírez – Josué Miguel Julián Ramírez Reyes	Dra. Soledad Funes	El enigma de Slm35: de la mitocondria a la autofagia
18	Cristian Alberto Vergara Gerónimo	Dra. Xochitl Pérez Martínez	El factor de inicio de la traducción citoplasmática 4G1 es un regulador de la síntesis mitocondrial de Cox1
19	Diana Grisel Ríos López	Dra. Marina Macías	Regulación de la expresión de TAZ y el fenotipo del hepatocito
20	Karla Ameyali Gómez Ceja	Dra. Marina Macías	Regulación de la estabilidad de la proteína Ski por el antibiótico puromicina
21	Nallely Cano Domínguez	Dr. Jesús Aguirre Linares	Neurospora crassa multifunctional nadph oxidase Nox-1 is localized in the vacuolar system and the plasma membrane
22	Diego Pérez Vázquez	Dra. Paula Licona Limón	Función de TIF1-gamma en poblaciones de linfocitos Th1 y CTL
23	María Fernanda Maldonado	Dra. Paula Licona Limón	Regulación de la expresión de CD25 por TIF1g en linfocitos T reguladores
24	Eugenio Contreras Castillo	Dra. Paula Licona Limón	Regulación de la expresión de Foxp3 por TIF1g en linfocitos Treg
25	Emmanuel Flores Espinoza	Dra. Paula Licona Limón	Expresión del receptor de IL-9 en basófilos
26	Enrique Olguín Martínez	Dra. Paula Licona Limón	Participación de PKIB y la vía de PKA en la diferenciación y función de las células linfoides innatas tipo 2
27	Ofelia Muñoz Paleta	Dra. Paula Licona Limón	PKA y PKIB en la diferenciación y función de los linfocitos Th
28	Jose Luis Ramos Balderas	Dra. Paula Licona Limón	Caracterización de la respuesta inmune contra cepas de *Pseudomonas aeruginosa* resistentes a Galio
29	Alan Anuart González Rangel	Dra. Rosa Navarro González	Searching for regulators of lin-35/Rb expression during starvation in *C. elegans*
30	Laura Silvia Salinas Velázquez	Dra. Rosa Navarro González	PEK-1, ABCF-3 and GCN-1/-2 kinases are required for RNA granules formation during stress in the germline of *C. elegans*
31	Gisselle Angélica Campos Martínez	Dra. Rosa Navarro González	Stress induces mitochondrial aggregation in *Caenorhabditis elegans* adult gonad

	Nombre	Laboratorio	Título del cartel
32	Ángel Armando Dámazo Hernández	Dra. Rosa Navarro González	The RNA binding protein GLA-3/TTP is important for germ cell protection from stress
33	Eduardo Daniel Aguilar Solis	Dr. Víctor Julián Valdés Rodríguez	Caracterización epigenética de un circuito neuronal involucrado en la memoria asociativa de *C. elegans*
34	Marti David Wilson Verdugo	Dr. Víctor Julián Valdés Rodríguez	Characterization of epigenetic changes associated with the metabolic memory *in vitro*
35	Teresa Beatriz Nava Ramírez	Dr. Wilhelm Hasnberg Torres	La función de chaperona de las catalasas de subunidad grande
36	Sammy Israel Gutiérrez Terrazas	Dr. Wilhelm Hasnberg Torres	La actividad de fosfodiesterasa en *Neurospora crassa* está involucrada en formación de la pared celular
37	Oscar Giovanny Urrego Morales	Dr. Federico Bermúdez Rattoni	Effect of the inhibition of palmitoylation on the formation and maintenance of spatial memory
38	Beatríz Sarahí Méndez Rodríguez.	Dra. Elvira Galarraga Palcio	Posible comunicación sináptica entre las neuronas de los núcleos intralaminares del tálamo parafascicular y central lateral (Possible synaptic communication between neurons of Parafascicular and Central lateral intralaminar thalamic nuclei)
39	Rosa María Reyes Chapero	Dra. Elvira Galarraga Palcio	Cortical persistent activity in pyramidal and interneurons of layer 5 motor cortex *in vitro*
40	Yuriko Itzel Sánchez Zamora	Dra. Marcia Hiriart Urdanivia	Dimorfismo sexual en la inflamación presente en un modelo de síndrome metabólico en rata
41	Jazmín Selene Samario Román	Dra. Marcia Hiriart Urdanivia	El papel de NGF en la expresión y actividad de GLUT2 y glucocinasa en células beta pancreáticas
42	Zyanya Sarai Sánchez Salazar	Dra. Marcia Hiriart Urdanivia	Análisis del desarrollo y la distribución de las células α y células PP en el páncreas de rata después del destete
43	Rosa Isela Ortiz Huidobro	Dra. Marcia Hiriart Urdanivia	En la resistencia a la insulina...el sexo si importa.
44	Carla Huezca Carbajal	Dra. Tamara Rosenbaum Emir	Dimorfismo sexual en la respuesta de dolor asociada al canal TRPV1 por efecto del 17B-estradiol
45	Iskra Anai Cruz Cruz	Dra. Myrian Velasco Torres	Efecto del síndrome metabólico sobre el funcionamiento de los canales de potasio sensibles a ATP
46	Germán Alonso Bernate Obando	Dra. Myrian Velasco Torres	Red de co-expresión de los canales de potasio dependientes de voltaje Kv2 en célula beta a diferentes estadios del desarrollo
47	Viridiana Belen Meza González	Dra. Diana Escalante Alcalde	Generación de dos líneas de ratones con mutaciones en la PLPP3
48	Beetsi Eugenia Urrieta Chávez	Dr. Iván Velasco Velázquez	Uso de un hidrogel biocompatible para el direccionamiento de axones de neuronas dopaminérgicas humanas

	Nombre	Laboratorio	Título del cartel
49	Pilar Sarah Acevo Rodríguez	Dra. Susana Castro Obregón	La autofagia podría cooperar con las metaloproteínasas de la matriz en el cierre del tubo neural del ratón
50	Daniel Moreno Blas	Dra. Susana Castro Obregón	Autophagy dysfunction during neuronal senescence
51	Emiliano Jimenez Marquez	Dra. Yazmín Ramiro Cortés	Actividad neuronal en corteza visual de ratones SHANK3+/- en respuesta a una tarea visual de sobre-especificidad
52	Rubén Darío Contreras López	Dr. Fatuel Tecuapetla Aguilar	Ciurcuitos de interacción cerebelo - ganglios basales
53	Luis Antonio Rodríguez Sibrian	Dr. Fatuel Tecuapetla Aguilar	Caracterización de los circuitos paralelos o divergentes de salida del tálamo
54	Anil Kumar Verma Rodríguez	Dr. Fatuel Tecuapetla Aguilar	Disección de circuitos neurales involucrados en la estimulación cerebral profunda con técnicas de optogenética
55	Alejandra Aidaly Hernández Jaramillo	Dr. Francisco Sotres Bayón	Basolateral amygdala and ventral pallidum (but not orbitofrontal cortex) are necessary for motivational conflict responses guided by previous experiences
56	Diana Lizbeth Elías López	Dr. Juan Carlos Gómora Martínez	Efecto de compuestos con propiedades anti metastásicas en el canal Nav1.6 de humano
57	Luis Ángel Montes Ortega	Dra. Lourdes Massieu Trigo	Effect of D-hydroxybutyrate in autophagy induction by exitototxicity
58	Juan Carlos Gómora García	Dra. Lourdes Massieu Trigo	La respuesta a proteínas mal plegadas inducido por la ausencia de glucosa en neuronas corticales ¿Amigo o Enemigo?
59	Aura Nirva Campero Romero	Dr. Luis Tovar y Romo	Proteomic profiling of exosomes derived from brain microvascular endothelial cells under hypoxia
60	Diana Elizabeth Colín Martínez	Dr. Ricardo Tapia	Efectos de la administración aguda y crónica de inhibidores de la glutamato descarboxilasa en la médula espinal de rata
61	Ximena Ameyalli Escutia Macedo, David Andrade Morales, María Fernanda Gutiérrez García y José Jonathan Aguilar Chalé.	M. C. Ana María Escalente Gonzalbo	Hágalo usted mismo: autonomía y motivación con el uso de la tecnología en la neuro-rehabilitación
62	Edgar Gerardo Milo Rocha	Dr. Enoch Luis Baltazar	Estudio electrofisiológico y farmacológico del canal de potasio Kv10.1

ACTIVIDADES DE DIFUSIÓN Y DIVULGACIÓN

Participaciones en radio y televisión	**30**
Participaciones en medios impresos	**24**
Otras actividades de Difusión o divulgación (Conferencias, simposios, ferias)	**72**

Participaciones en Programas de Radio o Televisión

1. Aguilar Roblero Raúl. Entrevista en Mitos y Realidades de Canal Once, para tratar el tema del Cambio de Horario (ventajas y desventajas) tanto en el terreno de impacto en la salud para el ser humano como el impacto económico por el ahorro de energía.

2. Bermúdez Rattoni Federico. Entrevista en 24 horas. “Alzheimer, afecta a 800 mil mexicanos”. https://www.24-horas.mx/2019/09/23/alzheimer-afecta-a-800-mil-mexicanos/

3. Bermúdez Rattoni Federico. Entrevista en Acrópolis. “Se deben prevenir casos de Alzheimer en México: especialistas”. https://acropolismultimedios.mx/se-deben-prevenir-casos-de-alzheimer-en-mexico-especialistas/

4. Bermúdez Rattoni Federico. Entrevista en ADN Sureste. ” ¿Mala memoria o falta de atención?”. https://www.adnsureste.info/mala-memoria-o-falta-de-atencion-1000-h/

5. Bermúdez Rattoni Federico. Entrevista en AFMedios. “En México, padecen Alzheimer 800 mil personas; retos cognitivos una opción para retrasar aparición”. https://www.afmedios.com/2019/09/en-mexico-padecen-alzheimer-800-mil-personas-retos-cognitivos-una-opcion-para-retrasar-aparicion/

6. Bermúdez Rattoni Federico. Entrevista en Bajo Palabra. “Epidemia de Alzheimer amenaza a México”. https://bajopalabra.com.mx/epidemia-de-alzheimer-amenaza-a-mexico

7. Castro Obregón Susana. Entrevista en ADN Sureste. “¿Se pueden crear nuevas neuronas?” http://adnsureste.info/se-pueden-crear-nuevas-neuronas-1600-h/

8. Escalante Alcalde Diana. Entrevista en Diálogos en Confianza, Canal Once. “Avances en el uso y tratamiento con células madre”.

9. Escalante Gonzalbo Ana María. Entrevista en Agencia EFE. “México utiliza videojuegos para sanar a pacientes con daños neuronales”.

10. Escalante Gonzalbo Ana María. Entrevista en CCNews. “UNAM crea videojuegos para rehabilitar a pacientes con daño cerebral”. https://news.culturacolectiva.com/ciencia/unam-crea-videojuego-para-rehabilitar-a-pacientes-con-dano-cerebral/

11. Georgellis Dimitris y Álvarez F. Adrián. Entrevista en RT en español. “Qué “sienten” las bacterias y por qué es importante para acabar con la resistencia a los antibióticos”. https://actualidad.rt.com/actualidad/330445-sienten-bacterias-importante-acabar-resistencia-antibioticos.

12. Hiriart Urdanivia Marcia. Entrevista en ADN 40. “Día Internacional de la Mujer y la Niña en la Ciencia”.

13. Hernández Cruz Arturo. Reportaje en Factor Ciencia, Canal 11. "Células Madre”. https://youtu.be/ns82zY9MT9w.

14. Hernández Muñoz Rolando. Entrevista en 20 minutos. “UNAM obtiene patente para proteger hígado en pacientes con VIH”. 20minutos.com.mx/noticia/

15. Hernández Muñoz Rolando. Entrevista en CND Cadena Digital de Noticias. “UNAM patenta medicamento para proteger hígado de personas con SIDA”. https://www.cdnoticias.com.mx/articulos/unam-patenta-medicamento-proteger-higado-personas-sida/portada

16. López Colomé Ana María. Entrevista en TV UNAM, Espacio académico AAPAUNAM TV. Cápsula de 5 minutos dirigida al público en general.

17. Osorio Gómez Daniel. Entrevista en Radio Educación, programa Paisaje Interno con el tema memoria. Locutora Ana Leticia Vargas.

18. Pasantes Ordóñez Herminia. Entrevista en Canal Once. “El amor es como la materia”. 22 febrero 2019.

19. Pasantes Ordóñez Herminia. Serie Hipócrates 2.0 coproducida por el Programa Universitario de Investigación en Salud y Radio UNAM. “Neurociencias, la licenciatura en la UNAM”.

20. Pérez de la Mora Miguel. Entrevista en ADN 40. “Más de 264 millones de personas en el mundo viven con ansiedad”.

21. Ramirez Graullera Yoas Saimon. Entrevista en ADN 40. “UNAM desarrolla videojuegos para terapia virtual de rehabilitación”. https://www.adn40.mx/noticia/salud/nota/2019-03-31-12-15/unam-desarrolla-videojuegos-para-terapia-virtual-de-rehabilitacion/

22. Recillas Targa Félix. Entrevista en ADN Sureste. “Estudio del genoma del ajolote ayudará en la lucha contra el cáncer”. https://www.adnsureste.info/estudio-del-genoma-del-ajolote-ayudara-en-la-lucha-contra-el-cancer-1100-h/

23. Recillas Targa Félix. Entrevista en Creadores Universitarios, TV UNAM. “Implicaciones de la modificación genética en humanos”.

24. Recillas Targa Félix. Entrevista en Data Noticias. “El estudio del ajolote podría ser clave para ayudar a curar el cáncer”. https://www.datanoticias.com/2019/08/24/el-estudio-del-ajolote-podria-ser-clave-para-ayudar-a-curar-el-cancer/

25. Romo Trujillo Ranulfo. Entrevista en 20 minutos. “Ranulfo Romo: un científico que ha educado sus neuronas”. https://www.20minutos.com.mx/noticia/503376/0/ranulfo-romo-un-cientifico-que-ha-educado-sus-neuronas/

26. Rosenbaum Emir Tamara. Entrevista en ADN Sureste. “Descifrando los mecanismos del dolor y otros transtornos”. https://www.adnsureste.info/basicamente-ciencia-descifrando-los-mecanismos-del-dolor-y-otros-trastornos-0900-h/

27. Tapia Ibargüengoytia Ricardo. Entrevista en el canal 11, con Javier Solórzano.

28. Tapia Ibargüengoytia Ricardo. Participación en la serie de televisión Observatorio Semanal de TV-UNAM, con el tema “Modificación genética”.

29. Tapia Ibargüengoytia Ricardo. Entrevista en ADN 40 en el programa “No hay lugar común”.

30. Velasco Velázquez Iván. Entrevista en América Retail. “Neuromarketing: se pueden crear neuronas *in vitro* similares a las humanas”. https://www.america-retail.com/featured/neuromarketing-se-pueden-crear-neuronas-in-vitro-similares-a-las-humanas/

Participaciones en Medios Impresos

1. Aguilar Roblero Raúl. Entrevista en Periódico Reforma. https://www.playbuzz.com/gruporeforma/cambio-de-hora-un-debate-mexicano-y-mundial.

2. Aguilar Roblero Raúl. Entrevista en El Heraldo de Tabasco. “Horario de Verano, mame de los diputados”. https://www.elheraldodetabasco.com.mx/analisis/horario-de-verano-mame-de-los-diputados-3284149.html.

3. Álvarez Adrián Fernando. Entrevista en Actualidad RT. https://actualidad.rt.com/actualidad/330445-sienten-bacterias-importante-acabar-resistencia-antibioticos.

4. Álvarez Adrián Fernando. Entrevista en Excélsior. “Comprendiendo cómo sienten las bacterias”. https://www.excelsior.com.mx/nacional/comprendiendo-como-sienten-las-bacterias/1327538.

5. Bermúdez Rattoni Federico. Entrevista en DGCS. "Padecen alzhéimer unas 800 mil personas en México”. Día Mundial del Alzheimer.

6. Bermúdez Rattoni Federico. Entrevista en UNAM Global. “¿Mala memoria o falta de atención? “http://www.unamglobal.unam.mx/?p=69829.

7. Bermúdez Rattoni Federico. Entrevista en El Universal. “¿Por qué recuerdas tu primer beso? La ciencia te lo explica”. https://www.tangible-eluniversal.com.mx/por-que-recuerdas-tu-primer-beso-la-ciencia-te-lo-explica.

8. Del Río Guerra Gabriel. Entrevista en la revista Análisis jurídico, en torno al tema de la inteligencia artificial (análisis previo a las implicaciones normativas). https://www.youtube.com/watch?v=TS2P8WSzNw4&t=3s.

9. López Colomé Ana María. Entrevista con Paco Zea. “Cinco mexicanas que destacan en la ciencia”. https://www.pacozea.com/cinco-mexicanas-que-destacan-en-la-ciencia.

10. López Colomé Ana María. “10 mexicanas científicas que con sus conocimientos han puesto al país en alto”. htpps://www.sinembargo.mx/03-01-2019/3517715.

11. López Huerta Violeta. Entrevista en Gaceta UNAM. “Nuevas opciones para tratar males psiquiátricos”. https://www.gaceta.unam.mx/tag/optogenetica/.

12. Massieu Trigo Lourdes. Entrevistas en El Universal. "Hipoglucemia y muerte neuronal".

13. Massieu Trigo Lourdes. Entrevista en Gaceta UNAM. "La glucosa, básica para el funcionamiento neurona".

14. Pasantes Ordóñez Herminia. Entrevista en Colima noticias. “Las mujeres tenemos en mayor porcentaje un cerebro creativo: Herminia Pasantes”. http://www.colimanoticias.com/las-mujeres-tenemos-en-mayor-porcentaje-un-cerebro-creativo-herminia-pasantes/.

15. Peña Díaz Antonio. Entrevista en Una Mirada a la Ciencia, DGDC, UNAM. “Las levaduras: ¿Cómo han servido a la humanidad?”.

16. Peña Díaz Antonio. Entrevista en El Universal. “Cómo las levaduras benefician a la humanidad”. https://www.eluniversal.com.mx/ciencia-y-salud/como-las-levaduras-benefician-la-humanidad.

17. Pérez de la Mora Miguel. Entrevista en Gaceta UNAM. “La ansiedad ¿Amiga o Enemiga?”. No.5036 ISSN 01885138 Pag.10.

18. Pérez de la Mora Miguel. Entrevista en Diario de Morelos. “Trastorno de ansiedad”. https://www.diariodemorelos.com/noticias/trastorno-de-ansiedad.

19. Ramirez Graullera Yoas Saimon. Entrevista en Crónica. “UNAM registra videojuegos para rehabilitar a personas con accidentes cerebrovasculares”. http://www.cronica.com.mx/notas/2019/1113609.html.

20. Recillas Targa Félix. Entrevista en el periódico Milenio. “Avances genéticos que están revolucionando a la ciencia”. https://www.milenio.com/especiales/la-revolucion-genetica.

21. Romo Trujillo Ranulfo. Entrevista en Gaceta UNAM. “El amor y el cerebro”. http://www.gaceta.unam.mx/el-amor-y-el-cerebro/.

22. Rosenbaum Emir Tamara. Entrevista en La Crónica. “Los canales iónicos determinan como las células perciben y reaccionan a su entorno”. https://www.cronica.com.mx/notas-los_canales_ionicos_determinan_como_las__celulas_perciben_y_reaccionan_a_su_entorno_tamara_luti_rosenbaum_emir-1135603-2019.

23. Rosenbaum Emir Tamara. Entrevista en Gaceta UNAM. "La emoción, respuesta fisiológica y aprendida". https://www.gaceta.unam.mx/la-emocion-respuesta-fisiologica-y-aprendida/.

24. Valdés Rodríguez Julián. Entrevista en El Heraldo de México. “El cordón umbilical, ¿es un mito?”. https://heraldodemexico.com.mx/estados/el-cordon-umbilical-es-un-mito/.

Otras actividades de Difusión o Divulgación

1. Aguilar Roblero Raúl. Conferencia. "Llevando el ritmo de vida: Los relojes que gobiernan la vida". Ciclo: Los Domingos en la Ciencia. Academia Mexicana de Ciencias.

2. Aguirre Linares Jesús. Charla. “De toxicidad y regulación: El papel de especies reactivas de oxígeno en la diferenciación celular”. Fiesta de las Ciencias y las Humanidades. Museo de las Ciencias Universum, UNAM.

3. Álvarez Adrián Fernando. Conferencia. "Más de cinco sentidos: cómo sienten las bacterias por medio de su membrana celular." Fiesta de las Ciencias y las Humanidades. Museo de las Ciencias Universum, UNAM.

4. Álvarez Adrián Fernando. Conferencia. “¿Cómo sienten las bacterias?”. Sitio UNAM global. http://www.unamglobal.unam.mx/?p=69576.

5. Arciniega Castro Marcelino. Conferencia. “Opsinas: Proteínas de la visión”. Museo de la Luz.

6. Castro Obregón Susana. Conferencia. “Biología comparada para estudiar el envejecimiento”. Humboldt Kolleg: “El cosmos Mexicano de Humboldt”. El Colegio Nacional.

7. Castro Obregón Susana. Conferencia magistral. “¿Cómo hacer ratones fluorescentes y para qué?” en el 6to curso teórico-práctico de Biología Molecular para profesores de bachillerato: regulación de la expresión génica

8. Crespo Ramírez Minerva. Semana de la Ciencia y Tecnología dando unas platicas en el centro cultural COP,S.C del 11 al 15 de marzo del 2019 con número de adscripción a la SEP 51-3309-561-Px-02 CCT.09PPR1951Y

9. Escalante Alcalde Diana. Semana del Cerebro, IFC-UNAM.

10. Fernández de Miguel Francisco. Conferencia magistral. “¿Qué nos enseñan los murales prehispánicos de nuestra percepción visual?” XXVII Congreso Nacional de la Sociedad Mexicana de Psicología, A.C.Universidad de Guadalajara.

11. Funes Argüello Soledad. Charla. ¡Quiero ser científica! Centro Cultural España.

12. Georgellis Dimitris, Álvarez Adrián Fernando. Conferencia. “Cómo “sienten” las bacterias”. sección Campus–Ciencia, UNAM global. http://www.unamglobal.unam.mx/?p=69576.

13. González Manjarrez Alicia. Seminario. “Cómo influyen nuestros genes en lo que comemos: en la salud y la enfermedad”. 40 edición de la Feria Internacional del Libro del Palacio de Minería.

14. González Manjarrez Alicia. Coordinadora del Programa de Divulgación de la Ciencia. En la 40 edición de la Feria Internacional del Libro del Palacio de Minería.

15. González Pedrajo Bertha. Participación en el video de promoción del IFC. TV UNAM.

16. Hiriart Urdanivia Marcia. Conferencia. "Lo amargo del Azúcar". Centro Regional de Cultura Chimalpahin, Chalco, Edo. de México. Programa de la Academia Mexicana de Ciencias "Domingo en las Ciencias".

17. Lemus Sandoval Luis. Conferencia. “Sensación y percepción: nada es lo que parece”. Curso para profesores de bachillerato.

18. Lemus Sandoval Luis. Conferencia. “Alexa: ¿cómo reconoce el cerebro las palabras?”. Facultad de Medicina, UNAM.

19. López Huerta Violeta Gisselle. Panel. “Mujeres en Ciencia e Investigación”. Talent Woman.

20. López Huerta Violeta Gisselle. Plática de divulgación. “¿Se puede manipular el cerebro vía control remoto?”. Semana del Cerebro, IFC-UNAM.

21. López Huerta Violeta Gisselle. Plática de divulgación. “Cerebros a control remoto” Neurofest. Universum, UNAM.

22. Luis Baltazar Enoch. Visita guiada a alumnos y profesores de la Escuela Nacional Preparatoria, durante la Tercera jornada académica de estudiantes de la ENP y el Instituto de Fisiología Celular de la UNAM. Semana del Cerebro.

23. Mas Oliva Jaime. Participación en Infografía en el sitio Ciencia UNAM de la Dirección General de Divulgación de la Ciencia (DGDC). “¿Cómo funciona el calcio en nuestro cuerpo?”. http://ciencia.unam.mx/contenido/infografia/76/el-calcio-en-nuestro-cuerpo.

24. Navarro González Rosa Estela. Charla. ¡Quiero ser científica! Centro Cultural España.

25. Osorio Gómez Daniel. Charla. “Desvelos Científicos: Inception”. Noches de ciencia para adultos. Centro Cultural España.

26. Pasantes Ordóñez Herminia. Conferencia inaugural. “Las drogas y el cerebro”. Diplomado en Política de Drogas, Salud y Derechos Humanos. Aguascalientes Auditorio CIDE.

27. Pasantes Ordóñez Herminia. Conferencia. “¿Qué pasa en nuestro cerebro cuando nos enamoramos?”. IPN.

28. Pasantes Ordóñez Herminia. Conferencia. “Un viaje a tu cerebro”. Museo de Ciencias Universum, UNAM.

29. Pasantes Ordóñez Herminia. Conferencia. “Cerebro y creatividad”. Archivo Histórico del Municipio de Colima.

30. Pasantes Ordóñez Herminia. Conferencia. “Marihuana, cerebro y sociedad”. Seminario de Cultura Mexicana, Corresponsalía Córdoba, Veracruz.

31. Pasantes Ordóñez Herminia. Conferencia. “El cerebro y los límites de la libertad”. Escuela Nacional de Antropología e Historia.

32. Pasantes Ordóñez Herminia. Conferencia. “Dr. Ricardo Tapia: scientist, university profesor and my friend”. Facultad de Química e Instituto de Fisiología Celular, UNAM.

33. Pasantes Ordóñez Herminia. Conferencia. “El cerebro y los límites de la libertad”. Universidad Autónoma del Estado de México.

34. Pasantes Ordóñez Herminia. Conferencia. “Las funciones cerebrales y las adicciones”. Universidad Pedagógica Nacional.

35. Pasantes Ordóñez Herminia. Conferencia. “El cerebro y los límites de la libertad”. Auditorio del Centro de las Artes de la Universidad de Sonora.

36. Pasantes Ordóñez Herminia. Conferencia. “El funcionamiento del cerebro humano”. Universidad Etac, Aliat Universidades, Campus Coacalco.

37. Pasantes Ordóñez Herminia. Conferencia. “El amor y las neuronas espejo”. Universidad Don Vasco, Uruapan Michoacán.

38. Pasantes Ordóñez Herminia. “Seminario de Política de Drogas”. Universidad Autónoma de San Luis Potosí.

39. Pasantes Ordóñez Herminia. Conferencia. “De neuronas, emociones y motivaciones”. Escuela Nacional Preparatoria, Secretaría de Difusión Cultural, San Ildefonso.

40. Pasantes Ordóñez Herminia. Conferencia. “Retos y perspectivas de las neurociencias”. Auditorio del HGZ no. 7 del IMSS.

41. Pasantes Ordóñez Herminia. Conferencia. “Marihuana, cerebro y sociedad”. Aula Magna Carlos Helguera.

42. Pasantes Ordóñez Herminia. Conferencia. “Retos y perspectivas de las Neurociencias”. Museo del Ferrocarril, Empalme, Sonora.

43. Pasantes Ordóñez Herminia. Conferencia. “Creatividad y cerebro”. Seminario de Cultura Mexicana, Corresponsalía La Paz, Baja California Sur.

44. Pasantes Ordóñez Herminia. Conferencia. “Mariguana, cerebro y sociedad”. Universidad de Colima.

45. Pasantes Ordóñez Herminia. Conferencia. “Cerebro y creatividad”. 4° festival de Neurociencias ¡Prende tu cerebro! (NEUROFEST). Foro de Química en Universum, UNAM.

46. Pasantes Ordóñez Herminia. Conferencia. “El cerebro y los límites de la libertad”. Leamos la Ciencia para todos. Preparatoria 6 UNAM.

47. Pasantes Ordóñez Herminia. Conferencia Magistral. “El cerebro y los límites de la libertad”. Instituto Nacional de Medicina Genómica, 5° encuentro estudiantil.

48. Pasantes Ordóñez Herminia. Conferencia. "Cerebro y creatividad". Sociedad Mexicana de Dermatología.

49. Pérez de la Mora Miguel. Conferencia. “Transtorno de Ansiedad”. Semana del Cerebro, IFC-UNAM.

50. Pérez Martínez Xochitl. Conferencia. "Máquinas moleculares, luces y comunicaciones celulares". Jornada de conferencias y evento de puertas abiertas del IFC.

51. Pérez Martínez Xochitl. Charla. ¡Quiero ser científica! Centro Cultural España.

52. Peña Segura Claudia. Taller. “¡No todo es verde! Fotosíntesis bacteriana!” Desvelos científicos, noches de ciencia para adultos. Centro Cultural España.

53. Ramirez Graullera Yoas Saimon. Conferencia. “Desarrollo de videojuegos para la neurorehabilitación”. Semana del Cerebro, IFC-UNAM.

54. Ramiro Cortés Yazmín. Conferencia. “Las espinas del cerebro de un ratón tipo autista”. Semana del Cerebro, IFC-UNAM.

55. Ramiro Cortés Yazmín. Charla. ¡Quiero ser científica! Centro Cultural España.

56. Recillas Targa Félix. Participación en el Café Científico, Ciencia+Cultura. “Edición genética en humanos: alcances y riesgos”. Centro Cultural UNAM, Morelia.

57. Romo Trujillo Ranulfo. Conferencia. “¿Estás seguro que tu tomas tus decisiones?”. San Luis Potosí.

58. Romo Trujillo Ranulfo. Conferencia. “El cerebro arquitecto de realidades”. Universidad de Sonora.

59. Sotres Francisco. Participación en el video de promoción del IFC. TV UNAM.

60. Tapia Ibargüengoytia Ricardo. Conferencia. “Las Neurociencias y las drogas: ¿por qué no deben estar prohibidas?”. Charlas con premios nacionales en colaboración con consejo consultivo de ciencias.

61. Tapia Ibargüengoytia Ricardo. Taller Somos cerebro. “Neuroética: ¿Qué hacer con el conocimiento de las neurociencias?”. Festival de la salud emocional.

62. Tapia Ibargüengoytia Ricardo. Conferencia. Neuroética: ¿Qué hacer con el conocimiento de las neurociencias? Semana del Cerebro.

63. Tecuapetla Aguilar Fatuel. Conferencia. “Para iniciar acciones se requiere a los circuitos dopaminérgicos y a los del tálamo”. Evento De sinapsis, ensambles y sistemas dinámicos.

64. Tovar y Romo Luis Bernardo. Conferencia. “Participación de las vesículas extracelulares en el proceso de recuperación después del infarto cerebral isquémico”. Evento De sinapsis, ensambles y sistemas dinámicos.

65. Tuena de Gómez Marietta. Presentaciónes del libro del Dr. Gómez Puyou. "Conociendo las Moléculas de la Vida ´un viaje inesperado". IFC- UNAM. Museo Universum-UNAM y XXI Congreso de Bioenergética y Biomembranas, San Luis Potosí.

66. Uribe Carvajal Salvador. Conferencia. “Endosimbiosis y enfermedades por organismos intracelulares”. Fiesta de las Ciencias y las Humanidades. Museo de las Ciencias Universum, UNAM.

67. Vaca Dominguez Luis Alfonso. Conferencia. “Debates en torno al futuro de la educación, la ciencia y la tecnología en México”. 40 Feria Internacional del Libro del Palacio de Minería.

68. Velasco Loyden Nora Gabriela. Charla. ¡Quiero ser científica! Centro Cultural España.

69. Velasco Velazquez Iván. Conferencia. “¿Cómo podemos producir neuronas de nuestro cerebro fuera del cuerpo?” Programa de Divulgación Científica "Domingos en la Ciencia" de la Academia Mexicana de Ciencias. Universidad Autónoma Metropolitana, campus Iztapalapa.

70. Valdés Rodríguez Víctor Julián. Plática de divulgación. "Epigenética y Medio Ambiente". Preparatoria No. 6, UNAM.

71. Valdés Rodríguez Julián. Conferencia. “Epigenética y memoria: en busca de las claves de la interacción entre genes y ambiente”. Fiesta de las ciencias y las humanidades. Museo de las Ciencias Universum, UNAM.

72. Valdés Rodríguez Julián. Mesa Redonda. “Ethics Dumping ¿El fin justifica los medios?”. Jueves de Ciencia. Casa de Francia. IFAL CdMx.

PREMIOS Y DISTINCIONES

1) Ayala Méndez Xóchitl Gabriela. Prórroga del Estímulo Especial “Federico Fernández Cancino”. Universidad Nacional Autónoma de México. Consejo Técnico de la Investigación Científica. 15-Febrero- 2019.

2) Bargas José. Mejor Servicio Social Gustavo Baz Prada. Alumno Yael Chavarría. UNAM. Facultad de Medicina. CdMx. 14-noviembre-2019.

3) Lara González, Esther; Duhne, Mariana; Ávila Cascajares, Fátima; Cruz, Silvia; Bargas, José. Implementación de un nuevo bioensayo farmacologico in vitro utilizando imagenología de calcio. Premio de la cámara nacional de la industria farmacéutica. CdMx. 31-octubre-2019.

4) Mas Oliva Jaime. Premio Universidad Nacional 2019. Área Ciencias Naturales. Universidad Nacional Autónoma de México. CdMx. 31-octubre-2019.

5) Méndez Maldonado, Karla; Vega López, Guillermo; Caballero Chacón, Sara;. Aybar, Manuel J; Velasco, Iván. Tercer lugar de la categoría Investigación Básica por el trabajo: “Células Troncales embrionarias de ratón que expresan MSX1 y HES1 incrementan la diferenciación a derivados de cresta neural” en la XXXIV Reunión anual de Investigación del Instituto. Instituto Nacional de Neurología y Neurocirugía "Manuel Velasco Suárez". CdMx. 17-mayo-2019.

6) Montiel Montes Teresa. Medalla “Sor Juana Inés de la Cruz”. Universidad Nacional Autónoma de México. CdMx. 8-marzo-2019.

7) Pérez Martínez Xochitl. Medalla José Laguna García. Reconocimiento por sus contribuciones a la Bioenergética y a las Biomembranas, otorgado a científicos menores de 50 años de edad. Rama de Bioenergética y Biomembranas de la Sociedad Mexicana de Bioquímica. San Luis Potosí. 10-noviembre-2019.

8) Pérez Martínez Xochitl. Apoyo económico otorgado a un grupo selecto de 15 científicos para asistir al EMBO Workshop on Protein Synthesis and Translational Control. EMBL Corporate Partnership Programme Fellowship. Alemania. 4-septiembre-2019.

9) Romo Trujillo Ranulfo. Cátedra Hugo Aréchiga. El Colegio de Sinaloa. Culiacán, Sinaloa. 11-marzo-2019.

10) Romo Trujillo Ranulfo. Premio Crónica 2019 en Ciencia y Tecnología. Revista Crónica, CdMx.

11) Sosa Garrocho Marcela. Renovación por tercera ocasión del Estímulo especial “Guillermo Massieu”, obtenido por desempeño.

12) Tapia Ricardo. Symposium en honor de Ricardo Tapia “Chemical transmission: the key to understanding brain function”. Facultad de Química, Instituto de Fisiología Celular, UNAM. CdMx. 23-abril-2019.

13) Tecuapetla Aguilar Fatuel. Cátedra de investigación para jóvenes científicos Moshinsky 2019. Fundación Moshinsky. Instituto de Física. UNAM. CdMx. 21-noviembre- 2019.

FUENTES DE FINANCIAMIENTO

Proyectos Financiados por DGAPA

1. Aguilar Roblero Raúl. Proyecto: "Manejo del cloro en neuronas del Núcleo Supraquiasmático y su participación en el reloj circadiano". IN205917. 01/2017-12/2019. Monto: $ 260,000.

2. Aguirre Linares Jesús. Proyecto: "La comunicación intracelular, intercelular e inter-reino en los hongos". IV200519. 01/2019-12/2019. Monto: $ 3, 479,004.

3. Aguirre Linares Jesús. Proyecto: "Las especies de oxígeno reactivas como señales reguladoras del citoesqueleto de actina y la dinámica y comunicación entre organelos celulares en los hongos". IN200719. 01/2019-12/2019. Monto: $ 240,000.

4. Álvarez Adrián Fernando. Proyecto: " Organización y función de microdominios membranales bacterianos". IN208718. 01/2018-12/2020. Monto: $ 240,000.

5. Arciniega Castro Marcelino. Proyecto: "Identificación de rutas alostéricas en la proteína PyrR de *Bacillus Halodurans* emplenado simulaciones de dinámica molecular, teoría de gráficase e información mutua". IN213320. 01/2020-01/2021. Monto: $ 246,280.

6. Bargas Díaz José. Proyecto: "Signos electrofisiológicos de la enfermedad de Parkinson en los Ganglios Basales: su posible uso como bioensayo farmacológico". IN201417. 03/2017- 12/2019. Monto: $ 250,000.

7. Bargas Díaz José. Proyecto: "Estudio de las discinesias inducidas por L-DOPA y de la modulación muscarínica de los canales de Ca2+ en las neuronas estriatales de roedor en un modelo Parkinsoniano". IN222920. 01/2020-12/2022. Monto: $ 260,000.

8. Castro Obregón Susana. Proyecto: "Estudio de la autofagia nuclear como respuesta al daño al DNA y en la senescencia celular". IN206518. 01/2019-12/2019. Monto: $ 240,000.

9. Chagoya de Sánchez Victoria. Proyecto: "Regulación de los genes mitocondriales durante la carcinogénesis en un modelo secuencial de cirrosis - carcinoma hepatocelular y el efecto del hepatoprotector IFC-305". IN214419. 01/2019-31/2019. Monto: $ 260,000.

10. Coria Ortega Roberto. Proyecto: "Mecanismos moleculares de la participación de los reguladores de respuesta Ssk1 y Skn7 en el estrés de retículo endoplásmico en la levadura". IN210519. 01/2019-12/2019. Monto: $ 240,000.

11. Del Río Guerra Gabriel. Proyecto: "Estudio del mecanismo de acción del péptido Iztli 1 en levadura y células de mamifero". IN208817. 01/2017-12/2019. Monto: $ 140,000.

12. Dreyfus Georges. Proyecto: "Caracterización de nuevos componentes involucrados en la formación y funcionamiento de los flagelos 1 y 2 de *Rhodobacter sphaeroides*". IN 204317. 01/2017-12/2019. Monto: $ 260,000.

13. Fernández De Miguel Francisco. Proyecto: “Liberación de serotonina del cuerpo neuronal”. IN210317. 01/2017-12/2019. Monto: $ 238,618.

14. Funes María Soledad. Proyecto: "Estudio de la biogénesis mitocondrial en respuesta a cambios metabólicos y condiciones de estrés en *Saccharomyces cerevisiae*". IN207518. 01/2018-12/2020. Monto: $ 240,000.

15. Furlan Magaril Mayra. Proyecto: "Dinámica de la arquitectura genómica y accesibilidad cromatínica durante la diferenciación y maduración eritroide". IN207319. 01/2019-01/2021. Monto: $ 240,000.

16. Galarraga Palacio Elvira. Proyecto: "Papel de la transmisión GABAérgica en el circuito de los Ganglios Basales y la excitabilidad neuronal”. IN201517. 01/2017-12/2019. Monto: $ 250,000.

17. Galarraga Palacio Elvira. Proyecto: "Comparación de las oscilaciones en el potencial de membrana en neuronas corticales y en neuronas intralaminares del tálamo". IN203020. 02/2020-12/2022. Monto: $ 260,000.

18. García Sáinz Jesús Adolfo. Proyecto: "Receptores acoplados a proteínas G". IN200718. 01/2017-12/2020. Monto: $ 260,000.

19. Georgellis Dimitrios. Proyecto: Control de la expresión génica microbiana por estímulos extracelulares". IN209918. 01/2018- 12/2020 Monto: $ 240,000.

20. Gómora Martínez Juan Carlos. Proyecto: "Contribución diferencial del canal Nav1.6 y las subunidades beta de los canales Nav a las propiedades metastásicas del cáncer cervicouterino". IN206917. 01/2019-12/2019. Monto: $ 250,000.

21. González Halphen Diego. Proyecto: "Estudios topológicos y estructurales de la ATP sintasa mitocondrial de un alga clorofícea". IN208917. 01/2017-12/2019. Monto: $ 250,000.

22. González Manjarrez Alicia. Proyecto: "Diversificación e interrelación funcional de los parálogos leu4-leu9 y bat1-bat2: su influencia sobre la actividad del regulador codificado por leu3 en la levadura *Saccharomyces cerevisiae*". IN204018. 01/2018-12/2020. Monto: $ 240,000.

23. González Pedrajo Bertha. Proyecto: "Estudio del reconocimiento de sustratos de secreción en el inyectisoma de *Escherichia coli* enteropatógena". IN209617. 01/2019-12/2019. Monto: $ 240,000.

24. Guerra Crespo Magdalena. Proyecto: “Estudio del desarrollo temprano de la enfermedad de Parkinson en un modelo *in vitro* de células troncales pluripotentes inducidas provenientes de un paciente con triplicación del gen de alfa-sinucleína". IN211419. 01/2019-12/2021. Monto: $ 189,986.

25. Hansberg Torres Wilhelm. Proyecto: "Diferenciación celular como respuesta a la tensión oxidante en *Neurospora crassa*". IN208717. 01/2017-12/2019. Monto: $ 240,000.

26. Hansberg Torres Wilhelm. Proyecto: “Los mecanismos de la diferenciación celular en la formación de las esporas asexuales de *Neurospora crassa”*. IN216920. 01/2020-12/2022. Monto: $ 240,000.

27. Hernández Cruz Arturo. Proyecto: "Estudios funcionales de cardiomiocitos humanos diferenciados de células pluripotentes inducidas de sujetos normales y pacientes con síndrome de Andersen-Tawil, una cardio-canalopatía del canal de potasio Kir2.1 que cursa con arritmia y muerte súbita". IG200119. 01/2019-12/2021. Monto: $ 200,000.

28. Hernández Muñoz Rolando. Proyecto: "Caracterización de la participación de los eritrocitos en el metabolismo del nitrógeno en humanos y su posible involucramiento en la fisiopatología de enfermedades metabólicas como la diabetes tipo 2 y la cirrosis". IN203217. 02/2018-01/2019. Monto: $ 246,000.

29. Hernández Muñoz Rolando. Proyecto: “Toxicidad por la administración crónica de tres anti-retrovirales sobre el metabolismo hepático de glucosa y lípidos en la generación de esteatosis hepática en ratas”. IT200420. 11/2019-10/2020. Monto: $ 200,000.

30. Hiriart Urdanivia Marcia. Proyecto: "La insulina, el receptor soluble de insulina y el factor de crecimiento neuronal como participantes del síndrome metabólico". IN208720. 01/2020-12/2023. Monto: $ 210,000.

31. Lemus Sandoval Luis. Proyecto: "Circuitos neuronales que representan sonidos complejos en monos *Rhesus*". IN207919. 01/2019-12/2021. Monto: $ 240,000.

32. Licona Limón Paula. Proyecto: "Evaluación del papel de la cinasa PKA y de su inhibidor PKIB en el desarrollo y función de linajes linfoides productores de IL-9". IN209919. 01/2019-12/2021. Monto: $ 260,000.

33. López Colomé Ana María. Proyecto: "Regulación de la actividad de los "Receptores Activados por Proteasa (PARs)" por la calpaína en el epitelio pigmentado de la retina". IN205317. 12/2016-12/2019. Monto: $ 260,000.

34. Macías Silva Marina. Proyecto: "Regulación de los cofactores transcripcionles Ski y SnoN en hepatocitos normales y transformados". IN208118. 01/2018- 12/2020. Monto: $ 240,000.

35. Mas Oliva Jaime. Proyecto: "Proteína CETPI descrita originalmente por nuestro grupo en el IFC, como novedosa molécula marcadora en septicemia y choque séptico". IN206619. 01/2019-12/2020. Monto: $ 240,000.

36. Massieu Trigo Lourdes. Proyecto: "Respuestas al estrés energético inducido por la privación de glucose en neuronas. Dinámica mitocondrial, mitofagia y función lisosomal y su modificación por el beta-hidroxibutirato". IN204919. 01/2019-12/2021. Monto: $ 240,000.

37. Morales Lázaro Sara Luz. Proyecto: "Mecanismos moleculares que participan en la respuesta de dolor mediada por el canal TRPV1 y los receptores de estrógenos". IN206819. 01/2019-12/2019. Monto: $ 200,000.

38. Morán Andrade Julio. Proyecto: "Mecanismos de muerte y diferenciación neuronal: papel de la señalización redox". IN212019. 01/2019-12/2021. Monto: $ 240,000.

39. Navarro González Rosa. Proyecto: "El papel de los gránulos de RNA, las mitocondrias y la apoptosis en la gónada del *C. elegans*.". IN208918. 01/2019-12/2019. Monto: $ 190,000.

40. Osorio Gómez Daniel. Proyecto: “Evaluación por optogenética de la participación de la proyección amígdala-corteza insular en el establecimiento de la valencia de los estímulos”. IA201420. 01/2020-12/2021. Monto: $ 190,000.

41. Pasantes Ordóñez Herminia. Proyecto: Desarrollo de aplicaciones y dispositivos para apoyar las terapias de rehabilitación en pacientes con discapacidad neurológica”. IT200318. 01/2019-12/2019. Monto: $ 211,124.

42. Peraza Reyes Leonardo. Proyecto: "La comunicación intracelular, intercelular e ínter-reinos en los hongos". IV200519. 01/2019-12/2021. Monto: $ 375,000.

43. Pérez de la Mora Miguel. Proyecto: "Papel de la interacción entre los receptores para la oxitocina y los receptores dopaminérgicos D2 y a2 adrenérgicos en la modulación amigdalina de la ansiedad en la rata". IN205217. 01/2017-12/2019. Monto: $ 259,520.

44. Pérez Martínez Xóchitl. Proyecto: "Estudio de los mecanismos de traducción en mitocondrias de *Saccharomyces cerevisiae*". IN209217. 01/2017-12/2019. Monto: $ 250,000.

45. Ramiro Cortés Yazmín. Proyecto: “Dinámica de la actividad neuronal de corteza visual primaria en respuesta a una tarea visual de sobre-especificidad en un modelo genético de autismo (ratones SHANK3)”. IN207420. 01/2020-12/2022. Monto: $ 200,000.

46. Recillas Targa Félix. Proyecto: "Participación de RNAs no-codificantes en la regulación diferencial de los genes α-globina y en la formación de sub-dominios cromatínicos". IN203917. 01/2017-12/2019. Monto: $ 150,000.

47. Recillas Targa Félix. Proyecto: "Organización tridimensional del genoma en la regulación transcripcional del gen *Notch1* humano". IN203620. 10/2019-10/2022. Monto: $ 260,000.

48. Romo Trujillo Ranulfo. Proyecto: “Decodificación de información de más de una modalidad sensorial en las poblaciones neuronales del lóbulo frontal durante la toma de decisiones”. IN210819. 01/2019-12/2021. Monto: $ 260,000.

49. Rosenbaum Emir Tamara. Proyecto: "Caracterización de regiones que sufren cambios conformacionales ante agonistas en el canal TRPV1 por ácido lisofosfatídico". IN200717. 01/2017-12/2019. Monto: $ 250,000.

50. Rosenbaum Emir Tamara. Proyecto: "Inhibición del canal iónico TRPV4 por compuestos broncodilatadores". IN200720. 01/2020-12/2022. Monto: $ 230,000.

51. Sotres Bayón Francisco Xavier. Proyecto: "Mecanismos cerebrales que subyacen la obtención de una recompensa a pesar del peligro". IN214520. 01/2020-12/2022. Monto: $ 189,900.

52. Sotres Bayón Francisco Xavier. Proyecto: "Contribución de la neurogénesis hipocampal al regreso del miedo condicionado después de la extinción". IN205417. 01/2017-12/2019. Monto: $ 270,000.

53. Tapia Ibargüengoytia Ricardo. Proyecto: "Mecanismos de degeneración neuronal y de regeneración axonal". IN206719. 01/2019-12/2019. Monto: $ 260,000.

54. Tecuapetla Aguilar Fatuel. Proyecto: "Monitoreo óptico de la actividad de los ganglios basales durante el inicio/selección de acciones *in vivo* por medio de microendoscopios, sensores de calcio y microscopia de dos fotones". IN226517. 01/2017-12/2019. Monto: $ 240,000.

55. Torres Quiroz Francisco. Proyecto: "Modificaciones post-traduccionales en residuos de cisteína y su dinámica en *Saccharomyces cerevisiae*". IN209219. 01/2019-12/2021. Monto: $ 204,000.

56. Tovar y Romo Luis Bernardo. Proyecto: "Estudio de las respuestas moleculares de los astrocitos en la isquemia cerebral". IN226617. 01/2017-12/2019. Monto: $ 260,000.

57. Uribe Carvajal Salvador. Proyecto: "Metabolismo aerobio de la levadura y de *Wolbachia sp*". IN203018. 01/2018-12/2020. Monto: $ 200,000.

58. Valdés Víctor Julián. Proyecto: "El papel del ciclo celular y el represor epigenético Polycomb en el establecimiento, mantenimiento y perdida de la memoria metabólica inducida por alta glucosa en células troncales embrionarias (mES)". IA202118. 01/2018-12/2019. Monto: $ 200,000.

59. Velasco Velázquez Iván. Proyecto: "La influencia de factores transcripcionales, factores de crecimiento y moléculas que guían el crecimiento axonal sobre neuronas diferenciadas de células troncales embrionarias". IN213719. 01/2019-12/2021. Monto: $ 255,000.

60. Velasco Torres Myrian. Proyecto: "Análisis funcional de los canales de potasio sensibles a ATP en el síndrome metabólico". IN210118. 01/2018-12/2019. Monto: $ 180,000.

Proyectos Financiados por CONACyT

1. Bargas Díaz José. Proyecto: "CONACyT Fronteras". "Estructura funcional de un microcircuito cortical". Fronteras-57. 17/2017-17/2019.

2. Bermúdez Rattoni Federico. Proyecto: "Estudio de la consolidación, evocación y actualización de la memoria. Mecanismos Neurobiológicos y sus implicaciones en procesos neuropatológicos". Ciencia Básica 250870. 2016-2019. Monto: $ 1,500,000.

3. Bermúdez Rattoni Federico. Proyecto: "La corteza insular como nuevo blanco para estudiar los mecanismos celulares de la formación y mantenimiento de las memorias adictivas". Fronteras de la Ciencia 474. 2015-2019. Monto: $ 4,000,000.

4. Bermúdez Rattoni Federico. Proyecto: "Proyecto de Investigación en colaboración Franco-Mexicano". OBETEEN. 2016-2020. Monto: € 500,000.

5. Castro Obregón Susana. Proyecto: "Probando la hipótesis de que en el envejecimiento fisiológico emergen nichos para el desarrollo de enfermedades crónicas". Fronteras 015-2#921. 12/2016-10/2019. Monto: $ 3,000,000.

6. Coria Ortega Roberto. Proyecto: "Papel de las proteínas G en la respuesta al estrés de retículo endoplásmico en levaduras". 254078. 07/2018-07/2019. Monto: $ 315,000.

7. Dreyfus Cortés Georges. Proyecto: "Estudio sobre la regulación de la expresión del sistema flagelar 2 en *Rhodobacter sphaeroides*". 235996. 07/2015-02/2019. Monto: $ 430,000.

8. Escalante Alcalde Diana. Proyecto: "La LPP3, una enzima reguladora de la actividad de lípidos bioactivos, como enzima fundamental para el desarrollo del sistema nervioso y en la neurogénesis adulta". CB-250613. 11/2016-10/2019. Monto: $ 560,000.

9. Galarraga Palacio Elvira. Proyecto: "Caracterización funcional de la vía tálamo estriatal". 251144. 08/2017-07/2020. Monto: $ 450,000.

10. García Sáinz Jesús Adolfo. Proyecto: "Regulación de la función de receptores acoplados a proteínas G". 253156. 07/2017-06/2019. Monto: $ 500,000.

11. Gómora Martínez Juan Carlos. Proyecto: "Bases moleculares y funcionales en la modulación de canales de calcio tipo T de humano por compuestos estructuralmente diversos". A1-S-19171. 09/2019-09/2022. Monto: $ 666,000.

12. González Halphen Diego. Proyecto: "Hacia la cristalización de una atp sintasa mitocondrial dimérica: efectos de un detergente de nueva generación derivado del lauril-maltósido". 279125. 01/2017-12/2020. Monto: $ 20,000.

13. González Pedrajo Bertha. Proyecto: "Regulación de la secreción de proteínas a través del inyectisoma de *Escherichia coli* enteropatógena: estudio del reconocimiento y jerarquización de sustratos". 284081. 06/2018-06/2021. Monto: $ 666,000.

14. Guerra Crespo Magdalena. Proyecto: "Desarrollo de una nueva estrategia de diferenciación de células troncales pluripotentes humanas trasplantadas en un modelo de enfermedad de Parkinson". A1-S-10064. 10/2019-09/2021. Monto: $ 858,387.

15. Hernández Cruz Arturo. Proyecto: "Laboratorio Nacional de Canalopatias consolidacion III". 299051. 05/2019-11/2019. Monto: $ 1,500,000.

16. Lemus Luis. Proyecto: "Procesamiento de información rio-arriba y rio-abajo en el circuito audiomotor durante el seguimiento del ritmo de un metrónomo en primates humanos y no-humanos". Fronteras de la Ciencia 196. 06/2015-06/2019. Monto: $ 800,000.

17. Lemus Luis. Proyecto: "Codificación Neuronal de Objetos Auditivos". 256767. 01/2016-01/2019. Monto: $ 498,700.

18. Licona Limón Paula. Proyecto: "Mecanismos moleculares en el control de la diferenciación de los linajes linfoides: regulación por la citocina TGF-β y la cinasa PKA". 255287. 07/2016-07/2019. Monto: $ 685,000.

19. López Casillas Fernando. Proyecto: "Análisis genético reverso (CRISPR-Cas9) de la función del Betaglicano en el desarrollo embrionario del pez cebra". 254046. 01/2019-02/2020. Monto: $ 500,000.

20. López Colomé Ana María. Proyecto: "La trombina como agente inductor de gliosis en la retina". 254333. 10/2016-10/2019. Monto: $ 1,370,000.

21. Luis Baltazar Enoch. Proyecto: "El cancer como canalopatia: identificación y caracterización de nuevos compuestos con efecto modulador sobre canales oncogénicos de K^+". A1-S-13646. 01/2019-01/2020. Monto: $ 376,308.

22. Mas Oliva Jaime. Proyecto: "Estudio de correlación estructura/función de CETPI como una nueva proteína de unión a lipopolisacáridos bacterianos". 255778. 06/2016-07/2019. Monto: $ 660,000.

23. Massieu Trigo Lourdes. Proyecto: "Pérdida de la proteostasis por la privación y reintroducción de glucosa en neuronas, su papel en la muerte neuronal y su posible restablecimiento por acción del β-hidroxibutirato". CB A-1S-17357. 11/2019-11/2020. Monto: $ 507,333.

24. Morán Andrade Julio. Proyecto: "Señalización redox en el desarrollo neuronal: papel en la muerte neuronal y el crecimiento axonal". 285184. 06/2018-06/2021. Monto: $ 1,800,000.

25. Navarro González Rosa. Proyecto: "Mecanismos de regulación de la respuesta al estrés de las células germinales del nematodo *Caenorhabditis elegans*". 220987. 03/2015-06/2019. Monto: $ 500,000.

26. Peña Díaz Antonio. Proyecto: "Efectos de agentes catiónicos, sal y pH sobre *Saccharomyces cerevisiae* y *Debaryomyces hansenii*. Cultivo de metabolismo y bioenergética de *Wolbachia pipientis*" 238497. 07/2016-09/2019. Monto: $ 600,000.

27. Peraza Reyes Leonardo. Proyecto: "Crosstalk between peroxisomes, endoplasmic reticulum, and endosomes during polar growth and development in fungi". 277869. 03/2018-02/2021. Monto: $ 803,000.

28. Pérez Martínez Xochitl. Proyecto: "Estudio de los mecanismos de acoplamiento entre la síntesis de proteínas mitocondrial y citosólica". 284514. 02/2018-02/2020. Monto: $ 908,000.

29. Pérez Montfort Ruy. Proyecto: "Estudios en enfermedades humanas de la triosafosfato isomerasa". 254694. 10/2016-02/2020. Monto: $ 500,000.

30. Ramiro Cortés Yazmín. Proyecto: "Plasticidad sináptica y estructural en un modelo de autismo". 254878. 09/2016-08/2019. Monto: $ 412,500.

31. Recillas Targa Félix. Proyecto: "La organización tridimensional de genoma en la regulación de la expresión génica". Fronteras de la Ciencia 2015-290. 01/2017-12/2019. Monto: $ 2,000,000.

32. Recillas Targa Félix. Proyecto: "Papel del factor nuclear CTCF y RNAs no-codificantes en la regulación de la expresión génica y la estructura de la cromatina". 220503. 03/2017-02/2018. Monto: $ 500,000.

33. Recillas Targa Félix. Proyecto: "Regulación epigenética y transcripcional de dos RNAs largos no codificantes divergentes en líneas de cáncer de mama". CONACyT Básica A1-S-11844. 09/2018-08/2021. Monto: $ 1,900,000.

34. Rosenbaum Emir Tamara. Proyecto: “Regulación del canal TRPV4 por fosfolípidos ". A1-S-8760. 01/2019-01/2021.

35. Sotres Bayón Francisco. Proyecto: "Previniendo el regreso del miedo: contribución de la neurogénesis hipocampal". 2463. 05/2018-05/2020. Monto: $ 1,500,00.

36. Tapia Ibargüengoytia Ricardo. Proyecto: "Mecanismos celulares de la degeneración y regeneración neuronal". A1-S-12135. 09/2019-08/2020. Monto: $ 560,000.

37. Tecuapetla Aguilar Fatuel. Proyecto: "Optogenética: visualización y evaluación de los subcircuitos del control motor *in vivo*". Fronteras de la Ciencia 2022. 10/2017-10/2019. Monto: $ 200,000.

38. Torres Larios Alfredo. Proyecto: "Estudios estructurales sobre complejos ribonucleoproteicos". CB2015-253323. 06/2016-06/2019. Monto: $ 800,000.

39. Tovar y Romo Luis Bernardo. Proyecto: "Regulación trófica de la viabilidad neuronal; mecanismos endógenos de recuperación después del infarto cerebral isquémico". A1-S-13219. 10/2019-10/2022. Monto: $ 500,000.

40. Valdés Víctor Julián. Proyecto: "Papel de la epigenética en circuitos neuronales involucrados en conducta de *Caenorhabditis elegans*". 284867. 01/2018-12/2020. Monto: $ 500,000.

41. Velasco Velázquez Iván. Proyecto: "Diferenciación de células troncales pluripotenciales humanas a neuronas dopaminérgicas para generar modelos celulares de la enfermedad de parkinson y realizar estudios pre-clínicos de trasplante". 272815. 12/2016-05/2020. Monto: $ 3,000,000.

42. Velasco Velázquez Iván. Proyecto: "Diferenciación dopaminérgica de células troncales: estudios de crecimiento axonal y superviviencia en ratas que modelan la enfermedad de Parkinson". CB15-256092. 07/2016-06/2019. Monto: $ 1,500,000.

43. Velasco Velázquez Iván. Proyecto: "Estudios de secuenciación masiva y proteómica para la identificación de reguladores moleculares de la regeneración posterior al daño en la médula espinal del ajolote. Convocatoria bilateral CONACyT-Tubitak (Turquía) del Fondo CONACyT-Secretaría de Relaciones Exteriores". 265793. 12/2017-04/2020. Monto: $ 1,735,000.

44. Velasco Velázquez Iván. Proyecto: "Liberación de factores quimioatrayentes para axones dopaminérgicos humanos por nanoesferas vacías de dióxido de Titanio". UC-MEXUS CN 19-163. 07/2019-12/2020. Monto: 25,000 USD.

Proyectos Financiados por Otras Empresas de Gobierno Federal y Local

1. Castro Obregón Susana. Proyecto: “Investigación sobre el potencial papel terapéutico de inducir la autofagia con una combinación de ayuno intermitente, dieta cetogénica e ingesta de trehalosa para aminorar síntomas relacionados al envejecimiento". INGER-DI-CRECITES-008-2018. 11/2018-10/2019. Monto: $ 1,292,760.

2. Mas Oliva Jaime. Proyecto: "Secretaría de Desarrollo Institucional (UNAM). Supercómputo (MIZTLI)". LANCAD-UNAM-DGTIC-352. 02/2019-12/2019. Monto: $ 153,000.

3. Massieu Trigo Lourdes. Proyecto: "Potencial papel terapéutico de inducir la autofagia con una combinación de ayuno intermitente, dieta cetogénica e ingesta de trehalosa para aminorar síntomas relacionados al envejecimiento fisiológico y la enfermedad de Alzheimer. Resp. S. Castro". INGER-DI-CRECITES-008-2018. 11/2018-11/2019. Monto: $ 1,292 760.

4. Rosenbaum Emir Tamara. Proyecto: "Potenciales blancos terapéuticos para evitar la progresión de daño renal en la enfermedad poliquística del adulto". 9625c19. 01/2020-12/2020. Monto: $ 1,000,000.

5. Salceda Sacanelles Rocío. Proyecto: "Red Colaborativa de Investigación Traslacional para el Envejecimiento Saludable de la Ciudad de México". INGER-DI-CRECITES-006-2018. 10-2018/10-2019. Monto: $ 375,000.

Proyectos Financiados por Organismos y Empresas Nacionales

1. Chagoya de Sánchez Victoria. Proyecto: "Vela Advisor SA". CIE 1407279. 01/2019-12/2019. Monto: $ 1,500,000.

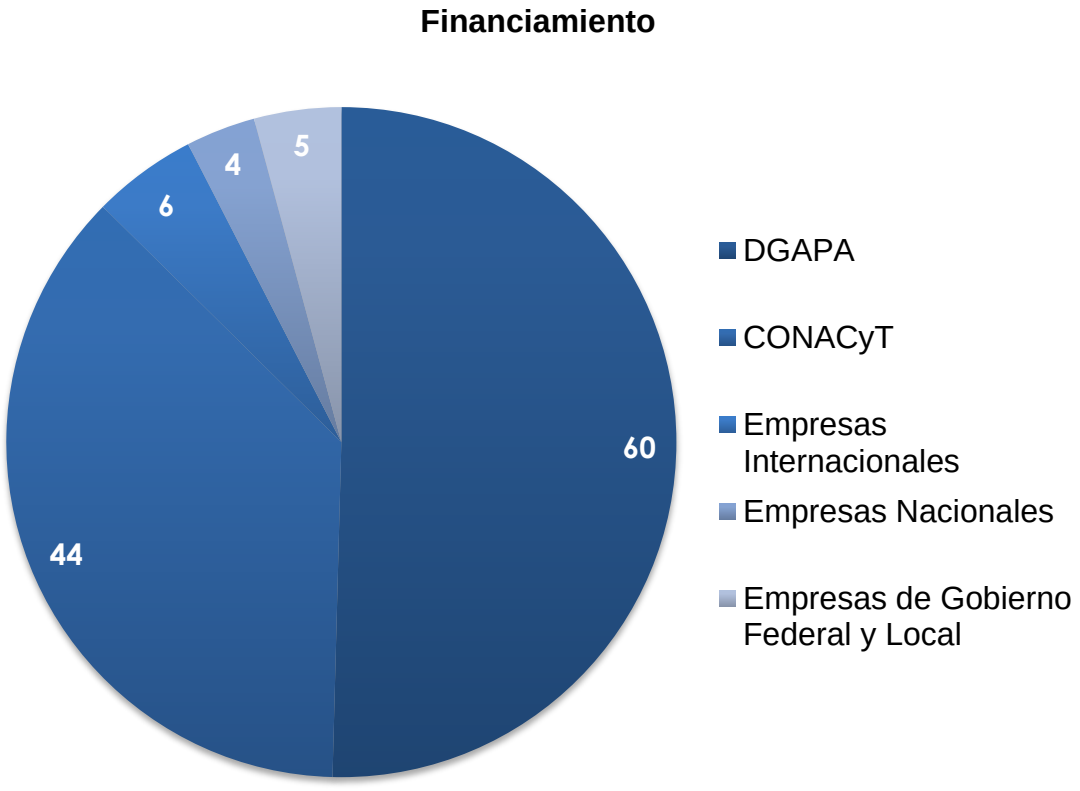
2. Mas Oliva Jaime. Proyecto: "Estímulo a la Investigación Médica, Miguel Alemán Valdés”. 01/2019-12/2019. Monto: $ 100,000.

3. Recillas Targa Félix. Proyecto: "Estímulo a la Investigación Médica, Miguel Alemán Valdés”. 12/2018-12/2019. Monto: $ 100,000.

4. Valdés Rodriguez Víctor Julián. Proyecto: "Premio Ruben Lisker 2018". 4ta edición. 11/2018-11/2020. Monto: $ 1,000,000.

Proyectos Financiados por Organismos y Empresas Internacionales

1. Bermúdez Rattoni Federico. Proyecto: "Transcriptional signatures of cognitive decline in an Alzheimer´s disease model". The Royal Society. 07/2017-07/2019. Monto: £11,953.



2. Del Río Guerra Gabriel. Proyecto: "Alexander von Humboldt foundation. Study of anastasis in yeast". 06/2019-12/2019. Monto: $ 400,000.

3. Fernández De Miguel Francisco. Proyecto: "Human Frontiers Science Program". RGP0060/2019. 07/2019-06/2021. Monto: 110,000 USD.

4. Fernández De Miguel Francisco. Proyecto: "Society for Neuroscience". 2019-3276. 08/2019. Monto: 70,000 USD.

5. Licona Limón Paula. Proyecto: "Unión Iberoamericana de Universidades. Second Research Collaboration Fund 2019.". USP-05-2019. 09/2019-08/2020. Monto: 2,000 USD.

6. Tovar y Romo Luis Bernardo. Proyecto: "Committee for Aid and Education in Neurochemistry - International Society for Neurochemistry". Cat 1B. 10/2019-09/2020. Monto: 4,500 USD.

CONVENIOS E INTERCAMBIOS

Convenios Suscritos por Personal del IFC

1. Bermúdez Rattoni Federico. Efectuado con: Francia (ANR)-México (CONACyT). Proyecto: Evaluación de daños cognitivos en animales jóvenes sometidos a dietas hipercalóricas. De investigación. Fecha: 2016-2020. Financiado por: CONACyT. Monto: € 500,000.

2. Gómora Martínez Juan Carlos. Efectuado con: Dr. Sebastien Roger. Proyecto: Pharmacological and nutritional targeting of voltage-gated sodium channels in the treatment of epithelial cancers. Fecha: 09/2017-08/2019. Financiado por: Le Studium Research Consortium.

3. Hernández Cruz Arturo. Efectuado con: Centro Universitario de Investigaciones Biomédicas de la Universidad de Colima. Proyecto: Laboratorio Nacional de Canalopatías (consolidación III), Participación como Unidad Asociada. De investigación. Fecha: 06/2019-12/2019. Financiado por: CONACyT. Monto: $ 1,500,000.

4. Hernández Cruz Arturo. Efectuado con: Instituto de Ciencias del Mar y Limnologia, UNAM. Proyecto: Laboratorio Nacional de Canalopatías (Consolidación III). Participación como Unidad Asociada de Investigación. Fecha: 06/2019-11/2019. Financiado por: CONACyT. Monto: $ 1,500,000.

5. Hernández Cruz Arturo. Efectuado con: CINVESTAV Unidad Monterrey. Proyecto: Laboratorio Nacional de Canalopatías (Consolidación III). Participación como Unidad Asociada. De investigación. 06/2019-11/2019. Financiado por: CONACyT. Monto: $ 1,500,000.

6. Hernández Cruz Arturo. Efectuado con: Facultad de Química/Unidad de Investigación Preclínica. Proyecto: para llevar a cabo de manera conjunta actividades en materia de investigación, desarrollo tecnológico, estancias de investigación, proyectos científicos, formación y capacitación de recursos humanos. De investigación. Fecha: 08/2018-08/2022.

7. López Colomé Ana María. Efectuado con: Dr. Luis Fernando Hernández Zimbrón. Proyecto: Desarrollo y aplicación de materiales avanzados en la producción de Bio-Membranas artificiales funcionales para su uso en medicina traslacional: DMRE (MEMBRANAS V1 090818). Financiado por: Asociación para evitar la ceguera en México, IAP.

8. Rossi Pool Román. Efectuado con: Dr. Nestor Parga Carballeda. Proyecto: Performance, behavioral biases and confidence in the two-interval forced-choice paradigm. De investigación. Fecha: 10/2018-10/2021. Financiado por: ANPCYT - Madrid, España.

9. Tovar y Romo Luis Bernardo. Efectuado con: Dr. Nigel H Greig. Proyecto: Single cell transcriptomics of microglial responses to traumatic brain injury. De investigación. Fecha: 07/2019-09/2019.

10. Velasco Velázquez Iván. Efectuado con: Instituto Nacional de Neurología y Neurocirugía "Manuel Velasco Suárez" (INNN-MVS). Proyecto: Convenio para continuar con el funcionamiento del Laboratorio de Reprogramación Celular del Instituto de Fisiología Celular-UNAM en el INNN-MVS. Convenio con número de registro 48955-1771-25-VII-17. 11/2017-11-2020.

UNIDADES DE SERVICIO

Unidad de Biología Molecular

Responsable:

Laura María Ongay Larios, Dra.	**Técnico Académico Titular C. PRIDE D. SNI I.**
María Guadalupe Códiz Huerta, Biól.	Técnico Académico Titular B. PRIDE C.
Dolores Minerva Mora Cabrera, M. en C.	Técnico Académico Titular B. PRIDE C.

En esta unidad se ofrecieron los siguientes servicios técnicos:

- Síntesis de oligonucleótidos.
- Secuenciación capilar automatizada.
- Tipificación de fragmentos por electroforesis capilar.
- Secuenciación masiva (NGS).
- Purificación de DNA.
- Clonación de DNA.
- Analizadores de muestras marcadas con radioactividad, quimioluminiscencia o quimiofluorescencia.
- PCR en tiempo real.
- Analizador de imágenes.
- Electroforesis en campo ortogonal.
- Termocicladores.
- Citómetro de flujo.
- Espectrofotómetro
- Banco de plásmidos y cepas bacterianas.

Durante 2019 se sintetizaron 897 oligonucleótidos con un total de 24,542 bases (usuarios internos 613 oligonucleótidos (16,089 bases), usuarios externos 244 oligonucleótidos (17,809 bases), usuarios externos 284 oligonucleótidos (6,733 bases). Algunos oligonucleótidos fueron purificados por PAGE. El servicio fue utilizado por 28 grupos de investigación del instituto, 6 dependencias de la UNAM y 11 fuera de la UNAM. También se secuenciaron plásmidos,

cósmidos, productos de PCR, se realizaron 2,101 secuencias (servicio interno 1,307 reacciones, servicio externo 794). Se realizó la electroforesis de 273 reacciones listas para correr (servicio interno 20 reacciones, externo 253). El servicio de secuenciación fue utilizado por 26 grupos de investigación del instituto, 7 por dependencias de la UNAM y 14 de fuera de la UNAM. En este año se corrieron 16 análisis de fragmentos para análisis de Fragile X. Se purificaron 26 productos de PCR, el servicio fue usado por 2 grupos de investigación fuera de la UNAM. En 2019 se realizaron 208 “scans”, este servicio fue utilizado por 5 grupos de investigación de este Instituto. Se llevaron a cabo 338 corridas de PCR en tiempo real. El 92% fueron realizadas por 16 grupos de investigación del IFC, y el 8% por 4 grupos de investigadores de otras dependencias de la UNAM y uno externo. El Analizador de imágenes fue utilizado 530 veces por 25 grupos de investigación de este Instituto. En los Termocicladores el servicio fue utilizado por 18 grupos de investigación del IFC. En el Citómetro de flujo se hicieron un total de 91 corridas de citrometría y el servicio fue utilizado por 10 grupos de investigación del IFC. Los equipos de Espectrofotómetro fueron utilizados 1,054 veces por grupos de investigación del IFC y 1 de una dependencia de la UNAM. Los bancos de plásmidos y cepas bacterianas de uso común en técnicas de Biología Molecular se han mantenido y actualizado.

Asesoría y apoyo técnico. La unidad proporcionó asesoría y entrenamiento a estudiantes, técnicos e investigadores en diferentes técnicas de Biología Molecular como purificación de DNA mitocondrial y nuclear, purificación de plásmidos, productos de PCR, amplificación de secuencias de DNA y RNA mediante las técnicas de PCR y RT-PCR, clonación de DNA en sistemas bacterianos, análisis de DNA recombinante, análisis de patrones de restricción, electroforesis en geles de agarosa y acrilamida, electroforesis en campo ortogonal, hibridaciones tipo Southern, “Dot Blot” y Northern, marcaje de sondas, análisis de oligonucleótidos en geles de acrilamida, purificación de RNA total y mensajero. Así como asesoría y entrenamiento en secuenciación capilar automatizada de DNA y secuenciación de siguiente generación (NGS). En 2019 la Unidad recibió 32 agradecimientos; tanto para la unidad como individuales, 17 agradecimientos en 8 artículos internacionales y 24 en tesis (2 de licenciatura, 8 de maestría y 14 de doctorado). Así como 1 publicación en 1 artículo internacional. Se impartieron 8 cursos en la UNAM y se asistió a diversas reuniones académicas.

Comisión de la Unidad de Biología Molecular:

Dra. Mayra Furlan Magaril
Biól. Gustavo Sánchez Chávez
Dra. Laura Ongay
Dr. Luis Tovar y Romo
Secretaria Ejecutiva: Dra. Susana Castro

Unidad de Cómputo

Responsable:

José Gerardo Coello Coutiño, Biól.	**Técnico Académico Titular C. PRIDE D.**
Ana María Escalante Gonzalbo, M. en C.	**Técnico Académico Titular C. PRIDE D.**
Juan Manuel Barbosa Castillo, Ing.	Técnico Académico Titular A. PRIDE C.
Francisco Pérez Eugenio, Lic.	Técnico Académico Titular A. PRIDE D.
Ivett Rosas Arciniega, Ing.	Técnico Académico, Asociado C. PRIDE B.
Pablo Rangel Silva, Méd. Cir.	Técnico Académico Titular A. PRIDE B.
Yoas Saimon Ramírez Graullera, Lic.	Técnico Académico, Asociado C. PRIDE B.

La unidad de Cómputo es responsable del mantenimiento, implementación y desarrollo de todos los recursos de cómputo generales del IFC. Esto incluye mantenimiento de servidores, comunicaciones, videoconferencia, páginas de internet, herramientas de bioinformática mantenimiento y actualización de equipos, así como el soporte técnico a los miembros de la comunidad. Así mismo da asesoría a los usuarios del instituto y a externos, imparten cursos y preparan personal en el área, quienes realizan su servicio social y sus tesis. También se administra el servicio de videoconferencia.

En 2019 se supervisó y se llevaron a cabo trabajos de canalización, cableado e instalación de equipos de comunicación de la nueva red de datos del Instituto. Se configuraron los equipos de comunicación y se instalaron en cada uno de los 14 closets de datos para la nueva red. Se instaló el nuevo firewall de red, se configuraron las reglas de acceso y migración de las reglas de otros 2 firewall que funcionaban con la antigua red. Se realizó la migración de todas las cuentas de correo electrónico del IFC del servidor Zimbra a una cuenta institucional de Gmail. Se administró, actualizó y monitoreó de los más de 30 servidores de red que hay en el Instituto. También se llevó a cabo el mantenimiento correctivo de varios equipos del IFC. También se apoyó en la transmisión por streaming, grabación y almacenamiento de cursos y seminarios dictados por videoconferencia. Se brindó apoyo de videoconferencia para la impartición de 8 cursos de posgrado con Institutos de la UNAM y para la realización de 142 exámenes tutorales, 24 de grado y 16 candidaturas. Se llevaron a cabo enlaces de videoconferencia para la transmisión de más de 65 seminarios institucionales. Se realizaron 40 enlaces de videoconferencias para reuniones de trabajo, comisiones dictaminadoras y juntas de diversa índole. Se actualizó el programa del Informe de labores del IFC. Se impartieron 3 cursos de Licenciatura en la Facultad de Ingeniería. La Unidad recibió 4

agradecimientos en artículos internacionales, 1 agradecimiento en tesis de licenciatura, 1 de maestría y 5 de doctorado. Se brindó apoyo logístico al Laboratorio de Neuro-Rehabilitación que participó en diversas actividades académicas.

Comisión de la Unidad de Cómputo:
Dr. Luis Lemus Sandoval
M.I. Manuel Tonatiuh Figueroa Vanegas
Dra. Xóchitl Pérez Martínez
Dr. Marcelino Arciniega
Biól. Gerardo Coello
Secretario Ejecutivo: Dr. Diego González Halphen

Imagenes de la Nueva Red de Computo del IFC

Unidad de Imagenología

Responsable:

Ruth Rincón Heredia, Dra.	**Técnico Académico Asociado C. PRIDE B. SNI I**
Rodolfo Paredes Díaz, Méd. Cir.	Técnico Académico Titular A. PRIDE C.
Abraham Rosas Arellano, Dr.	Técnico Académico Titular B. SNI I.
Nicolás Jimenez Pérez, Dr.	Técnico Académico Titular B. PRIDE C.

Página de internet:
https://sites.google.com/email.ifc.unam.mx/imagenologa-ifcunam/p%C3%A1gina-principal

La unidad provee el acceso a tecnología de punta, en el área de microscopia a estudiantes e investigadores del Instituto de Fisiología Celular y otras dependencias de la UNAM, e instituciones externas, así como a la industria. De manera general la Unidad de Imagenología se divide en dos grandes ramas de la microscopia: 1) la microscopía fotónica y 2) la microscopía electrónica. Es también función de la unidad apoyar la divulgación de las investigaciones que se llevan a cabo en el Instituto, por medio de la participación en congresos especializados en el área y en recibir visitas guiadas de estudiantes de nivel superior.

Actividades realizadas en 2019:

- En el área de microscopía electrónica de barrido y transmisión se procesaron un total de 77 muestras epon, 12 muestras para tinción negativa y 3 muestras para inmunogold, para diferentes grupos de investigación del Instituto. Se atendieron un total de 176 horas en el Microscopio Electrónico de Transmisión.
- La microscopía electrónica de barrido se atendieron un total de 20 usuarios, también se procesaron 2 muestras recubiertas de oro. El personal también participó en 3 publicaciones científicas internacionales. El trabajo de la unidad fue reconocido con agradecimientos en 12 publicaciones científicas, en 2 agradecimientos en tesis de licenciatura, 16 de maestría y 6 de doctorado. También se recibieron 2 visitas guiadas.

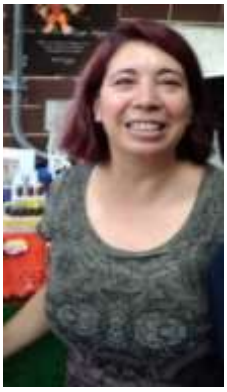
Comisión de la Unidad de Microscopía (Imagenología):

Dr. Luis Vaca Domínguez
Dra. Yazmín Ramiro Coirtés
Dra. Ruth Rincón Heredia
Dr. Miguel Tapia (externo, Biomédicas)
Secretaria Ejecutiva: Dra. Diana Escalante

Laboratorio Nacional De Canalopatías

Laboratorio Nacional de Canalopatías

Responsable:



Arturo Hernández Cruz, Dr. — **Investigador Titular C. PRIDE D. SNI III.**
Arturo Picones Medina, Dr. — Técnico Académico Titular A. PRIDE B.
Enoch Luis Baltazar, Dr. — Catedrático CONACyT.
Arlet del Carmen Loza Huerta, Dra. — Técnico Especializado por honorarios.Cand. SNI.
César Oliver Lara Figueroa, Fís. — Técnico Especializado por honorarios.

En el Laboratorio Nacional de Canalopatías (LaNCa) se brindan servicios de citometría de flujo, fluorometría, electrofisiología e imagenología automatizada, a grupos de investigación del Instituto, así como de la UNAM y fuera de ella y también a sus instituciones asociadas.

Cuenta con equipamiento automatizado para ensayos electrofisiológicos y fluorométricos y de citometría de flujo rápidos y de alto rendimiento, así como el registro electrofisiológico tradicional (manual), que sigue siendo el “gold estándar” para validar resultados.

Durante el año 2019 el LaNCa participó en 3 actividades de difusión y divulgación, participó en 2 reuniones académicas nacionales y 2 internacionales; así como en congresos nacionales e internacionales. Se publicaron 5 artículos internacionales en revistas indizadas. También recibieron 2 agradecimientos en publicaciones internacionales. Se graduaron 3 estudiantes de licenciatura. Se dictaron 6 cursos de licenciatura y se participó en 6 actividades de apoyo a la docencia.

Coordinación de Difusión Y Divulgación

Responsable:

Luz Lazos, Dra. — **Técnico Académico Titular B. PRIDE B.**
Ana Cecilia Rosen Ferlini, Dra. — **Técnico Académico Titular B. PRIDE B. Cad. SNI.**
Felipe Zenil Ongay, M. en C. — Técnico Especializado por honorarios.

En esta Coordinación se diseña, planea y coordinan las actividades para la divulgación de las investigaciones en ciencias biológicas y neurociencias del Instituto. También se incluyen aspectos como el diseño de materiales educativos y de comunicación dirigido a profesores, estudiantes y público en general, en versiones impresas y digitales, la planeación y diseño de cursos presenciales y a distancia para profesores. También la vinculación con diferentes dependencias universitarias para la colaboración en proyectos conjuntos de comunicación, educación, arte y cultura. Durante el año 2019 se participó en diferentes eventos de difusión de la ciencia en la UNAM y fuera de ella, se diseñaron carteles para la difusión de los eventos académicos que se llevaron a cabo en el IFC y su adaptación para los distintos formatos con son: web, pantallas del IFC y redes sociales. Se elaboraron notas informativas diversas. Se apoyó en la coordinación a los investigadores que participaron en diferentes charlas y se coordinaron las visitas guiadas de Jóvenes hacía la Investigación.

Comisión de Difusión y Divulgación:

Dra. Soledad Funes
M. en C. Blanca Delgado
Dra. Gabriela Loyden
Secretaria Ejecutiva: Dra. Herminia Pasantes

Biblioteca “Armando Gómez Puyou”

Responsable:

Sandra G. Moncada Hernández, Mtra. — **Técnico Académico Titular B. PRIDE C.**
Javier Gallegos Infante, Cir. Dent. — Técnico Académico Titular B. PRIDE C.

Durante el año 2019 la Biblioteca contó con el siguiente acervo bibliográfico y hemerográfico: 58 libros adquiridos para acervo, 199 suscripciones a publicaciones periódicas vigentes, 3 suscripciones de publicaciones periódicas impresas y además 3 libros adquiridos para el personal académico.

Servicios Bibliotecarios:
Consulta Electrónica. Se apoyó a los usuarios tanto internos como externos, en los servicios de información generados por la biblioteca (catálogo electrónico de las colecciones bibliográfica y hemerográfica), de la Dirección General de Bibliotecas y de otras fuentes de información, así como también realizando búsquedas en fuentes especializadas. Tanto el personal académico como los bibliotecarios asisten a los usuarios a través de asesorías u orientación en el uso de estas herramientas de búsqueda.

En 2019 se apoyó en los servicios de información electrónicos, como catálogo electrónico de las colecciones bibliográfica y hemerográfica. También se adquirió bibliografía para la Licenciatura en Neurociencias. Se asesoró a los usuarios internos y externos para el uso eficiente de los recursos de información electrónica. Se recibieron agradecimientos en tesis: 1 de licenciatura, 3 de maestría y 3 de doctorado. Se atendieron 15 solicitudes de búsquedas de citas, en las diferentes bases de datos especializados, 11 para usuarios del IFC y 4 externos.

Comisión de la Biblioteca:

Dra. Rosa Navarro
Dr. Julián Valdés
Odont. Javier Gallegos
Mtra. Sandra Moncada
Secretario Ejecutivo: Dr. Raúl Aguilar

Bioterio

Responsable:

Claudia V. Rivera Cerecedo, MVZ — **Técnico Académico Titular C. PRIDE D.**
Héctor Alfonso Malagón Rivero, MVZ — Técnico Académico Titular A. PRIDE C.
Gabriela X. Ayala Méndez, M. en IBB — Técnico Académico Titular B. PRIDE C.

En el bioterio se llevan a cabo actividades relacionadas con el cuidado de animales para experimento. Durante el 2019 se cumplieron los requerimientos de animales para los protocolos aprobados por el CICUAL. El promedio en producción al año de ratas (*Ratus norvergicus)* fue de 3,682. Una de las actividades más importantes de esta unidad es brindar apoyo a los investigadores y estudiantes de posgrado que utilizan animales en sus protocolos de investigación. Durante este año, 88 protocolos de los 156 que fueron aprobados por el CICUAL permanecieron vigentes. En 2019 se utilizaron 6,933 *Ratus norvergicus,* 8,066 *Mus musculus* y 12 *Oryctolagus cuniculus.* Además de dar mantenimiento a los animales en fase experimental. En el año 2019 los investigadores de otras instituciones de la UNAM y fuera de ella, continuaron adquiriendo roedores producidos en el bioterio de este Instituto. Durante 2019, el personal académico impartió y asistió a diversos cursos. Se impartieron 4 asesorías sobre diferentes temas relacionados con la ciencia de los animales, 5 cursos talleres teórico práctico de manejo de roedores de laboratorio. También se impartió el curso de Cirugía Básica en Roedores. En este año 1 alumno concluyó su servicio social.

Comisión del Bioterio (CICUAL):

Dra. Paula Licona
MVZ. Claudia Rivera
Dr. Fatuel Tecuapetla
Dra. Rocio Alcántara
Secretaria Ejecutiva: Dra. Diana Escalante

Taller de Mantenimiento

Responsable:
Aurey Galván Lobato, Ing. **Técnico Académico Titular C. PRIDE C.**
Manuel Ortínez Benavides, Ing. Técnico Académico Titular B. PRIDE C.

En esta área se realizan labores de mantenimiento correctivo y preventivo al equipo de investigación, así como también apoyar las necesidades de los investigadores que requieren mantenimiento correctivo y preventivo a sus equipos. Se diseñan y construyen equipos totales o partes de los mismos, para su uso en los diferentes laboratorios de investigación.

Durante 2019 se atendieron un total de 300 solicitudes de servicio, incluyendo 218 de pipetas; para el Instituto. También algunas solicitudes de fabricación de piezas de acuerdo a los requerimientos de los usuarios. Se llevó a cabo el mantenimiento a las subestaciones eléctricas y autoclaves. Se tiene un programa preventivo constante y correctivo, para las centrífugas de piso de todas las áreas comunes que se tienen en el Instituto y para las máquinas fabricadoras de hielo, cuartos de temperatura controlada, refrigeradores y agitadores de cultivo. Se dio supervisión en el funcionamiento de los sistemas de agua desionizada. Durante este periodo se obtuvieron agradecimientos en 3 publicaciones internacionales; así como también en 3 tesis de doctorado y 1 de maestría. También se participó en dos cursos.

Además se apoya al Departamento de mantenimiento del IFC, en asesoría técnica, supervisión de trabajos con personal interno y externo, además de la planeación de mejoras en equipo e inmueble, en coordinación con el Departamento de Servicios Generales del Instituto de Fisiología Celular.

Comisión de Taller de Mantenimiento:

M. I. Bruno Méndez Ambrosio
Dr. Jesús Alvarez López
Dr. Fernando Suaste Olmos
Secretario Ejecutivo: Dr. Jorge Ramírez

Unidad de Histología

Responsable:
Ma. Teresa Guadalupe Cortés Flores, Lic. **Honorarios.**
Sandra Daniela Rodríguez Montaño, Lic. Técnico Académico Asociado A. PRIDE B.

Esta unidad apoya las labores de investigación del Instituto de Fisiología Celular. Cuenta con el servicio de procesamiento de muestras histológicas para microscopía de luz, utilizando las técnicas de cortes en parafina y cortes por congelación, se realizan también las diferentes tinciones en cortes hechos en las técnicas de parafina y congelación, preparación de diferentes soluciones, utilizando reactivos y colorantes para las diferentes técnicas histológicas. Durante 2019 se atendieron un total de 152 solicitudes. Se recibió 1 agradecimiento en 1 publicación internacional y se participó en 2 reuniones académicas.

Comisión de la Unidad de Histología:

Biól. Teresa Montiel
Dra. Rocío Salceda
Dra. Leticia Ramírez Lugo
Secretario Ejecutivo: Dr. Julio Morán

Unidad de Servicio de Microarreglos de ADN de la UNAM

Responsable:

Jorge Ramírez Salcedo, Dr.	**Técnico Académico Titular C. PRIDE D. SNI I**
Lorena Chávez González, Lic.	Técnico Académico Titular A. PRIDE C.
Simón Guzmán León, M.en C.	Técnico Académico Titular B. PRIDE C.

Dependiente de la Coordinación de la Investigación Científica, UNAM con sede en el Instituto de Fisiología Celular, UNAM.

Servicios:

- Manejo de bancos y cepas.
- Amplificación de genes y purificación de plásmidos.
- Fabricación de microarreglos de ADN.
- Marcaje de sondas e hibridización de microarreglos de ADN.
- Lectura de microarreglos de ADN.
- Análisis de microarreglos de ADN.

Actividades realizadas durante el año 2019

- Fabricación de microarreglos del genoma completo de levadura.
- Fabricación de microarreglos del genoma completo de *E. coli.*
- Fabricación de microarreglos del genoma completo de H. pylori.
- Fabricación de microarreglos de cáncer humano 2K genes.
- Fabricación de microarreglos de hígado de rata 2K genes.
- Fabricación de microarreglos de ratón 22K genes.
- Fabricación de microarreglos de humano 10K genes.
- Fabricación de microarreglos del genoma humano completo 35K genes.
- Fabricación de microarreglos del genoma completo de *A. thaliana* 30K genes.
- Fabricación de microarreglos del genoma completo de *c. elegans* 20K genes.
- Fabricación de microarreglos de una colección de mini RNAs.
- Diseño y fabricación de un chip para detección de organismos patógenos.

- Diseño y fabricación de un chip para detección de OGMs.
- Diseño y fabricación de un chip para detección de polimorfismos.

En 2019 se recibieron 42 solicitudes de trabajo, de las cuales se entregaron 21 proyectos terminados y pagados. Esto representó más de 180 marcados de sondas, hibridizaciones, lecturas y cuantificaciones de microarreglos para diferentes grupos de investigación de la UNAM y fuera de ella. También se recibieron agradecimientos en 3 trabajos publicados en revistas internacionales y en 1 tesis de doctorado y se dictaron 7 cursos y 4 conferencias.

Comisión de la Unidad de Microarreglos:

Dr. Félix Recillas Targa
Dra. Alicia González
Dr. Luis Tovar y Romo
Dr. Leonardo Peraza
Dr. Gabriel del Río
Secretario Ejecutivo: Dr. Jorge Ramírez

Laboratorio de investigación y desarrollo de Aplicaciones interactivas para la Neuro-Rehabilitación (LANR)

Responsable:

Dra. Herminia Pasantes — **Investigadora Emérita**

M. en C. Ana María Escalante — **Técnico Académico Titular C. PRIDE D**

El Laboratorio de Investigación y Desarrollo de Aplicaciones Interactivas para la Neuro-rehabilitación (LANR) comenzó a funcionar en junio de 2014, en un espacio asignado por la entonces Directora del Instituto de Fisiología Celular (IFC), la Dra. Marcia Hiriart, y con el apoyo decidido de la Dra. Herminia Pasantes, investigadora emérita del IFC, en el edificio de Neurociencias del mismo instituto. La motivación para establecer este laboratorio surge del proyecto de creación de la Licenciatura en Neurociencias en la UNAM, como un espacio para diversificar la preparación de los egresados, en este caso en la línea de la innovación tecnológica para la salud.

El LARN contempla el diseño y el uso de tecnologías en apoyo de las terapias de rehabilitación de pacientes con algún tipo de discapacidad de origen neurológico, congénita o adquirida. En su primera etapa, se ha enfocado a la utilización de sensores de posición y movimiento, conectados a computadoras, tabletas o teléfonos inteligentes, que puedan guiar al paciente en la realización de ejercicios de rehabilitación física, sin requerir el acompañamiento constante de un especialista en rehabilitación. Se trata de desarrollos en lo que se conoce como “juegos serios”, que son interfaces gráficas semejantes a los videojuegos, pero con una finalidad terapéutica y con movimientos y objetivos cuidadosamente trazados.

Hasta el momento se han desarrollado aplicaciones enfocadas a la rehabilitación de pacientes con daño ocasionado por un accidente cerebro vascular (ACV). Se han concluido los prototipos de seis aplicaciones para rehabilitación de extremidad superior y uno para rehabilitación de cabeza y cuello y coordinación ojo-mano. También se han desarrollado prototipos de hardware para un guante de datos, un mouse ergonómico y sensores de posición y movimiento para los pies. Se cuenta ya con el registro de diez de estos programas ante el INDAUTOR y se iniciará el proceso para el registro de al menos otras tres aplicaciones que están en sus etapas finales de elaboración.

Se ha establecido un acuerdo de colaboración entre el IFC con la Unidad de Rehabilitación del Instituto Nacional de Neurología y Neurocirugía Manuel Velasco Suárez de la Ciudad de México, mismo que estamos en el proceso de formalizar mediante un convenio. A través de esta colaboración se llevará a cabo la validación de los beneficios de las aplicaciones desarrolladas en el LANR, así como los ajustes que el personal de salud del INNN considere necesarios, para aplicarlos a los pacientes. Tomando en cuenta la prevalencia del ACV y sus secuelas, y la precariedad de los recursos humanos en salud para atender este problema, creemos que el tipo de aplicaciones elaboradas por el LARN, actualmente y en el futuro, beneficiará a un número grande de pacientes.

Se finalizó el diseño de un guante interactivo y se registraron los diseños de 2 versiones de mouse ergonómico. Se enriqueció la plataforma de juegos a cinco terminados y otros cinco con un avance importante.

Con 4 programas de Servicio Social registrados, contamos con una composición multidisciplinaria: ingenieros en computación, electrónicos, mecatrónicos, diseñadores gráficos, industriales, psicólogos, terapeutas físicos y físicos biomédicos.

Una tesis de licenciatura concluida y 15 estudiantes terminaron el Servicio Social.

Unidad de Bioinformática y Manejo de la Información (UBMI)

Responsable:

César Augusto Poot Hernández, Dr. **Técnico Académico Asociado C. PRIDE B**

Esta Unidad tiene como objetivo el apoyo a la investigación y a la docencia que se realizan en el Instituto. Se llevan a cabo actividades como la administración continua de los servidores de análisis de la Unidad. También se da asesoría continua y seguimiento a estudiantes en temas de manejo y procesamientos de datos de secuenciación masiva en paralelo, análisis y visualización de datos, estadística y métodos de aprendizaje automático. Se colabora con grupos de investigación recomendando métodos alternativos de visualización y análisis de datos fundamentados en el campo de la ciencia de datos. Se asesora al personal académico del IFC, en el manejo de sistemas operativos GNU/Linux y en la conexión remota con los servidores de análisis.

En 2019 se trabajó en la creación de la Unidad de Bioinformática y Manejo de la Información del IFC (UBMI-IFC). En un principio, la Unidad asumió la responsabilidad de la administración y manejo de los dos servidores de análisis del IFC. Posteriormente, se gestionó la migración e instalación de ambos equipos al Site 2 del Edificio Anexo del Instituto y se gestionó la compra de un tercer servidor de análisis. En conjunto, los 3 equipos suman 192 cores de procesamiento y 576 GB de RAM. Durante este periodo, los servidores fueron usados en aproximadamente entre un 40 a 50% de la capacidad sumada total. Adicionalmente se adquirió un sistema de almacenamiento en red (NAS) con 42 TB de almacenamiento redundante para uso interno de la Unidad.

Concomitantemente, se comenzó el desarrollo de un Sistema Estandarizado de Instalación de Software (SEIS) científico basado en la distribución de *software* Anaconda, el cual está dirigido a sistemas operativos GNU/Linux. El objetivo de este sistema es generar un ambiente de trabajo robusto y de fácil instalación que favorezca la implementación de *pipelines* de análisis y la reproducibilidad de resultados.

En tema de servicios, la Unidad prestó servicios de asesoría y/o colaboración con aproximadamente 15 estudiantes de 8 laboratorios de investigación en temas variados como: análisis de datos de secuenciación masiva en paralelo, programación, visualización de datos, aprendizaje de máquina y estadística.

En tema de la docencia, participé como profesor invitado en 2 cursos de la Licenciatura en Neurociencias, en 1 curso del Posgrado de Ciencias Bioquímicas y cómo titular en 2 cursos del posgrado en Ciencias de la Computación del IIMAS, UNAM. Finalmente, se organizó el 1er Simposio de Bioinformática y Biología Computacional del IFC.

Comisión de la Unidad de Bioinofrmática y Manejo de la Información (UBMI):

Dra. Mayra Furlan Magaril
Dr. Julián Valdés
Dr. Marcelino Arciniega
Dr. Gabriel del Rio
Dr. Román Rossi
Secretario Ejecutivo: Dr. Félix Recillas

Unidad de Edición Genética y Criopreservación

Responsable:
Paula Licona Limón, Dra. **Investigador Titular A. PRIDE B. SNI nivel I.**
Ariadna Aparicio Juárez, Dra. **Técnico Académico Asociado "C"**

Las actividades realizadas en la Unidad de Edición Genética y Criopreservación el año 2020 son las siguientes:

Actualmente la Unidad de Edición Genética y Criopreservación brinda **soporte técnico** y **asesorías** en el manejo de diferentes colonias de ratones transgénicos en el Instituto de Fisiología Celular de la Universidad Nacional Autónoma de México.

Se realizaron los primeros ensayos con la técnica de **criopreservación de esperma** en las líneas de ratones CD1, C57/BL6 y 4 Get. Se evaluó la **descongelación de esperma criopreservado** por medio del conteo de viabilidad espermática y los porcentajes de supervivencia. Se realizaron 2 ensayos de **descontaminación de cigotos** murinos en la línea transgénica CHAT-CRE pertenecientes al laboratorio del Dr. Fatuel Tecuapetla. En la **Vasectomización** se utilizaron machos C57/BL6 para la obtención de machos estériles y poder usarlos en la estimulación de las hembras receptoras en la transferencia embrionaria. La **súper ovulación** de hembras murinas C57/BL6 y CD1 para la producción de ovocitos que nos permitieron calibrar el equipo de **microinyección en pronúcleo**. Se hicieron dos ensayos de **rederivación, transferencia embrionaria** e **implantación** de la línea transgénica CHAT-CRE que se mantiene en heterocigosis y se encuentra contaminada por algún agente patógeno. Ensayos de **microinyección** en pronúcleos de cigotos de ratón La Unidad de Edición Genética y Criopreservación junto con le Unidad de Bioterio organizó y participó en 4 ocasiones, con el curso titulado "**Manejo de Animales de Laboratorio en Investigación Biomédica"** para estudiantes, técnicos y académicos del IFC, UNAM con valor curricular de 18 horas.

CONSTRUCCIÓN, REMODELACIÓN, AMPLIACIÓN, ADECUACIÓN DE ESPACIOS Y PROYECTOS ESPECÍFICOS

Programa Institucional de Mantenimiento Verano 2019	**Memoria Fotográfica**
Importe asignado: $149,998.78	 
Trabajos desarrollados: • Sistema de Alarma de Emergencia Edificio Anexo.	

Programa Institucional de Mantenimiento Verano 2019	Memoria Fotográfica
• Pintura vinílica y barniz marino en muros diversas áreas. • Sustitución de lámparas a sistema led de 16 y 36 watts sin balastro en diversos laboratorios	   

Programa Institucional de Mantenimiento Invierno 2019	**Memoria Fotográfica**
Importe asignado: $148,596.05	
Trabajos desarrollados: • Reja metálica de protección en Unidad de Edición Genómica y Criopreservación.	  

Rehabilitación de laboratorios 204 Norte, Dra. Marina Macías y AL-201, Dra. Marcia Hiriart	**Memoria Fotográfica**
Importe aproximado: $400,000.00	
Trabajos desarrollados: • Rehabilitación de mobiliario existente. • Fabricación de mobiliario nuevo. • Trabajos de albañilería, acabados y pintura. • Rehabilitación de Instalaciones • Cambio de lámparas a sistemas led. • Mudanzas. Los trabajos se concluyeron durante el mes de agosto de 2019	**Lab. 224 Norte.- Dra. Marina Macías** 

Lab. AL-201.- Dra. Marcia Hiriart

Cambio de domos en vestíbulo del Edificio Principal y en el sótano Div. Neurociencias	**Memoria Fotográfica**
Importe aproximado: $142,000.00	
Trabajos desarrollados: • Suministro y colocación de domo de policarbonato en vestíbulo del Edificio Principal. • Suministro y colocación de domo de policarbonato en sotáno Div. Neurociencias.	

Cambio de 220 gabinetes de lámparas a sistema led	**Memoria Fotográfica**
Importe aproximado: $80,000.00	
Trabajos desarrollados: • Cambio de 224 gabinetes de lámparas a sistema led de 16 watts sin balastro electrónico en diversos laboratorios y áreas comunes del Instituto	

Resguardo de acervo de la Biblioteca a Almacén de la Administración ubicado en P.B., detrás del Auditorio	**Memoria Fotográfica**
Importe aproximado: $90,000.00	
Trabajos desarrollados: • Adquisición de mas de 300 rejas de plástico para almacenaje del acervo. • Adquisición de tarimas de madera. • Movimiento de libreros metálicos • Tres mudanzas de la Biblioteca al Almacén. • Protección de libreros y rejas con plásticos protectores.	

Impermeabilización de 2,882.00 m2 de azoteas de Edificios Sur, Norte, Biblioteca y Bioterio	**Memoria Fotográfica**
Importe aproximado: $1,123,000.00	
Trabajos desarrollados: • Demolición y retiro de impermeabilizante existente. • Suministro y colocación de Impermeabilizante con sistema prefabricado APP de 4.5 mm. espesor Marca Fester con 15 años de garantía.	

Reacondicionamiento de 2 Aulas y 2 Oficinas en Edificio Anexo	**Memoria Fotográfica**
Importe aproximado: $587,000.00	
Trabajos desarrollados: • Reacondicionamiento de 2 Aulas. • Reacondicionamiento de 2 Oficinas. • 2 Pantallas de 70". • 4 Pizarrones blancos. • 40 butacas y 2 escritorios para profesores.	 

Rejas metálicas de protección junto a artesa y portón de acceso a estacionamiento	**Memoria Fotográfica**
Importe aproximado: $68,000.00	
Trabajos desarrollados: • Reja metálica de protección entre Unidad de Edición Genómica y artesa. • Portón en acceso a estacionamiento	 

ANEXOS

Anexo 1

Alumnos

Alumnos de Doctorado en Ciencias Biomédicas

	Alumno	Tutor
1	Achouna Angele Sorel	Fernández de Miguel Francisco
2	Agoitia Polo Andrés	Bermúdez Rattoni Federico
3	Aguilar Solis Eduardo Daniel	Valdés Rodríguez Víctor Julián
4	Alatriste León Héctor	Tecuapetla Aguilar Fatuel
5	Albert Garay Jesús Silvestre	Salceda Sacanelles Rocío
6	Álvarez Arce Erik Alejandro	López Colomé Ana María
7	Aparicio Juárez Ariadna	Bargas Díaz José
8	Arteaga Tlecuitl Rogelio	Gómora Martínez Juan Carlos
9	Arzate Mejía Rodrigo Gacel	Recillas Targa Félix
10	Avilés Rosas Víctor Hugo	Bargas Díaz José
11	Ayhllon Osorio Carlos Alberto	Hernández Muñoz Rolando Efraín
12	Bahena Alvarez Daniel	Hernández Cruz Arturo
13	Benítez Angeles Miguel	Rosenbaum Emir Tamara Luti
14	Cabrera Ruiz Elizabeth	Lemus Sandoval Luis
15	Cáceres Chávez Verónica Alejandra	Bargas Díaz José
16	Calderon Ortiz Bladimir Melecio	Bargas Díaz José
17	Campero Romero Aura Nirva	Tovar y Romo Luis Bernardo
18	Cárdenas Rivera Alfredo	Tovar y Romo Luis Bernardo
19	Carmona Aldana Francisco Javier	Recillas Targa Félix
20	Carmona Rosas Gabriel	García Sáinz Jesús Adolfo
21	Carranza García Emilio	Navarro González Rosa Estela
22	Cerecedo Castillo Angel Josué	Recillas Targa Félix
23	Chávez Maldonado Juan Pablo	Hiriart Urdanivia Marcia
24	Collazo Navarrete Omar	Drucker Colin René/Guerra Crespo
25	Contreras López Rubén Darío	Tecuapetla Aguilar Fatuel
26	Cortés Fernández de Lara Josué Daniel	Recillas Targa Félix
27	Damián Zamacona Salvador	Mas Oliva Jaime
28	Díaz de León Benbow Gabriel	Romo Trujillo Ranulfo
29	Diaz Hernández Edgar Arturo	Tecuapetla Aguilar Fatuel
30	Díaz Mazariegos Selma	Pérez Montfort Ruy

31	Díaz Osornio Jaime Héctor	Romo Trujillo Ranulfo
32	Duhne Ramírez Mariana	Bargas Díaz José
33	Equihua Benítez Ana Clementina	Drucker Colí René
34	Fuentes Ramírez Emma Oliva	González Halphen Diego
35	García Hernández Brenda Vianey	Morán Andrade Julio
36	García Patiño María Guadalupe	Licona Limón Paula
37	García Vilchis Ana Brisa	Galarraga Palacio Elvira
38	Garza Domínguez Ramiro	Torres Quiroz José Francisco
39	Gil Lievana Elvi	Bermúdez Rattoni Federico
40	Gómez Paz Alejandra Liliana	Drucker Colín René
41	González García Sergio Diego	Pérez de la Mora Miguel
42	Gorostieta Salas Gently Elisa	Castro Obregon Susana
43	Guerrero Celis Nuria	Chagoya Hazas Victoria
44	Gutiérrez Terrazas Sammy Israel	Hansberg y Torres Wilhelm Ludwig
45	Guzmán Vázquez Khalil	Drucker Colin René
46	Heras Romero Yessica Rosalinda	Tovar y Romo Luis Bernardo
47	Hernández Espinosa Diego Rolando	Morán Andrade Julio
48	Hernández Jaramillo Alejandra Aidaly	Sotres Bayón Francisco Xavier
49	Hernández Jiménez Ana María	Chagoya Hazas Victoria
50	Hernández Mondragón Juan Carlos	Pérez de la Mora Miguel
51	Illescas Huerta Elizabeth Sarahi	Sotres Bayón Francisco Xavier
52	Lara González Esther	Bargas Díaz José
53	Lara Rodarte Ernesto José Rolando	Velasco Velázquez Jaime Iván
54	Lazo Gómez Rafael Esaid	Tapia Ibargüengoytia Ricardo
55	Mata Herrera Miguel Ángel	Lemus Sandoval Luis
56	Maya Espinosa María Guadalupe	Drucker Colin René
57	Melchor Hernández Jonathan	Lemus Sandoval Luis
58	Méndez Rodríguez Beatríz Sarahí	Galarraga Palacio Elvira
59	Morales García Norma Lilia	Uribe Carvajal Salvador
60	Morán Martínez Isaac	Lemus Sandoval Luis
61	Noguez Garrido Paula Leticia	Fernández de Miguel Francisco
62	Núñez Martínez Hober Nelson	Recillas Targa Félix
63	Padilla Orozco Montserrat	Bargas Díaz José
64	Palacios Lagunas Daniel Alejandro	Pérez de la Mora Miguel
65	Parada Parra Oscar Javier	Hernández Cruz Arturo
66	Parra Sánchez Sergio	Romo Trujillo Ranulfo
67	Peláez Coyotl Erika Alejandra	Del Río Guerra Gabriel
68	Peña Del Castillo Johanna Guadalupe	Hernández Cruz Arturo
69	Peralta Alvarez Carlos Alberto	Recillas Targa Félix

70	Ramírez López María Fernanda	Drucker Colin René
71	Ramírez Vidal Lizbeth Rocío	López Casillas Fernando
72	Reyes Chapero Rosa María	Galarraga Palacio Elvira
73	Rosendo Pineda Margarita Jacaranda	Vaca Domínguez Luis Alfonso
74	Ruvalcava Gracia Medrano Diana	González Halphen Diego
75	Sánchez Fuentes Asaí	Tecuapetla Aguilar Fatuel
76	Sánchez Sugia María Celeste	Fernández de Miguel Francisco
77	Sánchez Zavaleta Minerva	Salceda Sacanelles Rocío
78	Serrano Reyes Miguel	Bargas Díaz José
79	Solís González Karina Helivier	García Sáinz Jesús Adolfo
80	Torres Esquivel María del Carmen	Massieu Trigo María de Lourdes
81	Valencia Sánchez Salvador	Drucker Colín René
82	Vázquez Vázquez Héctor Aarón	Galarraga Palacio Elvira
83	Velázquez Hernández Leon Gerónimo	Sotres Bayón Francisco Xavier
84	Vergara de la Fuente José	Romo Trujillo Ranulfo
85	Zepeda Cervantes Jesús	Vaca Domínguez Luis Alfonso
86	Zizumbo Colunga Gerónimo	Rossi Pool Román

Alumnos de Doctorado en Ciencias Bioquímicas

	Alumno	Tutor
1	Acevo Rodríguez Pilar Sarah	Castro Obregón Susana
2	Angel Lerma Lidia Esmeralda	Georgellis Dimitris
3	Avendaño Monsalve María Clara	Funes Argüello María Soledad
4	Bastian Eugenio Carlos Ernesto	Vaca Domínguez Luis Alfonso
5	Bernal Vicente Berenice Nohemi	Tovar y Romo Luis Bernardo
6	Campos Martínez Gisselle Angélica	Navarro González Rosa Estela
7	Castillo Casaña Yaisa	Coria Ortega Roberto
8	Cid Castro Carolina	Morán Andrade Julio
9	Contreras Castillo Eugenio	Licona Limón Paula
10	De la Fuente León Rosa Luz	López Casillas Fernando
11	De las Peñas Rincón Ana Paulina	Sotres Bayón Francisco Xavier
12	Díaz Guerrero Miguel Ángel	González Pedrajo Bertha
13	Espinosa Molina Gabriela	Salceda Sacanelles Rocío
14	Espinosa Simon Emilio	Uribe Carvajal Salvador
15	Flores Mireles Daniel	Pérez Martínez Xochitl
16	Flores Ponce Xochitl Natalia	Velasco Velázquez Jaime Iván
17	Franco Juárez Berenice	Castro Obregón Susana
18	Fuentes Jiménez Daniel Alberto	Navarro González Rosa Estela
19	Gálvez Márquez Donovan Kevin	Bermudez Rattoni Federico
20	García Chávez Diana María	Coria Ortega Roberto
21	González Rangel Alan Anuart	Navarro González Rosa Estela
22	Guzmán Flores José Enrique	Georgellis Dimitris
23	Guzmán Silva Alejandro	García Sáinz Jesús Adolfo
24	Hernández Araiza Ileana Raquel	Rosenbaum Emir Tamara Luti
25	Hernández Elvira Mariana	Coria Ortega Roberto
26	Hernández Espinosa David Alejandro	García Sáinz Jesús Adolfo
27	Jiménez Suárez Alejandra	González Halphen Diego
28	López Niño Janintzitzic	Bargas Díaz José
29	Lozano Rosas María Guadalupe	Chagoya Hazas Victoria
30	Luna Reyes Ismael	Mas Oliva Jaime
31	Madrigal Carrillo Ezequiel Alejandro	Torres Larios Alfredo
32	Marcos Vilchis Arely Ivonne	González Pedrajo Bertha
33	Márquez Gutiérrez Dariel	González Manjarrez María Alicia
34	Martínez Morales Juan Carlos	García Sáinz Jesús Adolfo
35	Martínez Pastor David	Macias Silva Marina

102	Sánchez Hernández Raúl	Rosenbaum Emir Tamara Luti
103	Sánchez Salazar Zyanya Saraí	Hiriart Urdanivia Marcia
104	Sandoval Hernández José Antonio	Macías Silva Marina
105	Soltero Echauri Cintia	Macías Silva Marina
106	Soto Beltran Ana María	Coria Ortega Roberto
107	Steinemann Hernández Lidia	Georgellis Dimitris
108	Stephenson Gussinye Aura	Furlan Magaril Mayra
109	Toca de Muga Paulina	Del Río Guerra Gabriel
110	Torres Morales Erika Monserrat	Hernández Cruz Arturo
111	Torres Reyes María del Pilar	González Pedrajo Bertha
112	Trejo Hernández Diana Laura	Recillas Targa Félix
113	Urrieta Chávez Beetsi Eugenia	Velasco Velázquez Jaime Iván

114	Velázquez Delgado Cintia	Bermúdez Rattoni Federico
115	Vergara Gerónimo Cristian Alberto	Pérez Martínez Xochitl
116	Villafuerte Peralta Rafael	Sotres Bayón Francisco Xavier
117	Vivar Cortés Israel César	Bargas Díaz José
118	Wilson Verdugo Marti David	Valdés Rodríguez Víctor Julián
119	Zavala Sánchez José Hugo	Hiriart Urdanivia Marcia
120	Zepeda Gutiérrez Paula	Macías Silva Marina

Alumnos de Maestría en Ciencias Biológicas

	Alumno	Tutor
1	Cortés Escamilla Cicilia Estrella	Gómora Martínez Juan Carlos
2	Garcia Ramos Mariela	Dreyfus Cortés Georges
3	Jiménez Marquez Emiliano	Ramiro Cortés Yazmín
4	Juárez Contreras Rebeca	Morales Lazaro Sara Luz
5	Landa Navarro Lucía	Bermúdez Rattoni Federico
6	Linares Garcia Carlos Iván	Tecuapetla Aguilar Fatuel
7	Ortiz Cruz Carlos Alberto	Ramiro Cortés Yazmín
8	Perera Murcia Gerardo	Ramiro Cortés Yazmín
9	Verma Rodríguez Anil Kumar	Tecuapetla Aguilar Fatuel

Alumnos de otra Maestria

	Alumno	Tutor
1	Albor Ramírez Efraín	Vaca Domínguez Luis Alfonso
2	Mejía López Adriana	Aguilar Roblero Raúl
3	Sánchez Evangelista Grecia	Morán Andrade Julio

Alumnos Tesistas de Licenciatura

	Alumno	Tutor
1	Abarca Magaña Julio Cesar	Massieu Trigo María Lourdes
2	Abelar Cámara Abelardo	Picones Medina Arturo
3	Acevedo Huerta Cecilia Gabriela	Bermúdez Rattoni Federico
4	Acosta Galeana Maria Isabel	Tapia Ibargüengoytia Ricardo Jorge
5	Aguilar Cámara Abelardo	Picones Medina Arturo
6	Aguilar Quiroz Diana Mitzi	Hernández Cruz Arturo
7	Amezola Chávez Francisco Manuel	Torres Quiroz José Francisco
8	Arenas Navarro Andrés	Castro Obregón Susana
9	Beltrán Calderón Yesica	Torres Larios Alfredo
10	Bernal Servín Aida	Hernández Cruz Arturo
11	Bustamante Carrera Manuel Alejandro	Escalante Gonzalbo Ana
12	Bustos Vázquez Cinthya Dafne	Bermúdez Rattoni Federico
13	Caballero Escamilla Brenda Aurora	González Manjarrez Alicia
14	Campos Ortega Rendón Sergio	Arciniega Castro Marcelino
15	Cruz Mendoza Leticia	Dreyfus Cortés Georges
16	Cruz Montesinos Luis Ángel	Pérez de la Mora Miguel
17	De los Santos Cocotle Gustavo	Garcia Sainz Jesús Adolfo
18	Delgado Gómez Giselle Alexa	Guerra Crespo Magdalena
19	Elias López Diana Lizbeth	Gómora Martínez Juan Carlos
20	Enciso Pablo Oscar	Morales Lazaro Sara Luz
21	Escudero Reyes Juan Raúl	González Manjarrez Alicia
22	Estrada Rosales Ana Lilia	Escalante Gonzalbo Ana
23	Felipe González Víctor Martín	Aguilar Roblero Raúl
24	García Cordero Itzel Abil	Pérez Martínez Xochitl
25	García Fidencio Víctor Alejandro	Arciniega Castro Marcelino
26	García Mata Martín	Bargas Díaz José
27	Gasca Aguilera Luis Enrique	Navarro González Rosa Estela
28	Godinez López Victoria	Torres Larios Alfredo
29	Gómez Martínez Cecilia Gabriela	Ramiro Cortés Yazmín
30	González Ríos Axel Rubén	López Huerta Violeta Gissell
31	González Ruiz Karla Daniela	Garcia Sainz Jesús Adolfo
32	Gutierrez Castañeda Oscar Eduardo	Arciniega Castro Marcelino
33	Gutiérrez López Ernesto Saúll	Bermúdez Rattoni Federico
34	Hernández Matias Arturo	Osorio Gómez Daniel
35	Herrera Xithe Gabriela	Bermúdez Rattoni Federico

36	Jaimes Cabrera José	Osorio Gómez Daniel
37	Linares Caballero Brenda	Osorio Gómez Daniel
38	Martínez Cruz Jadir Isaí	Tapia Ibargüengoytia Ricardo Jorge
39	Martínez Velasco Rosario Paulina	Torres Quiroz José Francisco
40	Meza González Viridiana Belén	Escalante Alcalde Diana María
41	Meza Razo Rodrigo	López Casillas Fernando
42	Morales Moreno Ishbelt Denisse	Guerra Crespo Magdalena
43	Moreno de la Rosa Dinorah Ileana	Torres Quiroz José Francisco
44	Navarro Espindola Raful	Peraza Reyes Carlos Leonardo
45	Nieto Zaragoza Elias	Torres Quiroz José Francisco
46	Padilla Garfias Francisco Javier	Peña Díaz Antonio
47	Pérez Rivera Iván Dessaeu	Escalante Gonzalbo Ana
48	Pérez Velázquez Diego	Licona Limón Paula
49	Polanco Maldonado Ángel Lizandro	Velasco Velázquez Jaime Iván
50	Portillo Pérez Luisa María	Gómora Martínez Juan Carlos
51	Pulido Arteaga Rafael	Romo Trujillo Ranulfo
52	Ramirez Rivera Viridiana Guadalupe	Pérez de la Mora Miguel
53	Reyes Becerril Luis Uriel	Hansberg Torres Wilhelm Ludwig
54	Ríos Vázquez Mariana	González Pedrajo Bertha
55	Rodríguez Pié Adrian Antonio	Arciniega Castro Marcelino
56	Romero Enriquez Kébek	Dreyfus Cortés Georges
57	Ruiz Juárez Mariana	Sotres Bayón Francisco Xavier
58	Salazar Ortiz Claudia	Pérez Montfort Ruy
59	Salazar Rios Iván Moisés	Escalante Gonzalbo Ana
60	Salcido Gómez Ashley Michel	Massieu Trigo María Lourdes
61	Sánchez Castillo Gloria Ixchel	Escalante Gonzalbo Ana
62	Sánchez Ramos Arizbeth	Ramiro Cortés Yazmín
63	Soriano Rosales Eric Dilan	Recillas Targa Félix
64	Vázquez Ayala Uriel de Jesus	Gómora Martínez Juan Carlos
65	Zambrano Trejo Daniela	González Manjarrez Alicia

Alumnos de Estancia de Investigación

	Alumno	Tutor
1	Álvarez Carreño Claudia	Arciniega Castro Marcelino
2	Bernal Reza Mauricio	Fernández de Miguel Francisco
3	Campos Oliver Brisa Aranzanzú	González Manjarrez Alicia
4	Cancino Bello Amairani	Chagoya Hazas Victoria Eugenia
5	Cárdenas Rodríguez Mauricio	Funes Argüello María Soledad
6	Chaverri Herrera Miriam	Rivera Cerecedo Claudia
7	Escutia Macedo Ximena Ameyalli	Escalante Gonzalbo Ana
8	Eslava Torres Viridiana Guadalupe	Escalante Gonzalbo Ana
9	Florentino Moreno Alejandra	Fernández de Miguel Francisco
10	Franco Castro Paulina	Escalante Gonzalbo Ana
11	Gutiérrez García María Fernanda	Escalante Gonzalbo Ana
12	Juárez Segura Lizbeth	Rivera Cerecedo Claudia
13	Llanos Mis Jessica Klauzeen	Escalante Gonzalbo Ana
14	Loeza Loeza Jacqueline	Recillas Targa Félix
15	Martínez Cervantes Juan Carlos	López Huerta Violeta Gissell
16	Olmos Ojeda Paola Gabriela	Escalante Gonzalbo Ana
17	Pérez Estrada José Raúl	Castro Obregón Susana
18	Pérez Herrera Carlos Alexis	Escalante Gonzalbo Ana
19	Ramírez Cordero Belén Ernestina	Gómora Martínez Juan Carlos
20	Ramírez Guzmán Sergio Sebastián	Escalante Gonzalbo Ana
21	Robles Hernández Eva María	Escalante Gonzalvo Ana
22	Rodríguez González Mario Raúl	Morán Andrade Julio Eduardo Roque
23	Rodríguez Muñoz Diana Laura	López Huerta Violeta Gissell
24	Rodriguez Plaza Jonathan Gabriel	Del Río Guerra Gabriel
25	Rojas Pacheco Erick Antonio	López Huerta Violeta Gissell
26	Román Carraro Fiordaliso Cardina	Morán Andrade Julio Eduardo Roque
27	Salcedo Tello Pamela	Bermúdez Rattoni Federico
28	Schroder Sara	Peraza Reyes Carlos Leonardo
29	Tapia Vieyra Juana Virginia	Mas Oliva Jaime
30	Torres Zavaleta José Manuel	Hernández Muñoz Rolando Efraín
31	Vazquez Abundes Sandra Elizabeth	Escalante Gonzalbo Ana

Alumnos de Taller

	Alumno	Tutor
1	Avila Tapia Sara Iram	Bermúdez Rattoni Federico
2	Balbuena García Brenda Valeria	Bermúdez Rattoni Federico
3	Canizales Ontiveros Alejandro	Salceda Sacanelles Rocío
4	Carrillo Lorenzo José Alberto	Bermúdez Rattoni Federico
5	González Urzúa Erika Vianey	Bermúdez Rattoni Federico
6	Hernandez Mojica Jorge Efren	Peraza Reyes Carlos Leonardo
7	Jesús Valencia Sanchez Katherine Alide	Georgellis Dimitris
8	Jiménez Negrete Celina	Georgellis Dimitris/Adrian Alvarez Fernando
9	Manzanita Quintero Katya	López Colomé Ana María
10	Mendoza Rodríguez Edgar	López Colomé Ana María
11	Montiel Alcazar Andrea	López Colomé Ana María
12	Rogerio Rios Jaime Emiliano	Tovar y Romo Luis Bernardo
13	Saenz Rodríguez Fernando	Salceda Sacanelles Rocío
14	Tenorio Hernández Luis	Ramiro Cortés Yazmín
15	Torres Torralba Erick Nicolas	Salceda Sacanelles Rocío

Alumnos de Rotación de LIBB

	Alumno	Tutor
1	Blanco Salazar María José	Recillas Targa Félix
2	Bravo Arevalo José Ernesto	Funes Arguello María Soledad
3	Campos Chávez Eduardo	Torres Larios Alfredo
4	Cristino Miranda Arianne Melisa	Castro Obregón Susana
5	Flores Espinosa Emannuel	Garcia Sainz Jesús Adolfo
6	Marroquin Rodríguez Montserrat	Navarro González Rosa Estela
7	Moreno Yllescas Christopher Levitt Alejandro	González Halphen Diego
8	Nava García Marintia Mayola	Furlan Magaril Mayra
9	Peredes Chiquini Yamilé	González Manjarrez Alicia
10	Soriano Rodríguez Carla Itzel	Velasco Velázquez Jaime Iván

Alumnos de Licenciatura en Neurociencias

	Alumno
1	Abrego Islas Iván de Jesús
2	Acevedo Garduño Nuri
3	Albanes Sánchez Cesar Ulises
4	Andrade Ortega Bernardo
5	Avilez Poblador Karla Gabriela
6	Barreras Maldonado José Carlos
7	Batiz Slazak Pola Luz
8	Bautista Galicia Ramssés Jair
9	Becerril Huerta Bibiana Carolina
10	Bravo Lanz Carolina
11	Buendía Sánchez Luis Antonio
12	Cabrera Castro Maricela
13	Campos Pérez Andrea Fernanda
14	Cano Gómez Montserrat
15	Casas Rosas Karla Patricia
16	Castañeda Ferrer Lolbe
17	Castilla Jiménez Jaiver Francisco
18	Chávez Blancas Isaac
19	Cruz Sánchez Oscar Apolinar
20	Cuellar Torres José Manuel
21	De La Cruz Magaña Mauricio
22	Del Río Castro Camila
23	Diaz Zarate Xarenny Yazmin
24	Espinosa Rodríguez Andrea
25	Figueroa Cruz Julio Cesar
26	Franceschi Jiménez Luis Arturo
27	García Kroepfly Aidee Lashmi
28	García López Paulina
29	Garduño Almaraz Angel
30	Gómez García Ozmar Saul
31	Gómez Mendoza Juan Carlos
32	Gómez Villatoro Johana Paulina
33	González Martínez Salvador Eduardo
34	Hernández Real Fernando

35 Herrera Zahar Daniela Michelle
36 Jiménez Gallardo Alejandro
37 Jiménez Pérez Angela Renata
38 Linares García Ana Paola
39 Lombardi Martínez Daniel
40 Lora Marín Obed Ricardo
41 Manriquez Cejudo Alejandra
42 Martínez Guadarrama Andrea
43 Martínez Mata Karina
44 Martínez Pérez Michelle
45 Mejía Ortiz Regina Andrea
46 Mendoza Madrigal Rodrigo
47 Montes Montiel José María
48 Montiel González Valeria
49 Navarrete Hernandez Vania Lizeth
50 Navarro Magallón Javier
51 Novela Maciel Ana Teresa
52 Núñez García Diana
53 Ocampo Romero Ana Gabriela
54 Quintero Hernández Dariana Guadalupe
55 Rico Becerra Allan Irasek
56 Rocha Estrada Karla Patricia
57 Rodríguez López Blanca Estela
58 Rodríguez Vera Andrea
59 Rodríguez Vertiz Fatima Itzel
60 Rubio Galicia Angel
61 Ruiz Alanis Emilio
62 Ruiz Antonio Diana Lizeth
63 Ruiz Ortega Montserrat
64 Salazar Castro Marelly
65 Sánchez Calderon Eder Raziel
66 Sánchez Cortes Flor Erendira
67 Sánchez Velázquez Alan
68 Sandoval González Cesar
69 Santana Roman Estefanía
70 Santiago Bustos Ángel Eduardo
71 Silvas Baltazar Diana Monserrat
72 Torres Leyva Itzel Beatriz
73 Treviño Juárez Denisse Monserrat

74 Tripp Avalos Joseph Marino
75 Trujillo Carreno Santiago
76 Valencia Morales Arisbeth Citlali
77 Vázquez Lechuga Arenski Sugel
78 Vázquez Zuloeta Samantha
79 Velasco Orozco Miguel
80 Vilchis Macias Erik Hazel
81 Zavaleta Zamora Carlos Rafael

Alumnos Graduados

Graduados de Doctorado en Ciencias Biomédicas

	Alumno	Tutor
1	Aparicio Juárez Ariadna	Bargas Díaz José
2	Arteaga Tlecuitl Rogelio	Gómora Martínez Juan Carlos
3	Cáceres Chávez Verónica Alejandra	Bargas Díaz José
4	Cárdenas Rivera Alfredo	Tovar y Romo Luis Bernardo
5	Carmona Aldana Francisco Javier	Recillas Targa Félix
6	Carmona Rosas Gabriel	García Sáinz Jesús Adolfo
7	Carranza García Emilio	Navarro González Rosa Estela
8	Díaz Hernández Edgar Arturo	Tecuapetla Aguilar Fatuel
9	Hernández Espinosa Diego Rolando	Morán Andrade Julio
10	Maya Espinosa María Guadalupe	Drucker Colin René
11	Ruvalcava Gracia Medrano Diana	González Halphen Diego
12	Zepeda Cervantes Jesús	Vaca Domínguez Luis Alfonso

Graduados de Doctorado en Ciencias Bioquímicas

	Alumno	Tutor
1	Guzmán Flores José Enrique	Georgellis Dimitris
2	Hernández Araiza Ileana Raquel	Rosenbaum Emir Tamara Luti
3	Hernández Elvira Mariana	Coria Ortega Roberto
4	Juárez Arellano Vladimir	Del Río Guerra Gabriel
5	Mendoza Martínez Ariann Elizabeth	Aguirre Linares Jesús
6	Rendón Ochoa Ernesto Alberto	Bargas Díaz José
7	Rodríguez Bolaños Mónica	Pérez Montfort Ruy
8	Rodríguez González Miriam Beatriz	Coria Ortega Roberto
9	Terán Melo Juan Luis	Georgellis Dimitris
10	Vazquez Ibarra Araceli Berenice	Coria Ortega Roberto
11	Zaragoza Campillo Marco Antonio	Morán Andrade Julio

Graduados de Doctorado en Ciencias Biológicas

	Alumno	Tutor
1	Alejandre García Maria Mildred Tzitzitlini	Hernández Cruz Arturo
2	Méndez Maldonado Karla M. del Carmen	Velasco Velázquez Jaime Iván

Graduados de Maestría en Ciencias Bioquímicas

	Alumno	Tutor
1	Bahena Cerón Roberto Alexander	Torres Larios Alfredo
2	Campos Martínez Gisselle Angélica	Navarro González Rosa Estela
3	Castañeda Arroyo Aurora Angélica	Hernández Muñoz Rolando
4	Contreras Castillo Eugenio	Licona Limón Paula
5	Cruz Ramos Juan Eduardo	Macías Silva Marina
6	Del Ángel Muñoz Carlos Miguel	Castro Obregón Susana
7	Dimas Torres Jorge Uriel	Torres Larios Alfredo
8	Gálvez Márquez Donovan Kevin *	Bermúdez Rattoni Federico
9	Jara Servín Angélica Mariana	González Manjarrez Alicia
10	López Fuentes Antonio de Jesús	Peraza Reyes Leonardo
11	López Romero Ana Elena	Rosenbaum Emir Tamara Luti
12	Luna Reyes Ismael	Mas Oliva Jaime
13	Montes Ortega Luis Ángel	Massieu Trigo María de Lourdes
14	Morán Torres Rafael Ubaldo	Del Río Guerra Gabriel
15	Nava Lara Rodrigo Andrés	Del Río Guerra Gabriel
16	Olivares Reséndiz Abiram Eliab	Coria Ortega Roberto
17	Ortega Gurrola Alonso	Velasco Velázquez Jaime Iván
18	Ortiz Renteria Miguel	Morales Lazaro Sara Luz
19	Pacheco Martínez María Elena	Hansberg Torres Wilhelm Ludwig
20	Penagos Puig Andrés *	Furlán Magaril Mayra
21	Ramírez Reyes Josué Miguel Julián	Funes Argüello Soledad
22	Rodríguez Sibrian Luis Antonnio	Tecuapetla Aguilar Fatuel
23	Rojo Rodríguez Juliana Berenice	Coria Ortega Roberto
24	Romo Casanueva Hernán *	Funes Argüello Soledad
25	Salgado Ménez Mildred	Bermúdez Rattoni Federico
26	Stephenson Gussinye Aura	Furlán Magaril Mayra
27	Torres Morales Erika Montserrat	Hernández Cruz Arturo
28	Vergara Gerónimo Cristian Alberto *	Pérez Martínez Xochitl
29	Wilson Verdugo Marti David *	Valdés Rodríguez Víctor

***** Alumnos que se graduaron por defensa de proyecto.

Graduados de Maestría en Ciencias Biológicas

	Alumno	Tutor
1	Alejandre García María Mildred Tzitzitlini	Hernández Cruz Arturo
2	García Ramos Mariela	Dreyfus Cortés Georges
3	Juárez Contreras Rebeca	Morales Lazaro Sara Luz
4	Landa Navarro Lucía	Bermúdez Rattoni Federico
5	Linares García Carlos Iván	Tecuapetla Aguilar Fatuel
6	Perera Murcia Gerardo	Ramiro Cortés Yazmín
7	Verma Rodríguez Anil Kumar	Tecuapetla Aguilar Fatuel

Graduados de Licenciatura

	Alumno	Tutor
1	Arenas Navarro Andrés	Celis Sandoval Heliodoro
2	Bravo Arévalo José Ernesto	Funes Argüello María Soledad
3	Calixto Tlacomulco Sandra Daniela	Mas Oliva Jaime
4	Campos-Ortega Rendón Sergio	Arciniega Castro Marcelino
5	Gutiérrez Jaber Inés Fernanda	Bermúdez Rattoni Federico
6	Jiménez Marquez Emiliano	Ramiro Cortés Yazmín
7	Llanos Moreno Argelia Itzel	Tecuapetla Aguilar Fatuel
8	Morales Ramírez Elena	Salceda Sacanelles Rocío
9	Padilla Garfias Francisco Javier	Peña Díaz Antonio
10	Pérez Vázquez Diego	Licona Limón Paula
11	Ricardez García Carolina	Celis Sandoval Heliodoro
12	Ríos Vázquez Mariana	González Pedrajo Bertha
13	Rodríguez Pié Adrian Antonio	Arciniega Castro Marcelino
14	Serrano Solis David Michel	Fernández de Miguel Francisco Rafael

Anexo 2

Docencia

Cursos de Licenciatura

Miembros del IFC como responsables

1. **Bases moleculares del dolor. Taller**
   Responsable: Rosenbaum Emir Tamara.
   Facultad de Ciencias, UNAM.

   Participantes:
   Morales Lázaro Sara Luz
   Llorente Gil Itzel Alejandra

2. **Biofísica**
   Responsable: Hernández Cruz Arturo.
   Lic. Neurociencias.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Tecuapetla Aguilar Fatuel
   Picones Medina Arturo

3. **Biología celular**
   Responsable: Castro Obregón Susana.
   Lic. Neurociencias.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Gómora Martínez Juan Carlos
   Valdés Rodríguez Víctor Julián
   Peraza Reyes Leonardo

4. **Biología molecular de la célula III**
   Responsable: Salceda Sacanelles Rocío.
   Facultad de Ciencias, UNAM.

5. **Bioquímica**
   Responsable: García Sáinz Jesús Adolfo.
   Lic. IBB.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Peña Díaz Antonio
   López Casillas Fernando

6. **Comunicación neuronal**
   Responsable: Tecuapetla Aguilar Fatuel.
   Lic. Neurociencias.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Tovar y Romo Luis Bernardo
   Massieu Trigo Lourdes
   Morales Lázaro Sara Luz
   Velasco Torres Myrian
   Ramiro Cortés Yazmín
   Fernández De Miguel Francisco

7. **Curso de Bioquímica y biología molecular**
   Responsable: Pérez de la Mora Miguel.
   Facultad de Medicina, UNAM.

8. **Epigenética**
   Responsable: Recillas Targa Félix.
   Centro de Ciencias Genómicas, UNAM.

9. **Fisiología humana**
   Responsable: Hiriart Urdanivia Marcia.
   Facultad de Medicina, UNAM.

10. **Fisiología**
    Responsable: Aguilar Roblero Raúl.
    Lic. IBB.
    Instituto de Fisiología Celular, UNAM.

11. **Histología y microscopía**
Responsable: Escalante Alcalde Diana.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Ramiro Cortés Yazmín
Martínez Silva Ana Valeria
Paredes Díaz Rodolfo
Rincón Heredia Ruth
Rosas Arellano Abraham
Rodríguez Montaño Sandra Daniela
Montiel Montes Teresa

12. **Introducción a las neurociencias**
Responsable: Bargas Díaz José.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Sotres Bayón Francisco
Velasco Velázquez Iván
Tecuapetla Aguilar Fatuel
Zainos Rosales Antonio Paulino

13. **Neurobiología**
Responsable: Morán Andrade Julio.
Facultad de Ciencias, UNAM.

Participantes:
Tapia Ibargüengoytia Ricardo
Tecuapetla Aguilar Fatuel
Ramiro Cortés Yazmín
Velasco Velázquez Iván

14. **Bioquímica y biología molecular**
Responsable: Uribe Carvajal Salvador.
Facultad de Medicina, UNAM.

15. **Taller Diferenciación celular en hongos**
Responsable: Aguirre Linares Jesús.
Facultad de Ciencias, UNAM.

Participantes:
Coria Ortega Roberto
Wilhelm Hansberg
Kawasaki Watanabe Laura
Sánchez González Alma Olivia

16. **Taller de Fisiología de canales iónicos**
Responsable: Hernández Cruz Arturo.
Facultad de Ciencias, UNAM.

Participantes:
Picones Medina Arturo

17. **Taller, Transducción de señales y quimiotaxis microbiana**
Responsable: Dreyfus Georges.
Responsable: Georgellis Dimitris.
Facultad de Ciencias, UNAM.

Participantes:
Álvarez Adrián Fernando

18. **Taller: Mecanismos de muerte neuronal**
Responsable: Morán Andrade Julio.
Facultad de Ciencias, UNAM.

19. **Taller: Neurobiología sensorial**
Responsable: Salceda Sacanelles Rocío.
Facultad de Ciencias, UNAM.

20. **Epistemología**
Responsable: Bargas Díaz José.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

21. **Modelos computacionales**
Responsable: Rossi Pool Román.
Lic. Neurociencias.
Facultad de Medicina, UNAM.

Participantes:
Poot Hernández Augusto César

22. **Neuropatología**
Responsable: Massieu Trigo Lourdes.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Velasco Torres Myrian
Velasco Velázquez Iván

23. **Neuroplasticidad**
Responsable: Sotres Bayón Francisco.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Ramiro Cortés Yazmín
Ramírez Lugo Leticia
Rodríguez Durán Luis Francisco

24. **Psicofisiología**
Responsable: Osorio Gómez Daniel.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Sotres Bayón Francisco

25. **Técnicas y herramientas I**
Responsable: López Huerta Violeta Gisselle.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
Tovar y Romo Luis Bernardo
Valdés Rodríguez Víctor Julián
Osorio Gómez Daniel
Escalante Alcalde Diana
Jiménez Pérez Nicolás
Palomero Rivero Marcela
Montiel Montes Teresa

26. **Bioética**
Responsable: Tapia Ibargüengoytia Ricardo.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

27. **Técnicas y herramientas II**
Responsable: Ongay Larios Laura.
Lic. Neurociencias.
Instituto de Fisiología Celular, UNAM.

Participantes:
López Casillas Fernando
Coria Ortega Roberto
Tovar y Romo Luis Bernardo
Códiz Huerta Guadalupe
Velasco Loyden Gabriela
Poot Hernández Augusto César

28. **Introducción a la Biofísica**
Responsable: Álvarez López Jesús Manuel.
Facultad de Ingeniería, UNAM.

29. **Laboratorio de fundamentos de instrumentación Biomédica**
Responsable: Álvarez López Jesús Manuel.
Responsable: Díaz Osornio Jaime Héctor.
Facultad de Ingeniería, UNAM.

30. **Laboratorio de medición e instrumentación**
Responsable: Barbosa Castillo Juan Manuel.
Facultad de Ingeniería, UNAM.

31. **Biología de Hongos**
Responsable: Cano Domínguez Nallely.
Facultad de Ciencias, UNAM.

32. **Algebra lineal**
Responsable: Díaz Osornio Jaime Héctor.
Facultad de Ingeniería, UNAM.

33. **Proyecto de ingeniería**
Responsable: Escalante Gonzalbo Ana María
División de Ingeniería mecánica e industrial, licenciatura en mecatrónica, UNAM.

34. **Biología III**
Responsable: Escobedo Ávila Itzel.
Colegio de Ciencias y Humanidades, Plantel Sur, UNAM.

35. **Biología IV**
Responsable: Escobedo Ávila Itzel.
Colegio de Ciencias y Humanidades, Plantel Sur, UNAM.

36. **Biología molecular de la célula I**
Responsable. Guzmán León Simón.
Facultad de Ciencias, UNAM.

37. **Curso de biotecnología I**
Responsable: Kawasaki Watanabe Laura.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

38. **Biología molecular de la célula I**
Responsable: Lara María Teresa.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

39. **Biología y técnicas de animales de laboratorio**
Responsable: Malagón Rivero Héctor Alfonso.
Facultad de Ciencias, UNAM.

40. **Biología celular e histología médica**
Responsable: Millán Aldaco Diana Alicia.
Carrera de Médico Cirujano.
Facultad de Medicina, UNAM.

41. **Práctica de Medicina zootecnia en animales de laboratorio**
Responsable: Rivera Cerecedo Claudia Verónica.
Facultad de Medicina Veterinaria y Zootecnia, UNAM.

42. **Informática biomédica I**
Responsable: Moncada Hernández Sandra
Departamento de Informática Biomédica
Facultad de Medicina, UNAM.

43. **Informática biomédica II**
Responsable: Moncada Hernández Sandra
Departamento de Informática Biomédica
Facultad de Medicina, UNAM.

44. **Biofísica**
Responsable: Picones Medina Arturo.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

45. **Biología Molecular de la Célula II**
Responsable: Ramírez Jarquín Josué Orlando.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

46. **Biología de animales II**
Responsable: Ramírez Jarquín Josué Orlando.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

47. **Fisiología animal**
Responsable: Ramírez Jarquín Josué Orlando.
Licenciatura en Biología.
Facultad de Ciencias, UNAM.

48. **Curso-taller de Neurobiología del aprendizaje y la memoria**
Responsable: Rodríguez Durán Luis Francisco.
Departamento de Biología celular.
Facultad de Ciencias, UNAM.

49. **Prácticas de Psicobiología**
Responsable: Zainos Rosales Antonio Paulino.
Licenciatura en Psicología.
Facultad de Psicología, UNAM.

50. **Neurocognición**
Responsable: Zainos Rosales Antonio Paulino.
Licenciatura en Psicología.
Facultad de Psicología, UNAM.

51. **Neurociencias Cognoscitivas**
Responsable: Zainos Rosales Antonio Paulino.
Licenciatura en Psicología.
Facultad de Psicología, UNAM.

52. **Taller de Psicofisiología**
Responsable: Zainos Rosales Antonio Paulino.
Licenciatura en Psicología.
Facultad de Psicología, UNAM.

53. **Temas selectos en Psicobiolgía III**
Responsable: Zainos Rosales Antonio Paulino.
Licenciatura en Psicología.
Facultad de Psicología, UNAM.

Con participación de miembros del IFC

1. **Fisiología microbiana**
   Participa: González Pedrajo Bertha.
   Facultad de Química, UNAM.

2. **Genómica funcional 2**
   Participa: Furlan Magaril Mayra.
   Centro de Ciencias Genómicas, UNAM.

3. **Taller de Ciencias: Astroglia y el cerebro: funciones y enfermedades**
   Participa: López Huerta Violeta Gisselle.
   Luis Baltazar Enoch.
   Hernández Cruz Arturo.
   Picones Medina Arturo.
   Facultad de Ciencias, UNAM.

4. **Genética**
   Participa: Furlan Magaril Mayra.
   Álvarez Adrián Fernando.
   Facultad de Medicina, UNAM.

5. **Taller de Neurobiología del aprendizaje y la memoria**
   Participa: Osorio Gómez Daniel.
   Facultad de Ciencias, UNAM.

6. **Aplicaciones de bioquímica y biología molecular**
   Participa: Valdés Rodríguez Víctor Julián.
   Torres Quiroz Francisco.
   González Pedrajo Bertha.
   Facultad de Química, UNAM.

7. **Inmunología**
   Participa: Licona Limón Paula.
   Instituto de Investigaciones Biomédicas, UNAM.

8. **Mecanismos que participan en la regulación de la traducción de proteínas**
   Participa: Martínez Silva Ana.
   LBB, UNAM.

9. **Taller de Titulación Biofísica de células excitables**
   Participa: Jiménez Pérez Nicolás.
   Licenciatura en Biología de la Facultad de Ciencias, UNAM.

10. **Métodos computacionales I: Métodos numéricos**
    Participa: Laville Conde Antonio.
    Facultad de Medicina, UNAM.

11. **Taller introductorio al análisis de la actividad eléctrica cerebral**
    Participa: Méndez Ambrosio Bruno.
    Facultad de Psicología, UNAM.

12. **Métodos en Neurociencias**
    Participa: Méndez Ambrosio Bruno.
    Facultad de Psicología, UNAM.

13. **Farmacología**
    Participa: Moncada Hernández Sandra.
    Facultad de Medicina, UNAM.

14. **Curso teórico-práctico: Técnicas en Sistemática Molecular de Plantas**
    Participa: Ongay Larios Laura.
    Instituto de Biología, UNAM.

15. **Taller Nivel III y IV. Caracterización de las Pirofosfatasas de proteobacterias**
    Participa: Peña Segura Claudia.
    Facultad de Ciencias, UNAM.

16. **Taller Neurobiología Sensorial**
    Participa: Sánchez Chávez Gustavo.
    Licenciatura en Biología.
    Facultad de Ciencias, UNAM.

Cursos de Posgrado

Miembros del IFC como responsables

1. **Bases moleculares de la síntesis de proteínas**
   Responsable: Pérez Martínez Xochitl.
   Posgrado en Ciencias Biomédicas.
   Instituto de Fisiología Celular, UNAM.

2. **Biofísica de la actividad eléctrica celular**
   Responsable: Gómora Martínez Juan Carlos.
   Posgrado en Ciencias Biomédicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Sotres Bayón Francisco
   Velasco Torres Myrian
   Hernández Cruz Arturo
   Galarraga Palacio Elvira
   Fernández de Miguel Francisco
   Méndez Ambrosio Bruno
   Laville Conde Juan Antonio

3. **Biología estructural de las membranas celulares**
   Responsable: González Halphen Diego.
   Posgrado en Ciencias Biomédicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Funes Soledad

4. **Biología molecular**
   Responsable: Recillas Targa Félix.
   Posgrado en Ciencias Biomédicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Torres Larios Alfredo
   Álvarez Adrián Fernando
   Furlan Magaril Mayra

5. **Biología molecular**
   Responsable: Funes Soledad.
   Posgrado en Ciencias Bioquímicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Valdés Rodríguez Víctor Julián

6. **Biología molecular**
   Responsable: González Pedrajo Bertha.
   Posgrado en Ciencias Bioquímicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Coria Ortega Roberto
   Aguirre Linares Jesús
   Ongay Larios Laura María
   De la Mora Bravo Francisco Javier
   Georgellis Dimitris

7. **Biología molecular de la célula eucarionte**
   Responsable: Castro Obregón Susana.
   Posgrado en Ciencias Biomédicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Silva Marina Macías
   Funes Soledad
   Torres Quiroz Francisco
   Escalante Alcalde Diana
   Peraza Reyes Leonardo
   Mas Oliva Jaime
   Hansberg Torres Wilhelm

8. **Bioquímica**
   Responsable: Torres Larios Alfredo.
   Posgrado en Ciencias Bioquímicas.
   Instituto de Fisiología Celular, UNAM.

   Participantes:
   Licona Limón Paula

9. **Bioquímica**
Responsable: García Sáinz Jesús Adolfo.
Posgrado en Ciencias Bioquímicas.
Facultad de Química, UNAM.

Participantes:
Macías Silva Marina

10. **Bioquímica**
Responsable: Pérez Martínez Xochitl.
Posgrado en Ciencias Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Torres Quiroz Francisco
Pérez Montfort Ruy

11. **Canales iónicos: Máquinas moleculares**
Responsable: Rosenbaum Emir Tamara.
Posgrado en Ciencias Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Llorente Gil Itzel Alejandra
Morales Lázaro Sara Luz
Arciniega Marcelino

12. **Células troncales: repercusiones en biomedicina**
Responsable: Velasco Velázquez Iván.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Navarro González Rosa
Valdés Rodríguez Víctor Julián
Furlan Magaril Mayra

13. **Tópico Selecto: Bases conceptuales de la epigenómica**
Responsable: Recillas Targa Félix.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Furlan Magaril Mayra
Poot Hernández Augusto César

14. **Optogenética: conceptos y aplicaciones**
Responsable: Tecuapetla Aguilar Fatuel.
Posgrado en Ciencias Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
López Huerta Violeta Gisselle
Velasco Torres Myrian
Ramírez Jarquín Josué Orlando

15. **Papel de los rearreglos genómicos como generadores de diversidad genética**
Responsable: González Manjarrez Alicia.
Posgrado en Ciencias Biomédicas.
Instituto de Investigaciones Biomédicas, UNAM.

16. **Fisiopatología del síndrome metabólico y la diabetes**
Responsable: Velasco Torres Myrian.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

17. **Neurobiología del aprendizaje y la memoria**
Responsable: Osorio Gómez Daniel.
Posgrado en Ciencias Biológicas.
Instituto de Fisiología Celular, UNAM.

18. **Modulación de la transmisión sináptica en sistema nervioso central y periférico**
Responsable: Hernández Cruz Arturo.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

19. **Neuroquímica básica**
Responsable: Massieu Trigo Lourdes.
Morán Andrade Julio.
Posgrado en Ciencias Biomédicas/Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Velasco Velázquez Iván
Tecuapetla Aguilar Fatuel
Sotres Bayón Francisco
Bargas Díaz José
Ramiro Cortés Yazmín

20. **Técnicas selectas de biología molecular**
Responsable: Torres Quiroz Francisco.
Posgrado en Ciencias Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Coria Ortega Roberto
Arciniega Castro Marcelino
Licona Limón Paula
Ongay Larios Laura María
Furlan Magaril Mayra
Moreno Alvarez Paola

21. **Uso e interpretación de la información tridimensional de macromoléculas, modelado y dinámica molecular**
Responsable: Arciniega Castro Marcelino.
Posgrado en Ciencias Bioquímicas.
Instituto de Fisiología Celular, UNAM.

Participantes:
Torres Larios Alfredo

22. **Comunicación nerviosa**
Responsable: Fernández de Miguel Francisco.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

23. **Diplomado en Biología molecular.**
Responsable: Contreras Zentella Martha Lucinda.
Posgrado en Ciencias Médicas Odontológicas y de la Salud.
Facultad de Odontología, UNAM.

24. **Biología molecular I**
Responsable: Contreras Zentella Martha Lucinda.
Posgrado en Ciencias Médicas Odontológicas y de la Salud.
Facultad de Odontología, UNAM.

25. **Biología molecular II**
Responsable: Contreras Zentella Martha Lucinda.
Posgrado en Ciencias Médicas Odontológicas y de la Salud.
Facultad de Odontología, UNAM.

26. **Curso Algoritmos Bioinspirados y Bioinformática.**
Responsable: Poot Hernández Augusto César.
Posgrado en Ciencia e Ingeniería de la Computación.
Instituto de Investigaciones en Matemáticas Aplicadas y en Sistemas, UNAM.

Con participación de miembros del IFC

1. **Bioenergética mitocondrial**
   Participa: Uribe Carvajal Salvador.
   Pérez Martínez Xochitl.
   Posgrado en Ciencias Biomédicas.
   Facultad de Medicina, UNAM.

2. **Biología molecular**
   Participa: Peraza Reyes Leonardo.
   Torres Quiroz Francisco.
   Furlan Magaril Mayra.
   Posgrado en Ciencias Bioquímicas.
   Instituto de Investigaciones Biomédicas, UNAM.

3. **Biología molecular aplicada para el estudio de la regulación genética en eucariontes**
   Participa: Morales Lázaro Sara Luz.
   Escalante Alcalde Diana.
   Posgrado en Ciencias Biológicas.
   Instituto de Fisiología Celular, UNAM.

4. **Bioquímica avanzada**
   Participa: Pérez Martínez Xochitl.
   Posgrado en Ciencias Biológicas.
   Facultad de Ciencias, UNAM.

5. **Creadores de la ciencia moderna**
   Participa: González Halphen Diego.
   Posgrado en Ciencias Biomédicas.
   Instituto de Neurobiología, UNAM.

6. **Cristalografía de macromoléculas**
   Participa: Torres Larios Alfredo.
   Posgrado en Ciencias Biomédicas.
   Instituto de Química, UNAM

7. **Fundamentos de células troncales, ingeniería tisular y medicina regenerativa**
   Participa: Velasco Velázquez Iván.
   Maestría y Doctorado en Ciencias de la Producción y de la salud animal.
   Facultad de Medicina Veterinaria y Zootecnia, UNAM.

8. **Inmunología avanzada: Moléculas de la respuesta inmune**
   Participa: Torres Quiroz Francisco.
   Posgrado en Ciencias Biomédicas.
   Facultad de Medicina, UNAM.

9. **Neurobiología celular y neurodesarrollo**
   Participa: Massieu Trigo Lourdes.
   Instituto de Neurobiología, UNAM.

10. **Neurodegeneración y deterioro cognitivo**
    Participa: Osorio Gómez Daniel.
    Posgrado en Ciencias Biológicas.
    Instituto de Fisiología Celular, UNAM.

11. **Proteínas: Estructura, estabilidad y función**
    Participa: Torres Larios Alfredo.
    Posgrado en Ciencias Biomédicas.
    Instituto de Química, UNAM.

12. **Regulación de la expresión génica en bacterias**
    Participa: Georgellis Dimitris.
    Posgrado en Ciencias Biomédicas.
    Centro de Ciencias Genómicas, UNAM.

13. **Relación de estructura-función de proteínas de membrana**
    Participa: González Halphen Diego.
    Posgrado en Ciencias Biomédicas.
    Instituto de Neurobiología, UNAM.

14. **Respuesta a proteínas mal plegadas en cáncer**
    Participa: Massieu Trigo Lourdes.
    Posgrado en Ciencias Biológicas.
    Instituto de Investigaciones Biomédicas, UNAM.

15. **Sistemas globales de regulación génica en bacterias**
    Participa: Georgellis Dimitris.
    Posgrado en Ciencias Bioquímicas.
    Instituto de Fisiología Celular, UNAM

16. **Temas selectos: Biología del envejecimiento**
    Participa: Licona Limón Paula.
    Posgrado en Ciencias Biológicas.
    UNAM

17. **Fundamentos de Biología Molecular**
Participa: Martínez Silva Ana Valeria.
Posgrado en Ciencias Biomédicas.
Instituto de Investigaciones Biomédicas, UNAM.

18. **Bioinformática y Biología Molecular de la Expresión Genética de un Organismo Extremófilo**
Participa: Ongay Larios Laura.
Posgrado en Ciencias Biológicas.
Instituto de Fisiología Celular, UNAM.

19. **Canales Iónicos: Bases y Metodologías para su Estudio**
Participa: Picones Medina Arturo.
Posgrado en Ciencias Bioquímicas.
Instituto de Biotecnología, UNAM.

20. **Biomembranas y Bioenergética, dentro del curso obligatorio de Bioquímica**
Participa: Sánchez Sánchez Norma.
Posgrado en Ciencias Bioquímicas.
Facultad de Medicina, UNAM.

21. **Bioenergética Mitocondrial**
Participa: Sánchez Sánchez Norma.
Posgrado en Ciencias Biomédicas.
Facultad de Medicina, UNAM.

22. **Introducción a las Neurociencias Cognitivas**
Participa: Zainos Rosales Antonio Paulino.
Posgrado en Ciencias Biomédicas.
Instituto de Fisiología Celular, UNAM.

Cursos de Licenciatura impartidos fuera de la UNAM

Con participación de miembros del IFC

1. **Transducción de señales**
   Participa: García Sáinz Jesús Adolfo
   Facultad de Medicina, Universidad Autónoma de San Luis Potosí.

2. **Seminarios para la Licenciatura en Ciencias**
   Participa: Castro Obregón Susana
   Centro de Dinámica Celular, Universidad Autónoma del Estado de Morelos.

3. **Técnicas de Biología Molecular 2**
   Participa: Mendoza Martínez Ariann Elizabeth.
   Universidad Autónoma Metropolitana (UAM)-Cuajimalpa.

4. **Curso- Taller Tópicos Selectos de Histotecnología**
   Participa: Rodríguez Montaño Sandra Daniela.
   Facultad de Ciencias Químicas.
   Universidad Autónoma Benito Juárez de Oaxaca U.A.B.J.O.

Cursos de Posgrado impartidos fuera de la UNAM

Miembros del IFC como responsables

1. **I Curso Internacional NeuroSur-CYTED "Nuevas Rutas de Señalización en Neurodegeneración"**
   Responsable: Castro Obregón Susana.
   Instituto de Investigaciones Científicas y Servicios de Alta Tecnología-AIP, Ciudad del Saber, Panamá.

2. **Taller. Fijación por perfusión para roedores**
   Responsable: Rosas Arellano Abraham.
   CINVESTAV- Instituto Politécnico Nacional.

3. **Curso Computación**
   Responsable: Poot Hernández Augusto César.
   Posgrado en Fisiología y Neurobiología Celular y Molecular.
   Departamento de Fisiología Biofísica y Neurociencias.
   CINVESTAV- Instituto Politécnico Nacional.

Con participación de miembros del IFC

1. **4º Diplomado de Bioética "Humanismo, cimiento de la salud". Interrupción legal del embarazo**
   Participa: Tapia Ibargüengoytia Ricardo.
   Hospital General Xoco, CDMX.

2. **Diplomado Bioética y Bioderecho, Estatus del embrión humano, células troncales y clonación**
   Participa: Tapia Ibargüengoytia Ricardo.
   Poder Judicial del Estado de Chihuahua y Colegio de Bioética. Chihuahua, Chih.

3. **Biología Molecular de Eucariontes**
   Participa: Recillas Targa Félix.
   Centro de Investigaciones de Estudios Avanzados (CINVESTAV) del IPN, Departamento de Biomedicina Molecular.

4. **Bioquímica Avanzada, con el tema cadena respiratoria y fosforilación oxidativa**
   Participa: González Halphen Diego.
   Departamento de Bioquímica, Escuela Nacional de Ciencias Biológicas, IPN.

5. **Cuso pre-congreso de la Rama de Transducción de Señales de la SMB. Clase: La citocina TGF-beta y la plasticidad celular**
   Participa: Macías Silva Marina.
   CINVESTAV-IPN y Sociedad Mexicana de Bioquímica, IPN.

6. **IBRO Course in Neuroscience**
   Participa: Fernández de Miguel Francisco.
   Universidad de Antioquía, Colombia.

7. **Neurociencias**
   Participa: Morán Andrade Julio.
   Universitat Autónoma de Barcelona.

8. **Biología Celular y Molecular**
   Participa: Chiquete Félix Natalia.
   ENCB-Instituto Politécnico Nacional.

9. **Bioinformatica**
   Participa: Guzmán León Simón.
   Programa de Maestría en Biología Molecular del Departamento de Genética y Biología Molecular del Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional.

10. **Regulación de la Expresión Genética**
    Participa: Funes Argüello Soledad.
    Departamento de Biología Celular del CINVESTAV-Zacatenco.

11. **Curso de Microscopia**
    Participa: Rincón Heredia Ruth
    Maestría en Ciencias del Departamento de Fisiología, Biofísica y Neurociencias del CINVESTAV- Instituto Politécnico Nacional.

12. **Microscopia (Teoría y Práctica)**
    Participa: Rosas Arellano Abraham.
    CINVESTAV- Instituto Politécnico Nacional.

Anexo 3

Ponencias

Participación en Congresos Nacionales

1. **2nd Epigenomics Meeting, 2019. Epigenetic Regulation in Human Disease. Instituto de Investigaciones Biomédicas, UNAM. 26-27 de septiembre 2019.**

   Ponencia:

   Valdés, Julián. “Epidermal Stem cell Differentiation”. 27-septiembre-2019.

   Cartel:

   Rodríguez Aguilera, J. R; Ecsedi, S; Goldsmith, C; Cros, M.P; Domínguez López, M; Guerrero Celis, N; Pérez Cabeza de Vaca, R; Chemin, R; Recillas Targa, F; Chagoya de Sánchez, V; Hernández Vargas, H. “Genome-wide 5-hydroxymethylcytosine emerges at early stage of in vitro hepatocyte differentiation”. 26-septiembre-2019.

2. **CEMUS XIV. Congreso de estudiantes de medicina del noroeste. Neurociencias. Universidad de Sonora.**
   30 de septiembre-4 de octubre 2019.

   Ponencia:

   Romo, Ranulfo. “Neurociencia y su impacto en las neuroprótesis”. 3-octubre-2019.

3. **III Neurobiology Meeting of the Mexican Society for Biochemistry. SMB. Guanajuato, México. 22-26 de septiembre 2019.**

   Ponencia:

   Alatriste León, Hector; Verma, Anil K; Ramírez Jarquín, Josué O; Tecuapetla Aguilar, Fatuel. “Perturbations in the Activity of Cholinergic Interneurons in the Dorsomedial Striatum Impairs the Encoding of an Instrumental Contingency Change”. 25-septiembre-2019.

   Escalante Alcalde, D; Cotzomi Ortega, I; Rivera Álvarez, J; Castro Hernández, R; Gómez López, S; Martínez Silva, V; Luna Leal, A. “Phospholipid phosphatase-3, a novel marker of neural stem cells, participates in the ventricular system remodeling and adult neurogenesis in mice”. 23-septiembre-2019.

   Romo, Ranulfo. “The neural code”. 25-septiembre-2019.

Montes Oca Balderas, Pavel; Gómora García, Juan Carlos; Massieu Trigo, Lourdes; Hernández Cruz, Arturo. “Effects of Anti-NMDA receptor antibodies on NMDA-induced intracellular Ca2+ rise: possible implications for anti-NMDAR encephalitis”. 23-septiembre-2019.

Violeta G. Lopez Huerta, Yinqing Li, Xian Adiconis, Kirsten Levandowski, Soonwook Choi, Mario A. Arias Garcia, Annie Y. Yao, Ralf D. Wimmer, Tomomi Aida, Alex Atamian, Tina Naik, Xuyun Sun, Dasheng Bi, Diya Malhotra, Marcos Gomes, Eunjin Hwang. “Integrated single-cell analysis reveals coupled molecular gradient and functional subnetworks in the thalamic reticular nucleus”. 24-septiembre-2019.

Morán, J; Cid Castro, C. “Role of ROS produced by mitochondria and NADPH-oxidase (NOX) in the apoptotic death of cerebellar granule neurons”. 22-septiembre-2019.

Sotrés Bayon, F. “Prefrontal "brake during conflict choice behavior”. 25-septiembre-2019.

Cartel:

Acevo Rodríguez, Pilar Sarah; Cabrera Benítez, Sandra; Escalante Alcalde, Diana; Castro Obregón, Susana. “The role of the autophagy during the early nervous system development”. 22-septiembre-2019.

Gómora García, Juan Carlos; Massieu Trigo, Lourdes. “Friend or Foe? Participation of IRE1 in the unfolded protein response induced by glucose deprivation in cortical neurons”. 23-septiembre-2019.

Gorostieta Salas, Elisa; Moreno Blas, Daniel; Domínguez Bautista, Jorge; Cisneros Vega, Bulmaro; Bermúdez Rattoni, Federico; Castro Obregón, Susana. “Autophagy induction reduces features of cellular senescence in the hippocampus of old rats”. 22-septiembre-2019.

Hüttenrauch, Melanie; Camberos Luna, Lucy Anita; Massieu Trigo, Lourdes; Castro Obregón, Susana. “Investigation of the therapeutic potential of autophagy induction in a mouse model of Alzheimer’s disease”. 23-septiembre-2019.

Jiménez Márquez, E; Ramiro Cortés, Y. “Neuronal activity in the primary visual cortex of SHANK3+/- in response to an over-specificity visual task”. 24-septiembre-2019.

Moreno Blas, Daniel; Gorostieta Salas, Elisa G; Muciño Hernández, Gabriel; Pommer Alba, Alexander M; Castro Obregón, Susana. “Neuronal Senescence is promoted by Dysfunctional Autophagy”. 22-septiembre-2019.

Ortiz Cruz, C.A; Ramiro Cortés, Y. “Behavioral correlates of atypical V1 neurons activity in a genetic mouse model of autism (SHANK3)”. 24-septiembre-2019.

Perera Murcia, G.R; Ramiro Cortés, Y. “Synaptic long-term depression mediated by mGlu and NMDA receptors in individual dendritic spines from SHANK3 mice”. 24-septiembre-2019.

Torres Esquivel, Carmen; Montiel Montes, Teresa; Flores Méndez, Marco; Massieu Trigo, Lourdes. “The Ketone body beta-hydroxybutyrate restores autophagic degradation in the brain of hypoglycemic rats”. 23-septiembre-2019.

Lara González. E; Duhne, M; Laville, A; Bargas, J. “Comparison of actions between L-DOPA and different dopamine agonists in striatal DA-depleted microcircuits in vitro: pre-clinical insights”. 24-septiembre-2019.

Duhne, M; Lara González, E; Laville, A; Padilla Orozco, M; Ávila Cascajares, F; Arias García, M; Galarraga, E; Bargas, J. “Activation of parvalbumin expressing neurons reconfigures neuronal ensembles in murine striatal microcircuits”. 24-septiembre-2019.

Alejandra Liliana Gómez Paz; Marcela Palomero Rivero; Diana Millán Aldaco; René Drucker Colín; Jose Bargas Diaz. “Allosteric modulation of nicotinic receptors reduces L-DOPA induced dyskinesias in parkinsonian mice”. 23-septiembre-2019.

Prior González, Mara; Lazo Gómez, Rafael; Tapia, Ricardo. “Inhibition of HDAC4 with sodium butyrate does not prevent AMPA-induced excitotoxic degeneration of spinal motoneurons *in vivo*”. 24-septiembre-2019.

Acosta Galeana, Isabel; Prior González, Mara; Tapia, Ricardo. “4-Aminopyridine protects against motor alterations in a chronic excitotoxic model of spinal motor neuron degeneration”. 24-septiembre-2019.

Díaz Hernández, Edgar Arturo; Sánchez Fuentes, Asaí; Ramírez Armenta, Kathia; Ramírez Jarquín, Josué Orlando; Tecuapetla Aguilar, Fatuel. “Thalamo-striatal contribution to switch between actions sequences”. 22-septiembre-2019.

Alatriste León, Héctor; Ramírez Jarquín, Josué Orlando; Tecuapetla Aguilar, Fatuel. “Striatal sub-circuits and cholinergic interneurons activity in behavioral flexibility”. 23-septiembre-2019.

Llanos Moreno, Argelia; Cuevas Vicente, Nisa; Alatriste León, Héctor; Valdez Fernández, Yiatzir; Ramírez Jarquín, Josué Orlando; Tecuapetla, Fatuel. “Optogenetic inhibition of the dorsomedial versus dorsolateral striatum”. 24-septiembre-2019.

Sánchez Fuentes, Asai; Ramírez Armenta, Kathia; Díaz Hernández, Edgar; Ramírez Jarquín, Josué Orlando; Tecuapetla, Fatuel. “Cortico–striatal contribution to execution of a chain of sequences”. 25-septiembre-2019.

Contreras López, Rubén Darío; Días Hernández, Edgar Arturo; Ramírez Jarquín, Josué Orlando; Tecuapetla, Fatuel. “Cerebellum–basal ganglia interactions circuits”. 26-septiembre-2019.

Emiliano Tesoro Cruz, Norma Oviedo De Anda, Leticia Manuel Apolinar, Sandra Orozco Suárez, Carolina Bekker Méndez, Gloria Martínez Pérez, Francisco Guerra Castillo, Chamina Aguirre Alvarado, Minerva Crespo Ramírez, Miguel Pérez de la Mora. “Ophthalmic administration of a DNA plasmid harboring the murine Tph2 gene: evidence for exogenous recombinant Tph2.FLAG in brain structures”. 22-septiembre-2019.

Hernández Mondragón Juan Carlos, Crespo Ramírez Minerva, Apolinar Manuel Leticia, Tesoro Cruz Emiliano, Pérez de la Mora Miguel. “Neuro-inmuno-endocrine changes induced by high-fat diet are associated with increased anxiety-like behavior in Wistar rats”. 22-septiembre-2019.

Medina Ruiz Gabriela Itzetl, Morán Julio. “Regulation of actin cytoskeleton by p47 overexpression in cerebellar granule neurons”. 23-septiembre-2019.

Diego Rolando Hernández Espinosa, Lourdes Massieu, Julio Morán. “Role of NADPH oxidase-2 in the progression of the inflammatory response secondary to striatum excitotoxic damage”. 24-septiembre-2019.

E. Colín, R. Tapia. “Chronic administration of glutamate decarboxylase inhibitors in the rat spinal cord induces motor alteration and motor neuron death”. 23-septiembre-2019.

4. **LXII Congreso Nacional de la Sociedad Mexicana de Ciencias Fisiológicas A.C. Universidad Autónoma de Querétaro. 12-15 de agosto 2019.**

Ponencia:

Bermúdez Rattoni, F. “Avances recientes en el estudio del aprendizaje y la memoria”. 14-agosto-2019.

Guzmán Ramos, K; Osorio Gómez, D; Rodríguez, F; Velasco, M; Bermúdez Rattoni, F; Hiriart, M. “Rescate de las alteraciones hipocampales asociadas al síndrome metabólico: participación dopaminérgica”. 13-agosto-2019.

Cartel:

Milo Rocha, Edgar Gerardo; Loza Huerta, Arlet; Lara Figueroa, Cesar Oliver; Picones, Arturo; Hernández Cruz, Arturo; Enoch, Luis. “Nuevos inhibidores del canal oncogénico de potasio Kv10.1”. 14-agosto-2019.

Cruz Cruz, Iskra Anai; Sánchez Zavala, José Hugo; Hiriart, Marcia; Velasco Torres, Myrian. “Efecto del síndrome metabólico en rata sobre el funcionamiento del canal KATP”. 12-agosto-2019.

Bernate Obando, Germán Alonso; Barajas Olmos, Francisco; Hiriart Urdanivia, Marcia; Velasco Torres, Myrian. “Los canales Kv2.1 y Kv2.2 y su regulación transcripcional en célula beta durante el desarrollo”. 12-agosto-2019.

Sánchez Soto, Carmen; Velasco, M; Chávez Maldonado, Juan Pablo; Hiriart Urdanivia, Marcia. “EL NGF plasmático aumenta durante el síndrome metabólico y viaja unido a sus dos receptores”. 12-agosto-2019.

Zavala Sánchez, José Hugo; Hiriart Urdanivia, Marcia; Sánchez Soto, María del Carmen; Velasco Torres, Myrian; Zambrano González, Elena. “El receptor soluble de insulina se encuentra aumentado en enfermedad de hígado graso no alcohólico”. 12-agosto-2019.

Cortes Escamilla, Cecilia Estrella; Sánchez Sandoval, Ana Laura; Gómora Martínez, Juan Carlos. “Participación de la subunidad NaVβ3 en la apoptosis de líneas celulares de cáncer”. 12-agosto-2019.

Elías López, Diana Lizbeth; Hernández Plata, Everardo; Gómora Martínez, Juan Carlos. “Evaluación electrofisiológica de antagonistas del canal NaV1.6 con potencial anti-metastásico en el cáncer cervico-uterino”. 12-agosto-2019.

5. **Taller Multidisciplinario de Redes. Taller de análisis de señales neurofisiológicas. Hotel Hacienda Cocoyoc, Morelos. 6-8 de noviembre 2019.**

Ponencia:

Miguel Serrano, Brisa García, Rosa María Reyes, Alejandra Cáceres, Elvira Galarraga, José Bargas. “Reconfiguración de ensambles neuronales durante eventos epileptiformes en la corteza motora del ratón”. 8-noviembre-2019.

Vladimir Calderón, Aldo Luna, Alejandra Gómez, Fernanda Ramírez, Elvira Galarraga, Jose Bargas. “Acciones de amantadina y clozapina en el microcircuito estriatal del ratón discinético”. 6-noviembre-2019.

Rossi Pool, R; Romo, R. “Código neuronal en la corteza somatosensorial secundaria (S2): dualidad sensorial y categórica” 7-noviembre-2019.

Montes Oca Balderas, Pavel; Gómora García, Juan Carlos; Massieu Trigo, Lourdes; Hernández Cruz, Arturo. “Efectos de anticuerpos anti-NMDA sobre la señal de iCa2+ inducida por NMDA: implicaciones para la encefalitis autoinmune por anticuerpos anti-NMDAR”. 8-noviembre-2019.

6. XLI Congreso Nacional de Microbiología y VI Congreso de Bioquímica y Biología Molecular de Bacterias. Oaxaca, México. 27-31 de octubre 2019.

Ponencia:

Vazquez Ciros, O. J; Rodríguez Rangel, C; Alvarez, A. F; Georgellis, D. "ZMP dependent activation of response regulators in Escherichia coli". 29-octubre-2019.

Hernández Valle, José; Sánchez Flores, Alejandro; Poggio, Sebastian; Dreyfus, Georges; Camarena, Laura. "The CtrA regulon of *Rhodobacter sphaeroides* favors adaptation to particular life styles". 27-octubre-2019.

Cartel:

Urias Contreras, F. A; Pannuri, A; Romeo, T; Alvarez, A. F; Georgellis, D. "Spatiotemporal regulation of the BarA/UvrY two component signaling system". 29-octubre-2019.

Marcos Vilchis, A.I; Espinosa Sánchez, N; González Pedrajo, B. "Substrate recognition by the sorting platform in the injectisome". 29-octubre-2019.

Vega Baray, B; Poggio, S; Dreyfus, G; Camarena, L. "Outer membrane vesicles from *Rhodobacter sphaeroides*". 29-octubre-2019.

Rodríguez Méndez, D; Domenzain, C; Poggio, S; Osorio, A; Dreyfus, G; Camarena, L. "Analysis of the FlgT-MotF interaction in the flagellar system 1 of *Rhodobacter sphaeroides*". 28-octubre-2019.

Vélez González, F; Vega Baray, B; Poggio, S; Dreyfus, G; Camarena, L. "Characterization of the open reading frame rsp_1315 present in the flagellar set 2 of *Rhodobacter sphaerodes*". 29-octubre-2019.

Benítez, J. M; González Vera, M; Poggio, S; Dreyfus, G; Camarena, L. "Expression of the Fla2 flagellin in *R. sphaeroides*: analysis of the control mechanisms". 28-octubre-2019.

Cruz Mendoza, L; de la Mora, F. J; Dreyfus, G. "Study of the motility of bacteria of the genus *Vibrio under* different salinity conditions". 29-octubre-2019.

Domenzain, C; Gómez César, E; Dreyfus, G; Poggio, S; Camarena, L. "CtrA regulation mediated by ClpXP in *Rhodobacter sphaeroides*". 29-octubre-2019.

Reyes Nicolau, J; Osorio, A; Domenzain, C; Poggio, S; Dreyfus, G; Camarena, L. "Evaluation of the open reading frame RSWS8N_09490 in the function of Fla2 of *Rhodobacter sphaeroides*". 29-octubre-2019.

7. **VII Congreso de Especies Reactivas del Oxígeno en Biología y Medicina SMB. Instituto de Investigaciones Biomédicas, UNAM. 9-11 de septiembre 2019.**

   Ponencia:

   Chagoya de Sánchez, Victoria. "Especies reactivas de oxígeno y nitrógeno en hepatotoxicidad: Cirrosis y Carcinoma hepatocelular". 9-septiembre-2019.

   Wilhelm Hansberg, Elisa Domínguez-Hüttinger **. "**Dioxygen Avoidance Theory: An experimentally validated mathematical model for the conidiation process in *Neurospora crassa*". 11-septiembre-2019.

8. **VII Congreso Nacional de la Rama de Transducción de Señales de la Sociedad Mexicana de Bioquímica. Centro Académico Cultural. Campus UNAM Juriquilla, México. 4-7 de noviembre 2019.**

   Ponencia:

   Ríos López, Diana; Ortega Domínguez, Bibiana; Aranda López, Yuli; Martínez Pastor, David; Macías Silva, Marina. "El contexto celular en la regulación transcripcional". 5-noviembre-2019.

Abstract: Metabolic overload by saturated fatty acids (SFA), which comprises β-cell function, and impaired glucose-stimulated insulin secretion are frequently observed in patients suffering from obesity and type 2 diabetes mellitus. The increase of intracellular Ca^{2+} triggers insulin granule release, therefore several mechanisms regulate Ca^{2+} efflux within the β-cells, among others, the plasma membrane Ca^{2+}-ATPase (PMCA). In this work, we describe that lipotoxicity mediated mainly by the saturated palmitic acid (PA) (16C) is associated with loss of protein homeostasis (proteostasis) and potentially cell viability, a phenomenon that was induced to a lesser extent by stearic (18C), myristic (14C) and lauric (12C) acids. PA was localized on endoplasmic reticulum, activating arms of the unfolded protein response (UPR), as also promoted by lipopolysaccharides (LPS)-endotoxins. In particular, our findings demonstrate an alteration in PMCA1/4 expression caused by PA and LPS which trigger the UPR, affecting not only insulin release and contributing to β-cell mass reduction, but also increasing reactive nitrogen species. Nonetheless, stearic acid (SA) did not show these effects. Remarkably, the proteolytic degradation of PMCA1/4 prompted by PA and LPS was avoided by the action of monounsaturated fatty acids such as oleic and palmitoleic acid. Oleic acid recovered cell viability after treatment with PA/LPS and, more interestingly, relieved endoplasmic reticulum (ER) stress. While palmitoleic acid improved the insulin release, this fatty acid seems to have more relevant effects upon the expression of regulatory pumps of intracellular Ca^{2+}. Therefore, chain length and unsaturation of fatty acids are determinant cues in proteostasis of β-cells and, consequently, on the regulation of calcium and insulin secretion.

Keywords: fatty acids; lipopolysaccharides; β-cells; proteostasis; insulin secretion

INFORME DE LABORES 2019

1. Introduction

Type 2 diabetes mellitus (T2DM) is a metabolic disorder characterized by dysfunction and progressive loss of pancreatic β-cells, which are responsible for insulin synthesis, originating tissue damage and several long-term complications [1]. This pathology could occur in conditions of obesity accompanied with a decrease in cellular response of insulin-dependent tissues. Phenomena such as β-cells proliferation and hyperinsulinemia seem to have a compensatory effect. However, these conditions possibly lead to β-cell dysfunction [2]. Indeed, in obesity and insulin resistance, β-cells are able to modulate the energetic metabolism in order to increase insulin synthesis and release [3].

Packaged in small granules, each β-cell has approximately 10,000 granules of insulin, of which only a fraction is released in response to an increase in glycemia [4–6]. After translation, pre-proinsulin polypeptides are translocated to the endoplasmic reticulum (ER) to acquire the native folding [7]. However, under conditions of high protein demand, ER stress is triggered. Therefore, the transducers of the unfolded protein response (UPR), IRE1, ATF6α, and PERK, promote the transcription and translation of target chaperones through XBPIs, ATF6α and CHOP transcription factors, respectively, when unfolded proteins accumulate in the lumen [8,9]. The three branches of UPR are essential in β-cells homeostasis to reduce ER stress and to ensure adequate synthesis of peptides such as insulin [6].

The key triggering factor for release of insulin granules is the increase of intracellular Ca^{2+}, associated with increased extracellular glucose [10]. Several mechanisms regulate the flux of Ca^{2+} in cells, such as the plasma membrane Ca^{2+}-ATPase (PMCA) and the Na^{+}/Ca^{2+} exchanger (NCX) [11]. PMCA belongs to the P-type ATPases whose function is critical to maintain the concentration of cytosolic calcium below 300 nM [12]; it is encoded by four different genes (*ATP2B1-ATP2B4*) and the isoforms expressed differentially in excitable and non-excitable cells [13,14]. On the other hand, the NCX uses the electrochemical Na^{+} gradient to export Ca^{2+} against gradient concentration [15]. Four isoforms have been identified for NCX (NCX1-4) and NCX1 is the most expressed in rat β-cells. The role of PMCA and NCX1 in β-cells is critical; both contribute to the extrusion of Ca^{2+}, therefore to the regulation of insulin release.

Lipotoxicity is associated with deleterious effects due to an increase of circulating fatty acids when the storage capacity of triglycerides in adipose tissue is overloaded. Indeed, lipotoxicity is related to β-cell dysfunction, wherein the capacity of protein folding may be compromised [16]. Lipotoxicity represses the protein trafficking from ER to the Golgi apparatus [17,18]. The palmitic (PA) and oleic (OA) fatty acids have been reported to induce apoptosis of β-cells, but only palmitic acid activates the PERK and IRE1 pathways [19]. Although the mechanism responsible for lipoapoptosis induced by ER stress is complex, it could involve alterations in Ca^{2+} [20]. Dysfunction of pancreatic β-cells has been associated with a low-grade inflammatory condition (meta-inflammation) associated with the excess of white adipose tissue in obesity [21]. It has been proposed that lipopolysaccharides (LPS) activate a signaling pathway mediated by TLR-4 [22], and this has been identified as a factor in obesity-associated metabolic disorders [23]. Additional evidence suggests that patients with T2DM show an altered intestinal microbiota in which Gram-negative bacteria predominate, then LPS, a critical component of its outer membrane, might promote inflammation [24]. Accordingly, the gut microbiota may play a role as a risk factor in the development of T2DM [25].

In this work, the effect of LPS on the UPR pathway in addition to free fatty acids was characterized, which modifies several key processes related to insulin secretion. Specifically, the properties that provide to fatty acids with their ER stress-inducing or protective role with a concomitant effect of LPS were described, through modulation of specific targets that regulate homeostasis of proteins (proteostasis), and then insulin secretion.

INFORME DE LABORES 2019

2. Materials and Methods

2.1. Reagents

RPMI-1640 medium (Gibco, Waltham, MA, USA), fetal bovine serum (FBS), penicillin, streptomycin, amphotericin B, palmitic acid (PA), oleic acid (OA), palmitoleic acid (PAO), stearic acid (SA), myristic acid (MA), lauric acid (LA), fatty acid-free bovine serum albumin (BSA) (Fraction V), lipopolysaccharides (from *Escherichia coli* O111:B4), trypsin, phosphate buffer saline (PBS), (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide (MTT) and tunicamycin (Tum) were obtained from Sigma-Aldrich.

2.2. Cell Culture

The established rat β-cell line RIN-m5F (American Type Culture Collection, ATCC, Manassas, VA, USA) was grown in RPMI-1640 medium supplemented with 10% FBS, 10 U/mL penicillin, 10 µg/mL streptomycin and 25 µg/mL amphotericin B. Cultures were maintained at 37 °C in a humidified atmosphere of 95% air and 5% CO_2. The culture medium was changed every 3 to 4 days and also passaged once per week, according to ATCC recommendations.

2.3. Fatty Acid and LPS Preparation

Stock solutions were prepared as follows: fatty acids were dissolved in ethanol:H_2O (1:1, vol:vol) at 60 °C at a final concentration of 75 mM. Stock solutions were complexed with fatty-acid-free BSA (3 mM in H_2O) by stirring for 1.5 h at 37 °C, then diluted in culture media and filtered by a 0.22-µm pore membrane. The final molar ratio of fatty acid:BSA was 4:1 with a final concentration of 300 µM BSA. LPS O111:B4 were dissolved in ultrapure water (1 mg/mL), and then diluted to a final concentration of 100 ng/mL, as previously reported [26].

2.4. Cell Viability Assays

Cell viability was evaluated using the MTT assay according to previous protocols [27]. Formazan crystals were dissolved in a lysis buffer containing 20% SDS and 50% N,N-dimethylformamide (pH 3.7) for 12 h at 37 °C, and absorbance readings were acquired at 560/530 nm.

2.5. Western Blotting Analysis

Proteins were extracted from cell cultures under different conditions, using ice-cold protein lysis buffer (150 mM NaCl, 10 mM Tris, pH 7.4, 1% Triton X-100, 0.5% NP40, 1 mM EDTA, 1 mM EGTA, 0.2 mM sodium orthovanadate, 10 mM benzamidine, 10 µg/mL leupeptin, 10 µg/mL aprotinin, and 250 µM PMSF). An average of 25 µg of protein samples from RIN-m5F cells were separated on 10% SDS-PAGE electrophoresis and transferred to polyvinylidene difluoride (PVDF) membranes. The membranes were blocked with 5% non-fat milk in Tris-buffered saline 0.1% Tween-20 (TBS-T) for 1 h at 37 °C, and incubated at 4 °C overnight with primary antibody (anti-XBP1s, anti-c-Jun, anti-ATF6α, anti-CHOP, anti-PMCA1/4, anti-Lamin-B, anti-β-adaptin, anti-BiP, anti-SPT, anti-SERCA2, anti-PMCA3, anti-NCX1, and anti-β-actin). Following washing with TBS-T, the membranes were further incubated for 1 h at 37 °C with the corresponding horseradish peroxidase-conjugated secondary antibodies. Proteins were detected with the enhanced chemiluminescence reagent (Immobilon Western from Millipore, Burlington, MA, USA).

2.6. Immunoprecipitations on Nucleus Extracts

Nuclei separation was carried out using a buffer containing sucrose (250 mM) and imidazole (3 mM) pH 7.4, supplemented with protease and phosphatase inhibitors. Cells were scraped from culture dishes and 21 passages were performed through a 22-G syringe. For the recovery of nuclei, lysates were centrifuged at 3400 rpm for 15 min. Then, nucleus fractions (200 µg) were incubated with

an anti-c-Jun antibody (1:400) for 2 h at 4 °C. Immune complexes were precipitated with protein G agarose Fast Flow (Millipore) 12 h at 4 °C. Immuno-precipitated proteins were washed 3 times and suspended in Laemmli buffer, separated by SDS-PAGE gels and transferred to PVDF membranes for Western-blot analysis. Protein detection was performed based on a previous protocol [26].

2.7. Insulin ELISA Assays

Cells were proliferated in 20 mm cell culture plates at a density of 2.3×10^5 cells/mL (2 mL). Cells were maintained in proliferation for 72 h, and later different treatments were performed on a volume of 1 mL. Cell culture medium was recovered, and centrifuged for 5 min at 5000 rpm. Supernatant medium was recovered and diluted (1/3) in PBS. Insulin concentrations were quantified with the Rat Ultrasensitive Insulin ELISA kit (80-INSRTU-E01, E10; ALPCO Diagnostics, Salem, NH, USA) through several adaptations according to manufacturer recommendations. Absorbance readings were performed at 450 nm, and results were reported as ng/mL.

2.8. Immunocytochemistry Assays

Treated cells were fixed in ethanol:acetone (1:1) at −20 °C and permeabilized with 0.01% Triton X-100. Slides were processed for immunocytochemical detection of transcription factors XBP1s and CHOP using the mouse/rabbit Polydetector HRP/DAB (BioSB, Santa Barbara, CA, USA). Slides were blocked with a horseradish peroxidase-conjugated antibody for 5 min and 1% bovine serum for 20 min, then incubated at 4 °C with the primary antibody. Following washing with PBS, the slides were further incubated for 40 min at room temperature with the secondary antibody. Immunostaining was performed with free-floating diaminobenzidine (DAB) for 2 min. After stopping the reaction, sections were embedded in Entellan and analyzed with the Axiovert.A1 FL-LED Microscope (Carl Zeiss, Oberkochen, Germany) and AxioCam ERc 5s (Carl Zeiss, Oberkochen, Germany). Image acquisition software ZEN-Blue edition was employed for image processing (Carl Zeiss, Oberkochen, Germany).

2.9. Fractionation of Cultured Cells and Determination of Triglycerides

Cells were processed as elsewhere reported [28]. Briefly, cells were washed with PBS 1×, scraped from the plate and transferred into a 2-mL tube, then centrifuged at 2000× *g* for 2 min. The pellet was resuspended in 200 µL of 60% sucrose dissolved in lysis buffer (10 mM HEPES and 1 mM EDTA, pH 7.4). After mixing, samples were incubated on ice for 10 min. Next, 800 µL of ice-cold lysis buffer was added, and incubated on ice for another 10 min. Cells were lysed by 5 passes through a 27-G needle and centrifuged at 100× *g* for 2 min. A mixture consisting of 2 µL of methylene blue mix per mL of lysis buffer was prepared. Then, 600 µL of this mixture were carefully layered on top of the cell homogenate and centrifuged at 20,000× *g* at 4 °C for 2 h. Tubes were frozen at −70 °C, the dye layer containing lipids (floating layer) was recovered by cutting the tube and transferred to a new tube where 100 µL of lysis buffer was added. Triglyceride content of fractions was measured using the Triglyceride-LQ kit (Giorna, Spain).

2.10. Calcium Quantification

Cells were processed according to a previous protocol [29] and intracellular calcium levels were calculated according to Patel et al. [30]. After treatments, cells were washed with PBS 1× and incubated at 37 °C with Opti-MEM/1.5 µM Fura-2/AM (fluorescent Ca^{2+} indicator) for 75 min. Subsequently, cells were washed with PBS 1× and incubated for 20 min at room temperature. Cells were washed with PBS 1×, and fluorescence measurements were carried out at 340 and 380 nm excitation wavelengths, and a 510 nm emission wavelength, employing a Cary Eclipse Fluorescence Spectrophotometer (Santa Clara, CA, USA).

2.11. Nitrite Assay

Nitrites were measured in the extracellular culture medium from treated cells as an index of reactive nitrogen species (RNS) formation, using the Griess reaction (40 mg/mL). Absorbance readings were performed at 450 nm in an ELISA plate.

2.12. Fluorescence-Probe Synthesis

Based in a methodology developed by our group, BODIPY (BDP) coupled to palmitic acid (BDP-PA), BODIPY coupled to stearic acid (BDP-SA), and BODIPY coupled to myristic acid (BDP-MA) were synthesized. Briefly, BODIPY-8-Ethylendiamine (0.436 mM) [31] in dichloromethane anhydrous (8 mL) was added to *N*′-ethylcarbodiimide hydrochloride (0.524 mM), hydroxybenzotriazole (0.524 mm), *N*-methylmorpholine (1.308 mM) and the corresponding fatty acid (0.48 mM). The mixture reaction was stirred for 5 h under argon atmosphere at 25 °C. Solvent was eliminated under reduced pressure, and the product was dissolved in water (20 mL) and extracted with dichloromethane. The combined organic extracts were washed with brine and dried over anhydrous Na_2SO_4, and later the product was concentrated. The crude product was purified by flash chromatography. All structures were confirmed by mass spectroscopy and nuclear magnetic resonance (NMR).

2.13. Confocal Microscopy

A LEICA TCS-SP8 confocal scanning biological microscope (LEICA Microsystems Heidelberg GmbH, Nussloch, Germany) was employed in order to characterize the BDP-MA, BDP-PA and BDP-SA sub-cellular localization. After different experiments with BDP-fatty acids (10–100 μM), cells were washed with PBS 1× 3 times, and then incubated with Aza-2-DBP for 30 min (0.8 μM). Later, cells were washed extensively and fixed with cold paraformaldehyde, and mounted for observation. Macroscopically different zones were recorded, preferentially at the center of the specimens, in order to depict representative images. Images were recorded at excitation/emission wavelengths of 488/495-545 and 638/650–750 nm for detection of BDP-fatty acids (green) and AZA-2-BDP (red), respectively.

2.14. Colocalization of ER-Tracker Probe and BDP-SFA

RIN-m5F cells were proliferated to 90% of confluence, and treated with BDP-PA (5–25 μM) for 12 h. Later, culture cells were washed with HBSS buffer and then ER-tracker (1 μM) was added and incubated for 25 min at 37 °C. Cells were washed once with HBSS buffer and fixed with 4% formaldehyde, for 2 min at 37 °C. Finally, cells were washed twice with PBS 1×. Images were recorded at excitation/emission wavelengths of 488/495-545 and 587/615 nm for detection of BDP-PA (green) and ER-tracker (red), respectively.

2.15. Quantitative PCR Methods

Total RNA from RIN-5mF cells was obtained with Trizol following the supplier's instructions. cDNA was synthesized using 1 μg of RNA and the iScript RT Supermix from Bio-Rad (Hercules, CA, USA). cDNA concentration was standardized to be used for qPCR with the PowerUp Sybr Green Master Mix 2X (Applied Biosystems) according to manufacturer's instructions. Primer sequences were: *RPL13*fwd 5′-AAAGCCTGCCAGAATTTCTCT-3′, *RPL13*rev 5′-GGGCTCCAAGGACTCTCTG-3′, *ATP2B1*fwd: 5′-GCAATTGAAAATCGCAACAA-3′; *ATP2B1*rev: 5′-TTCAGAGGCTGCATCTCCAT-3′; *ATP2B2*fwd: 5′-CGGAGTGTGGACTAAC AGCA-3′, *ATP2B2*rev: 5′-CTAGGGACTGCGTGACCAAG-3′; *ATP2B3*fwd: 5′-CAATCTTTCTA CCCCTACTCACATC; *ATP2B3*rev: 5′-GATGCAACTCTTGGATTCTGG; *ATP2B4*fwd: 5′-CTCTG AAAATCGCAACAAAGC-3′, *ATP2B4*rev: 5′-AGTGGCTGGATTTCCAAGG-3′. qPCR reactions were performed in triplicate using an ABI PRISM 7000. qPCR data were analyzed with the $2^{-\Delta\Delta Ct}$ method with *RPL13* (ribosomal protein L13) as reference calibrator, and reported as fold change.

INFORME DE LABORES 2019

2.16. Statistical Analysis

Data are expressed as mean ± SD. The statistical analyses were conducted with one-way ANOVA, and differences among means were compared with the Bonferroni test using a level of significance of $p < 0.001$ unless otherwise specified. The software used was GraphPad Prism version 6 (San Diego, CA, USA). For the analysis of the expression of proteins by Western blot, a semiquantitative analysis was performed using β-actin as loading control with the software ImageJ (Bethesda, MD, USA). Likewise, ImageJ was employed in the processing of immunocytochemistry results.

3. Results

First, we examined the effects of LPS upon the UPR pathway in β-cells. Although increasing concentrations of LPS did not modify cell viability (Figure 1A), LPS promoted an increase in the expression levels of transcription factors associated with diminishing ER stress, such as XBP1s and c-Jun. However, the ATF6α branch that showed a basal expression in the control condition showed a diminished expression by effect of LPS treatment (Figure 1B). Upon proving that LPS cause ER stress through the modification of the UPR pathway without affecting cell viability, we decided to evaluate the effect of the most representative saturated fatty acids (SFA). The four main saturated fatty acids (SFA) found in the phospholipid membranes and neutral lipids—lauric acid, myristic acid, palmitic acid, and stearic acid—were studied in order to characterize the role of the fatty acid acyl-chain length on β-cell physiology. In a first approach, we evaluated the effect of increasing concentrations of SFA (0–600 μM) on cell viability, considering a ratio of albumin/SFA of 1/4, which is in the range of reported plasmatic concentrations of fatty acids (350–500 μM) [32]. Results suggest PA as the most lipotoxic fatty acid, followed by SA, as demonstrated by the cellular viability measured by the MTT assay (Figure 1C), which is associated with mitochondrial activity. Although the UPR pathway was activated by the three SFA tested (Figure 1D), palmitic acid showed the major effect on CHOP expression. In this case, tunicamycin (Tun) was used as a positive control inducing ER stress, by inhibition of N-glycosylation protein process [33].

In order to evaluate the intracellular distribution of SFA, our working group carried out the chemical synthesis of three fluorescent probes to be tracked by confocal microscopy: BODIPY-PA (referred to as BDP-PA), BODIPY-SA (referred to as BDP-SA) and BODIPY-MA (referred to as BDP-MA). After the treatments, the internalization of BDP-PA (Figure 1F) was higher compared to detection with BDP-MA or BDP-SA (Figure 1E,G). This phenomenon supports the results obtained for cell viability, wherein PA was the most lipotoxic fatty acid.

PA is the most abundant SFA in the human body distributed in neutral lipids, the phospholipids of plasma membrane, organelles such as ER, and as a free fatty acid bound to albumin in plasma. Although the UPR activation by the three fatty acids was observed, PA treatment was more evident in the activation of UPR. In the endoplasmic reticulum, one-third of cellular proteins are synthesized, membrane and extracellular proteins are also folded, and, importantly, the ER is the main site of calcium storage [34,35]. In order to characterize the cellular distribution of PA, we employed the specific probe ER-tracker, performing the co-localization of ER-tracker (red channel) and BDP-PA (green channel) (Figure 2A–E). Results show that BDP-PA is located in the endoplasmic reticulum. In a complementary way, under a PA dose-dependent stimulus (0–600 μM), we corroborated the activation of IRE1 branch of the UPR through XBP1s expression (Figure 2G), and concomitantly the effect on insulin secretion function (Figure 2H). At 150 and 300 μM PA, the UPR activation was more evident, which agrees with the drop of cell viability observed previously.

INFORME DE LABORES 2019

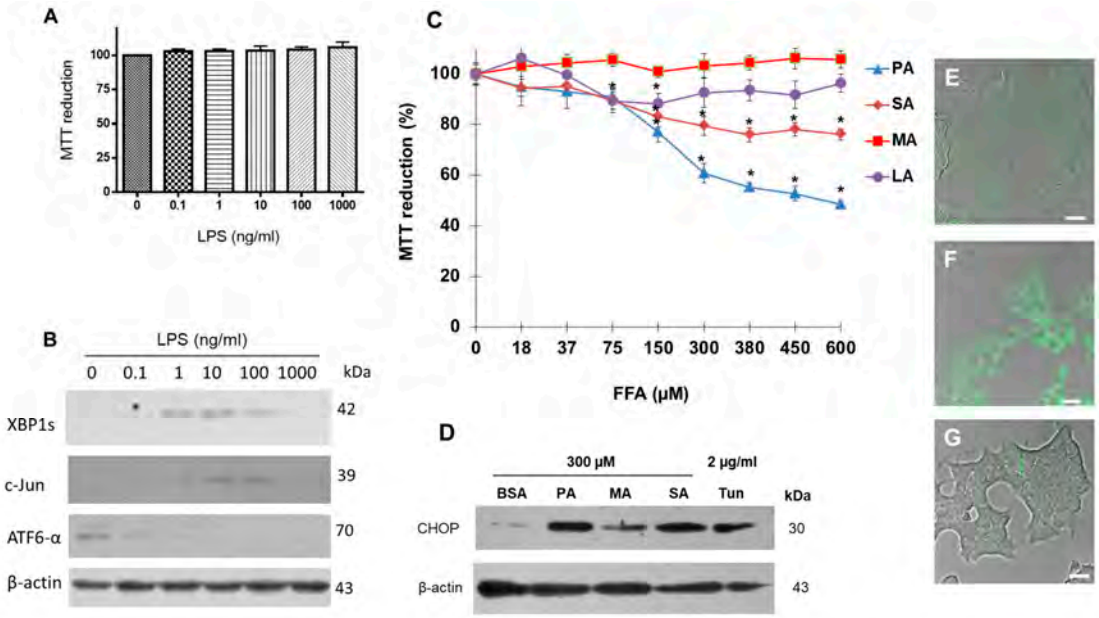

Figure 1. Lipopolysaccharides (LPS) and saturated fatty acids (SFA) trigger the unfolded protein response (UPR) pathway in β-cells, with 16C-pamitic acid (PA) the most lipotoxic. (**A**) Effect of increasing concentrations of LPS (0.1–1000 ng/mL) on cell viability. (**B**) Under the same conditions, expression of proteins XBP1s, c-Jun, and ATF6α analyzed by Western blot. (**C**) Effect of the treatment of saturated PA, stearic acid (SA), myristic acid (MA) and lauric acid (LA) (0–600 μM) on cell viability. (**D**) Effect of SFA treatment on CHOP expression. Tunicamycin (Tum) was used as a control. (**E**) Cellular distribution of BODIPY (BDP)-MA probe (green channel) (**E**), BDP-PA (**F**) and BDP-SA (**G**) in β-cells. Bars correspond to 20 μm. In panel B and D, β-actin was used as a loading control. In panel A and C, mean values are presented (n = 6, mean ± SD), * $p < 0.0005$ with respect to control.

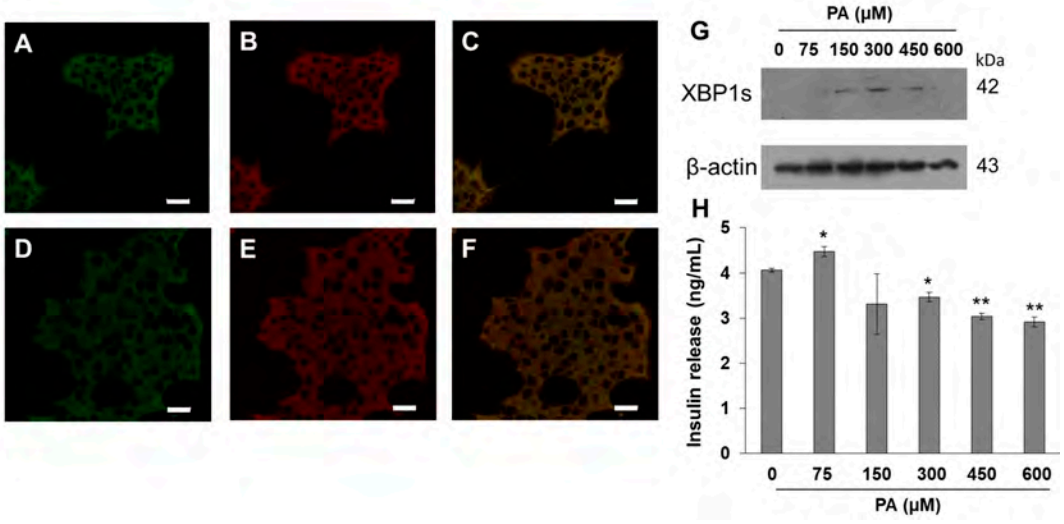

Figure 2. BDP-PA probe colocalizes with endoplasmic reticulum (ER)-tracker, and UPR is activated. (**A**,**D**) Confocal images of β-cells treated with BDP-PA (green channel). (**B**,**E**) Localization of ER-tracker probe (1 μM) (red channel). (**C**,**F**) Images corresponding to the merge. Bars correspond to 20 μm. (**G**) Under increasing concentrations of PA, UPR activation was evaluated through XBP1s activation, as well as the insulin release (**H**). Mean ± SD are presented (n = 3), * $p < 0.05$, **** $p < 0.005$.

Aiming to elucidate the combined effect of saturated fatty acids and LPS on cell viability as well as their intracellular location, which has not been described in the literature so far, β-cells were treated with PA and LPS. Cell viability was evaluated after a 24-h incubation with 300 μM palmitic

acid and 100 ng/mL LPS, and results show a significant decrease in cell viability, as compared to controls (Figure 3A). In addition, we characterized the intracellular distribution of BDP-PA probe and Aza-2-BODIPY (used as a counterstain; both were synthesized by our group). Interestingly, the counterstain probe Aza-2-BODIPY showed a cytoplasmic localization within the β-cells. By contrast, the BDP-PA signal was rather concentrated around the perinuclear area, wherein ER is localized, a phenomenon that was slightly increased under the treatment with LPS (Figure 3B–G). These results were corroborated, now employing the ER-tracker probe (Supplementary Figure S1).

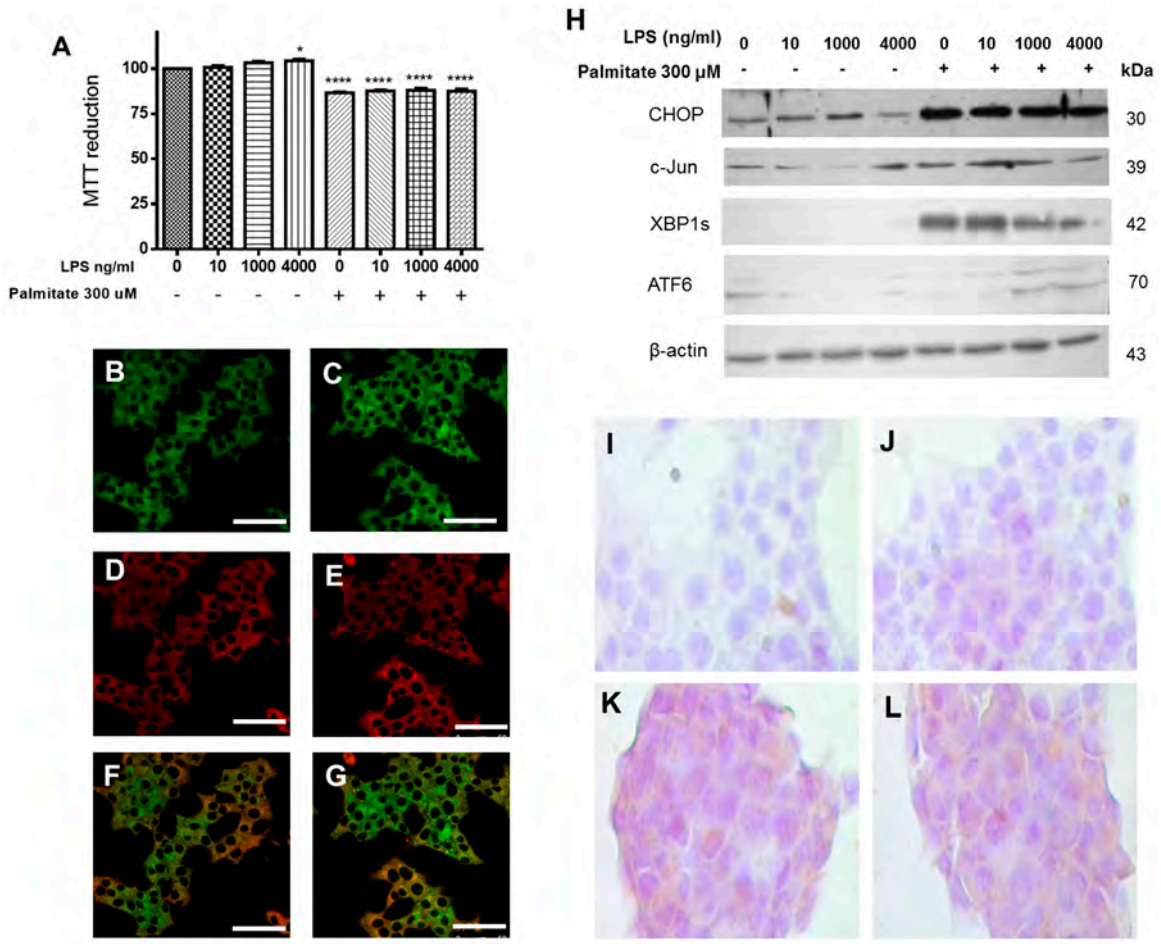

Figure 3. The combined treatment of LPS and PA potentiate the UPR activation in β-cells. (**A**) Effect of treatments with LPS and PA on cell viability ($n = 6$, mean ± SD), * $p < 0.05$, **** $p < 0.001$. Confocal images of β-cells treated with BDP-PA (**B**), Aza-2-BDP (**D**) and the merge (**F**). Under the same conditions, β-cells treated with BDP-PA plus LPS (**C**), Aza-2-BDP plus LPS (**E**), and the merge (**G**). Bars correspond to 50 µm. (**H**) Expression of CHOP, c-Jun, XBP1s, and ATF6α under increasing concentrations of LPS and PA (300 µM). β-actin was used as a loading control. (**I**,**J**) Detection of XBP1s by immunocytochemistry in control cells (negative signal). (**K**,**L**) Detection of XBP1s on PA-treated cells, positive signal (++) is determined by brown areas.

Although the LPS stimulus did not cause a decrease in cell viability, it slightly activated the UPR pathway through CHOP. However, when LPS and PA treatments were evaluated together, the UPR pathway was significantly activated by this transcription factor (CHOP). In parallel, it also increases the expression of XBP1s and ATF6a, as well as c-Jun (Figure 3H), which might be a possible response associated with the decrease in cell viability. Changes observed in cellular viability and the increase in XBP1s expression induced by PA agree with the analysis by immunocytochemistry of XBP1s (Figure 3I–L), where positive signals are observed as brown areas. Together, these data show

INFORME DE LABORES 2019

the activation of the UPR branches induced by LPS and the SFA most abundant in neutral lipids, as well as the ER localization of PA.

To assess if lipotoxicity could be extended to unsaturated fatty acids, the effect of oleic acid was evaluated. Unlike palmitic acid treatment, the exposure to OA neither modified the cell viability nor caused ER stress by activation of CHOP or XBP1s (Figure 4A,B). In this case, immunocytochemistry for CHOP in the presence of LPS and PA evidenced an increase in their expression (Figure 4C–F). Considering the stressor effect of palmitic acid and that OA did not produce ER stress, the possible protective or restorative role of OA was assessed under cytotoxicity induced by palmitic acid. With both fatty acids' stimuli, the effect of palmitic acid is reversed and cell viability is maintained (Figure 4G,H). Additionally, 12-h treatment with palmitic acid and followed by 12 h with OA alone, CHOP is not activated, but cell viability decreases (Figure 4H). However, treatment with OA prior to palmitic acid does not affect viability, but it activates CHOP, which may be a consequence of treatment with palmitic acid. These data suggest that OA could play a partial protective role.

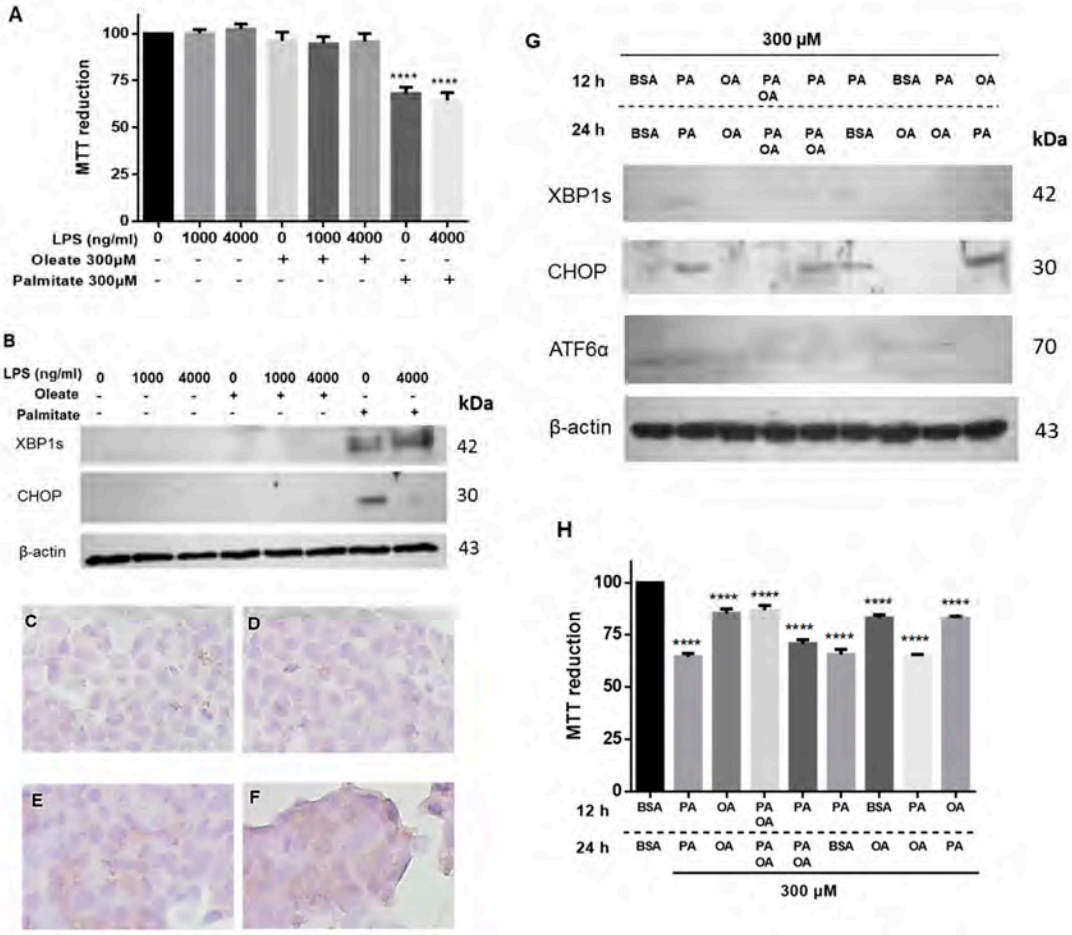

Figure 4. Oleic acid (OA) treatment does not trigger UPR and shows a partial protective role on lipotoxicity induced by PA. (**A**) MTT assay performed in β-cells exposed to different concentrations of LPS in the presence of 300 μM of PA or OA. (**B**) Under the same conditions, expression of XBP1s and CHOP. (**C**,**D**) Detection of CHOP by immunocytochemistry in control cells (negative signal). (**E**,**F**) Immunocytochemistry for CHOP under LPS and PA stimuli, positive signal (+) corresponds to brown areas. (**G**) Characterization of XBP1s, CHOP and ATF6α under a pre-treatment with fatty acids for 12 h, followed by the next treatment. (**H**) Under the same conditions, cell viability was characterized. β-actin was used as a loading control. In panel (**A**) and (**H**), (n = 6, mean ± SD), **** $p < 0.001$ with respect to control.

Aiming to evaluate one of the most relevant functions of β-cells, the insulin release, as we reported previously, we found a decrease in β-cell function with PA treatment, now using tunicamycin (Tum) as a control (Figure 5A). This characterization was complemented with the evaluation of CHOP, ATF6α and c-Jun in a time range (0–36 h), upon which a gradual activation was evidenced (Supplementary Figure S2). Considering that an increase of cytoplasmic [Ca^{2+}] in β-cells is the triggering factor for insulin release, a slight modification in PMCA expression isoforms 1 and 4 (PMCA 1/4) was observed (Figure 5B). Contrary to what was expected, the decrease in PMCA expression may favor an increase in insulin release due to a rise in intracellular [Ca^{2+}], however, other regulatory systems may be involved. The decrease in insulin secretion induced by PA matches with the cell viability decrease (Figure 5C). In order to broaden the effect of main saturated fatty acids, under a dose-dependent administration of PA, the decrease of PMCA1/4 expression was confirmed (Figure 5D), however, this change was not found in SA stimulus (Figure 5E). This phenomenon was supported through the UPR activation mediated by IRE1 only with PA treatment as previously described (Figure 2G), and not with SA treatment (Figure 5E).

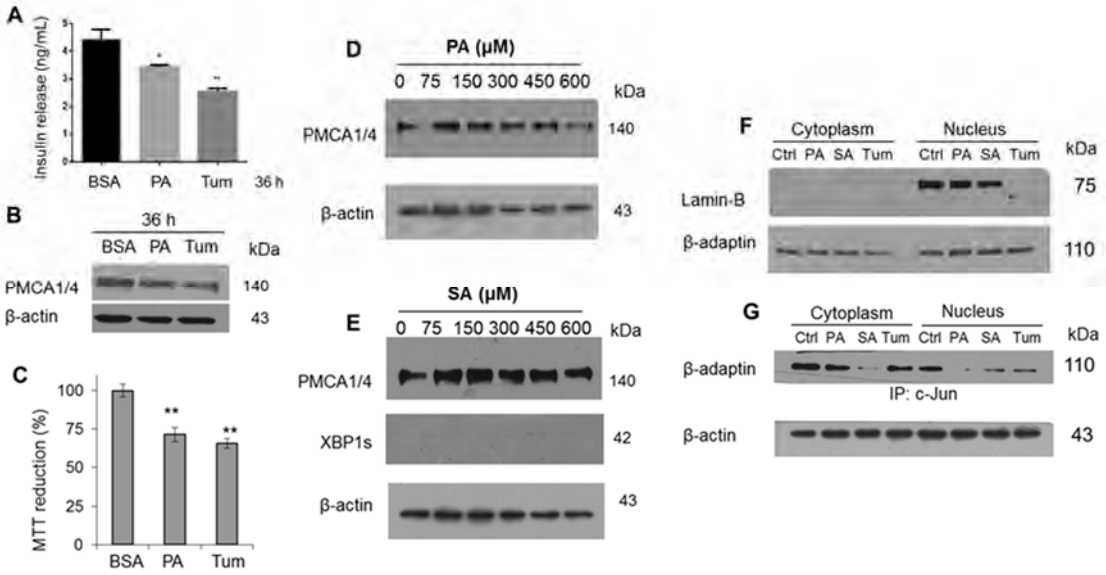

Figure 5. Endoplasmic reticulum stress reduces insulin secretion modifying the expression of PMCA1/4 and nuclear complexes. (**A**) Effect of treatment with PA and Tum on insulin secretion (n = 3, mean ± SD) * $p < 0.05$, ** $p < 0.01$. (**B**) Western blot characterization of PMCA1/4 isoforms. (**C**) Cellular viability assay, ** $p < 0.001$ with respect to control (n = 6, mean ± SD). Expression of PMCA1/4 and XBP1s in the presence of (**D**) PA or (**E**) SA. (**F**) Expression of Lamin-B and β-adaptin in nucleus extracts. (**G**) Evaluation of the complex formed by c-Jun and β-adaptin. β-actin was used as a loading control.

The specific case of the cytotoxicity exerted by Tum may be associated with an alteration in the nuclear structure (Figure 5F), considering the involvement of Lamin-B, a similar phenomenon that we have described in macrophages treated with LPS [36]. It should be noted that our group has described the function of new protein complexes formed by the adapter protein β-adaptin and transcriptional activators such as c-Myc and c-Jun that regulate the cell cycle and mechanisms such as endocytosis [36]. This condition was found to be affected in the nucleus under the stimuli with PA and Tum (Figure 5G), which we have correlated with the presence of an oxidative imbalance [37] implicating critical functions in the cells.

Expanding the characterization of this phenomenon, we found that stimulation with PA and LPS promotes the formation of RNS in the extracellular medium (Figure 6A). In a previous publication, we correlated the formation of RNS with the oxidative damage phenomenon and UPR activation in macrophages treated with LPS [36]. In our conditions, a drastic drop in insulin release was observed upon the treatment with palmitic acid and LPS (Figure 6B), associated with an increase in RNS

formation in the culture medium. In this case, the activation of BiP and XBP1s matches with an increase of nitrites (Figure 6C). Taking into account a partial protective function of OA under lipotoxicity conditions, the role of other unsaturated fatty acids such as PAO was evaluated. In both cases, the data suggest that treatment with unsaturated fatty acids prevents the drop of insulin release that is generated under the conditions of lipotoxicity by PA and LPS (Figure 6B). Interestingly, there is a mild increase of insulin release with PAO treatment with respect to controls. Data suggest that there is no metabolic effect that could modulate the treatment with unsaturated fatty acids, considering the quantification of triglycerides wherein only a slight increase in treatment of PA and LPS was registered, as well as the evaluation of targets such as serine palmitoyl-transferase (SPT), a key enzyme that uses palmitoyl-CoA and serine during ceramide synthesis (Figure 6D), which has been involved in several pathological diseases [38]. Then, our results suggest that under the cellular conditions evaluated, there was no significant metabolic alteration in β-cells.

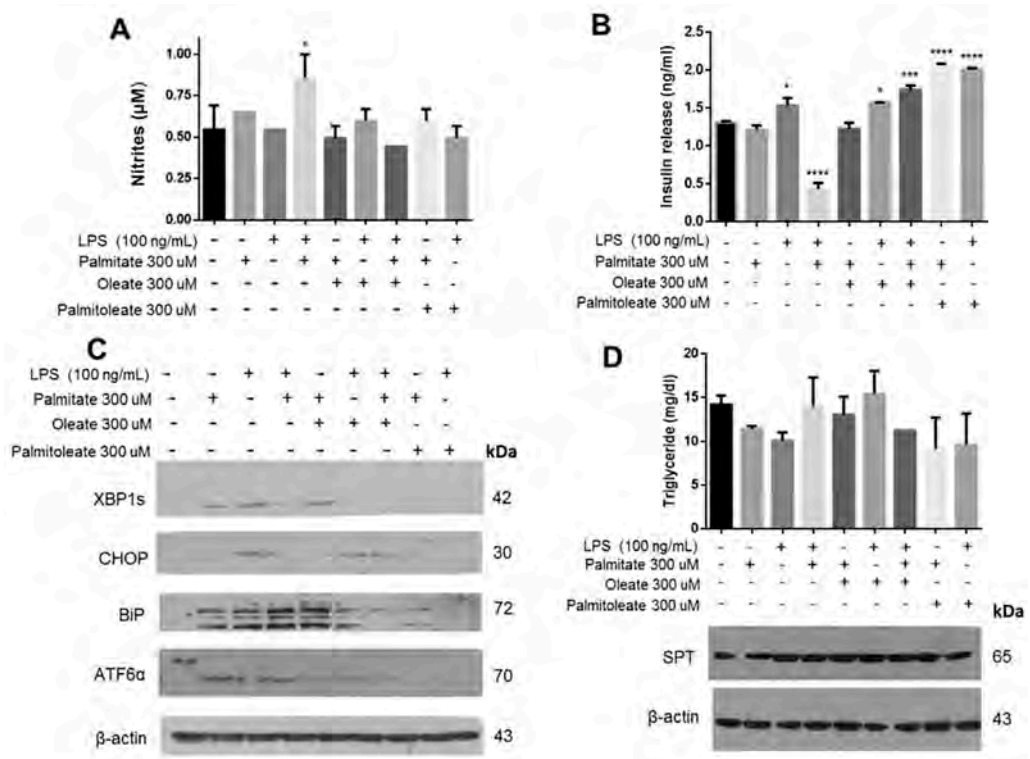

Figure 6. Unsaturated fatty acids could regulate the insulin secretion. (**A**) Quantification of nitrites in the extracellular medium under the incubation with several fatty acids and LPS. (**B**) Insulin secretion in cells exposed to the same treatments. (**C**) Western blot of UPR targets, XBP1s, CHOP, BiP and ATF6α. (**D**) Effect of treatments on metabolic regulation through intracellular quantification of triglycerides and evaluation of SPT. β-actin was used as a loading control. In panels (**A**) and (**B**), (n = 3, mean ± SD), * $p < 0.05$, *** $p < 0.01$, **** $p < 0.001$ compared to control.

To elucidate the correlation of the lipotoxicity phenomenon directly with the main β-cell function, the intracellular [Ca^{2+}] was evaluated under the same treatments (Figure 7A). We found that palmitic acid and LPS induced a decrease in [Ca^{2+}], which was demonstrated to be stabilized under incubation with oleic acid. Importantly, treatment with palmitoleic acid avoids the alteration in [Ca^{2+}] levels that induced the lipotoxicity. The most important proteins regulating intracellular [Ca^{2+}] were assessed, which in turn could explain this phenomenon. Importantly, a decrease in the expression of isoforms 1 and 4 of PMCA was induced by the presence of palmitic acid and LPS (Figure 7B). Although these isoforms maintain a ubiquitous expression, they show a low Ca^{2+} affinity in comparison to PMCA2 and PMCA3 isoforms [39]. Specifically, a second band of lower molecular weight was detected in the Western blot of PMCA1/4 (Figure 7B). This could suggest a proteolytic cleavage mediated by calpain,

which has been described to induce its degradation [40], as analyzed by our group in a previous work [41], therefore altering Ca^{2+} homeostasis, which affects key functions such as insulin secretion. Under our experimental conditions, the expression of PMCA3 in β-cells was undetectable (Figure 7B), although the expression of this isoform has been reported elsewhere [42]. The efficacy of the antibody was evaluated using brain tissue as a positive control where it is abundantly expressed, and in the liver tissue considering that the presence of transcripts has been reported before [43] (Figure 7D).

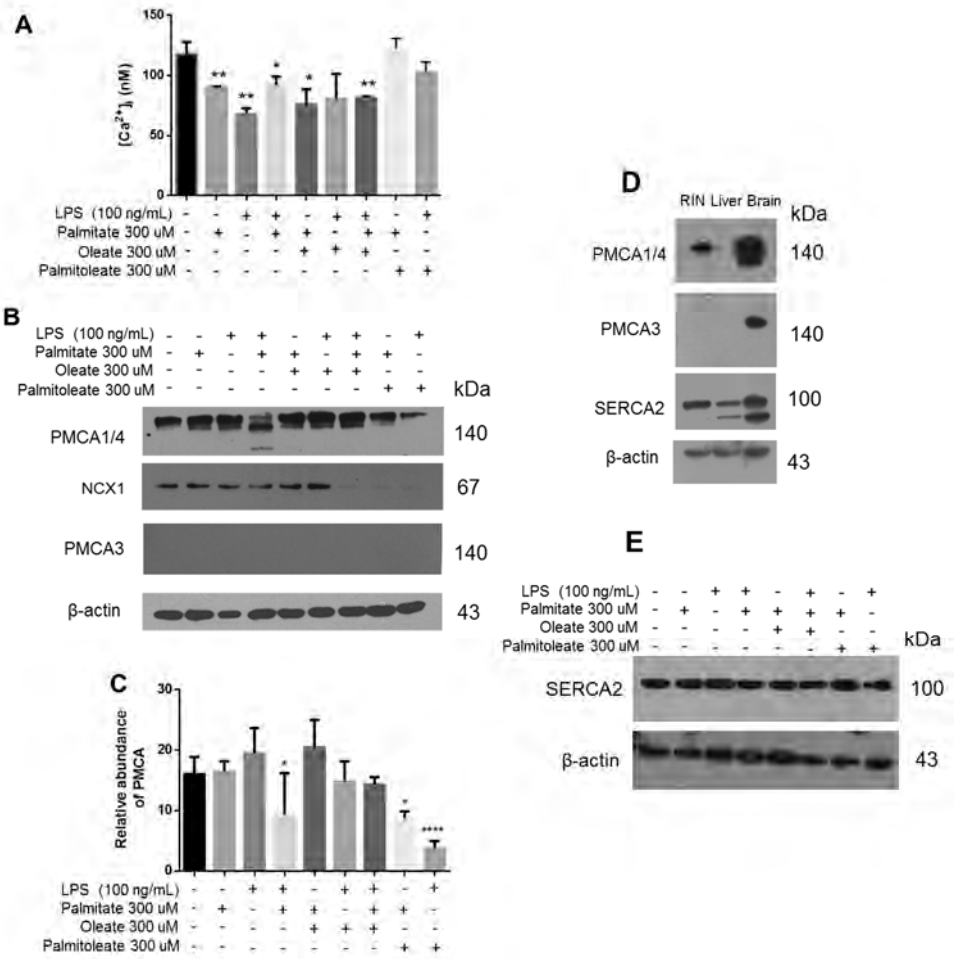

Figure 7. The treatment with unsaturated fatty acids regulates the expression of calcium transporting proteins. (**A**) Quantification of intracellular [Ca^{2+}] under lipotoxicity conditions. * $p < 0.05$, ** $p < 0.01$ compared to control ($n = 3$, mean ± SD). (**B**) Expression of targets PMCA1/4, NCX1 and PMCA3, which are regulated by oleic and palmitoleic acid. (**C**) Quantitative characterization of the expression of PMCA1/4, the analysis was based on three different experiments. * $p < 0.05$, **** $p < 0.001$ compared to control ($n = 3$, mean ± SD). (**D**) Validation of antibodies anti-PMCA1/4, anti-PMCA3 and anti-SERCA2 in RIN-m5F cells, liver and brain tissues. (**E**) Western blot of SERCA2. β-actin was used as a loading control.

Extending our characterization associated with PMCA1/4, the treatment with OA prevented the alteration of PMCA1/4 expression, which was evidenced through the statistical analysis (Figure 7C). However, a decrease in the expression of PMCA1/4 was found under PAO treatment, without evidence of degradation (Figure 7B). Furthermore, cytoplasmic Ca^{2+} levels were maintained at the same levels with respect to controls (Figure 7A). Notwithstanding this, under these conditions an increase in insulin release was recorded (Figure 6B). In order to expand the characterization of this phenomenon, other relevant proteins regulating intracellular [Ca^{2+}] were evaluated. A decrease in NCX1 expression was found under treatment with unsaturated fatty acids, which is responsible for Ca^{2+} output against the

gradient (Figure 7B). This phenomenon could represent a key condition in the regulation of insulin release. With respect to the evaluation of other targets, which could contribute to the explanation of the effect with unsaturated fatty acids, importantly, significant changes were not registered in the expression of SERCA2 (Figure 7E).

Taking into account these results, the role of SA, the second most abundant SFA in biological membranes, was evaluated. In particular, the stimulation with SA did not significantly decrease cell viability, contrary to what was observed with LPS, which caused a slight decrease in the viability (Figure 8A). In fact, insulin release is only modified under SA treatment (Figure 8B), and the incubation with PAO prevents this decrease and maintains insulin levels similar to controls. Under these same experimental conditions, PMCA1/4 expression remained constant (Figure 8C) and in none of the conditions, even upon treatment with SA and LPS, was a second band associated with the degradation of PMCA1/4 present; moreover, the PMCA3 isoform was not identified. An increase in insulin release was observed with the combination of PAO and SA, when compared with PAO. In order to extend this phenomenon associated with the maintenance of $[Ca^{2+}]$, no modifications were found in the SERCA2 expression. Remarkably, the cellular internalization of SA was diminished compared to PA (Figure 8D–I).

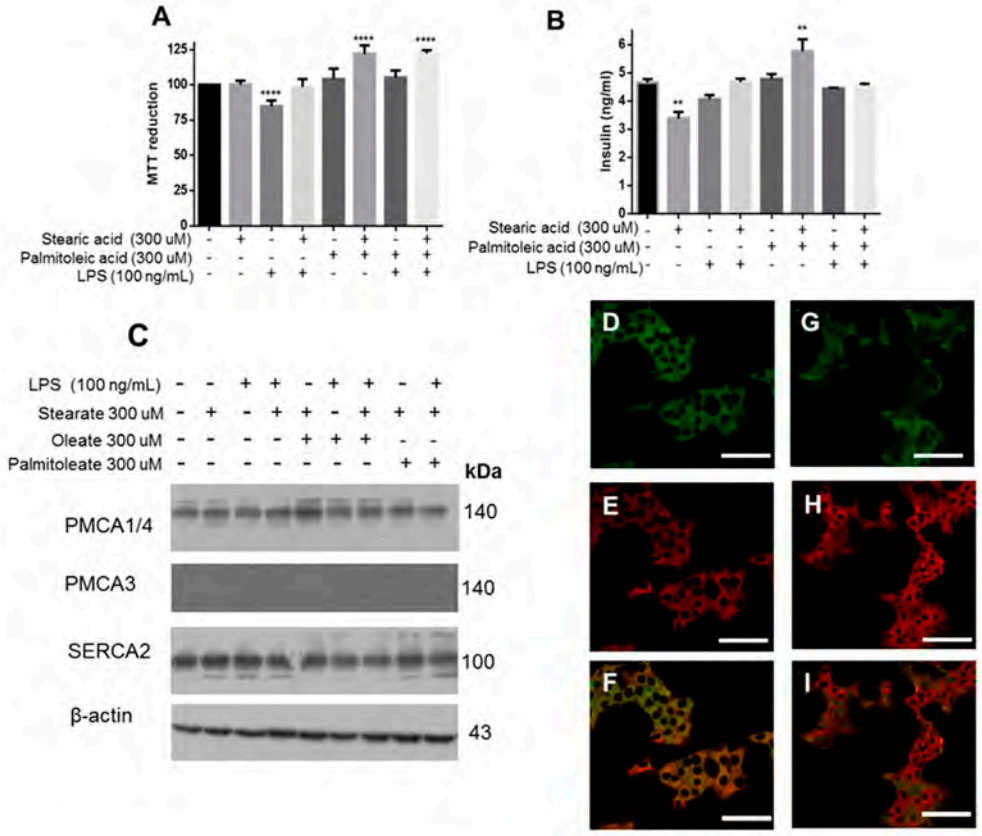

Figure 8. Stearic acid does not modify the homeostasis of calcium in β-cells. 4. Discussion

Considering that the ER lumen is the main site where protein folding and post-translational modifications take place, a decrease of insulin secretion attributed to fatty acid and LPS lipotoxicity could be identified by ER stress through UPR activation. Particularly, XBP1s is associated with the regulation of chaperones and protein degradation [44], relevant to mediate the ER stress that may be related to insulin processing. A similar pattern was observed in the activation of c-Jun, CHOP, and ATF6α transcription factors, which allow reduction of ER stress. Although in our conditions cell viability remains basal even in high concentrations of LPS, this could be associated with the fact that cells are trying to recover homeostasis by activating the UPR.

In an important manner, when main SFAs were evaluated, the most lipotoxic was PA (16C) which, according to our results, is mainly located in the endoplasmic reticulum. Although SA (18C), MA (14C) and LA (12C) were evaluated under the same conditions, possibly the length of PA is the optimal for recognition, and then for cellular internalization. In an attempt to extend the characterization of SFAs on key processes of β-cell physiology, our group has designed new materials based on surfaces functionalized with a layer of a fatty acid covalently bound. Results suggest that mainly PA affects the cell adhesion on surfaces compared to other saturated fatty acids (personal communication).

An association between ER stress and the development of DM2 has been previously described [45]. Nevertheless, no influence of SFAs and LPS on β-cell physiology has been reported hitherto. Our data suggest that LPS activated the UPR pathway, but did not reduce cell viability. However, cell viability was reduced significantly with PA and LPS stimuli, associated with cell internalization of the BDP-PA probe, activating the UPR pathway through CHOP, c-Jun, ATF6α and XBP1s. Considering that unsaturated fatty acids could prevent or even restore cell damage caused by lipotoxicity [46,47], our data suggest that oleic acid could have a partial protective role against lipotoxicity caused by PA/LPS. It is likely that a competition between oleic and palmitic acid for receptors such as FFAR1 or CD36 might occur; in fact, CD36 facilitates fatty acid transport and overexpression affects insulin secretion [48]. In an important way, we previously reported that small molecules with terpene structure could regulate ER stress induced by PA, through inhibition of the eukaryotic initiation factor-4A, with an effect in CHOP and XBP1s expression [49]. Therefore, protein translation is a target that could modulate ER stress induced by lipotoxicity.

Our results showed the activation of the UPR pathway by PA and its accumulation in organelle membranes, mainly in the ER area (Figures 2 and 3), generating stress conditions. Also, we observed a decrease in the PMCA1/4 expression, in correlation with an alteration of insulin secretion. It should be noted that the monoclonal antibody employed here recognizes isoforms 1 and 4, which show a ubiquitous expression. Although PMCA3 isoform has been detected specifically in β-cells by other authors [42], this is a controversial issue since we and others have not detected this isoform. In this work, PMCA3 was not detected at the protein level and, importantly, its absence was confirmed also when transcripts were measured by qPCR in all experimental conditions (data not shown). Regarding other PMCA transcripts expression, the observed pattern corresponds to the maximal expression of *ATP2B1* which is the most abundant in all tissues, but also when high intracellular [Ca^{2+}] levels are present. By itself, this finding can be related to the specific PMCA1 affinity for Ca^{2+} that is lower with respect to isoforms PMCA2 and PMCA3; when [Ca^{2+}] is elevated in the cytoplasm, cells do not require the function of the sensitive isoforms to extrude calcium, as we have observed before [14]. Since PMCA is responsible for intracellular Ca^{2+} removal and Ca^{2+} entry is a trigger factor for insulin release, a decrease in PMCA expression would be expected to generate the opposite effect. This may be due to other mechanisms responsible for [Ca^{2+}] regulation in the β-cells, such as the NCX1 exchanger and SERCA. The possibility of studying the expression of transcripts and activity of these proteins in the near future is open.

In our conditions, SERCA2 shows a basal expression, suggesting the importance of maintaining [Ca^{2+}] in the ER. Results suggest that there is not severe alteration in the ER. Importantly, the decrease in insulin release upon treatment with the PA/LPS was accompanied by the decrease in PMCA1/4

expression, wherein the detection of a lower molecular weight band of PMCA was a major finding. This effect could be correlated with the degradation of PMCA due to a proteolytic cleavage, a condition mediated by calpains and caspases under oxidative conditions [40], as corroborated by the formation of RNS. In this sense, a phenomenon related to oxidative phenomenon in β-cells is the lipid peroxidation by the generation of α, β-unsaturated 4-hydroxyalkenals (4-HNE, 4-HHE and 4-DDE) [50]. However, oleic and palmitoleic acid avoided this phenomenon, which could improve under the co-treatment with chalcone and flavone analogs recently synthetized by our group [51]. Interestingly, when the combination of palmitic acid plus LPS and the treatment with palmitoleic acid were tested, the UPR activation was minimal. Specifically, palmitoleic acid promoted an increase in insulin secretion without inducing CHOP over-activation, indicating a possible restorative role.

On the other hand, unlike palmitic acid, stearic acid alone did not cause severe ER stress and cell viability remained in basal conditions. In fact, treatment with SA and PAO increases cell viability; this was corroborated by the null modification in PMCA1/4 expression and insulin release. Therefore, we demonstrated that fatty acids exert a differential effect on the physiology of β-cells, with the length of the hydrocarbon chain a contributing factor. Palmitic acid caused the most harmful condition, affecting cell viability and activating the UPR pathway, wherein the saturation and, specifically, the 16C length chain are critical properties. Also, in combination with LPS, it generated a greater deleterious effect in all evaluated parameters: it decreased insulin release, promoted the proteolytic degradation of PMCA, and increased RNS. By contrast, SA did not cause any significant damage, but it decreased insulin secretion.

However, the effect of oleic acid and palmitoleic acid was different in insulin release, PMCA expression, and Ca^{2+} storage. Oleic acid had the ability to restore insulin release, but the expression of PMCA and NCX1 increased. Nevertheless, PMCA and NCX1 expression decreased with PAO/PA and PAO/LPS treatments, and insulin secretion increased maintaining the basal levels of Ca^{2+}. Therefore, oleic acid seemed to play a restorative role for the damage induced by SFAs, mainly ER stress, while palmitoleic acid improves insulin release and has more relevant effects upon intracellular calcium regulatory pumps.

Although free fatty acid proportions in the diet are a condition associated with the development of several diseases associated with alterations in metabolism [16,38,49], it is important to consider the adipose tissue as a buffering of lipid fluxes, which could be impaired in obesity by defects in response to the dynamic metabolism that occurs after meals [52], then modifying the relationship in concentrations of saturated/unsaturated plasmatic fatty acids. Therefore, the characterization of the main effects fatty acids have upon pancreatic β-cell physiology and the UPR pathway, and the repercussion on calcium homeostasis and insulin release, allow us to broaden our understanding of the different roles of fatty acids inside β-cells, which are important metabolites to take into account in explaining the damage and treatment of novel therapeutic targets in T2DM.

α_1-Adrenoceptors are seven transmembrane domain GPCRs involved in numerous physiological functions controlled by the endogenous catecholamines, noradrenaline and adrenaline, and targeted by drugs useful in therapeutics. Three separate genes, whose products are named α_{1A}-, α_{1B}-, and α_{1D}- adrenoceptors, encode these receptors. Although the existence of multiple α_1-adrenoceptors has been acknowledged for almost 25 years, the specific functions regulated by each subtype are still largely unknown. Despite the limited comprehension, the identification of a single class of subtype-selective ligands for the α_{1A}- adrenoceptors, the so-called α-blockers for prostate dysfunction, has led to major improvement in therapeutics, demonstrating the need for continued efforts in the field. This review article surveys the tissue distribution of the three α_1-adrenoceptor subtypes in the cardiovascular system, genitourinary system, and CNS, highlighting the functions already identified as mediated by the predominant activation of specific subtypes. In addition, this review covers the recent advances in the understanding of the molecular mechanisms involved in the regulation of each of the α_1-adrenoceptor subtypes by phosphorylation and interaction with proteins involved in their desensitization and internalization.

1 | INTRODUCTION

The actions of **adrenaline** and **noradrenaline** result from the activation of nine different **adrenoceptors**. All nine adrenoceptors belong to the superfamily of **GPCRs**, the most numerous family of membrane proteins (Fredriksson, Lagerstrom, Lundin, & Schioth, 2003; Fredriksson & Schioth, 2005). Adrenoceptors are classified into three subfamilies, α_1-, α_2-, and β- adrenoceptors, based on their pharmacological profiles, major coupling to signalling pathways (Hieble et al., 1995) and phylogeny. Using the latter criteria, adrenoceptors belong to the amine receptor cluster of the rhodopsin family (Fredriksson & Schioth, 2005) or to subfamily A, group 17 (Joost & Methner, 2002). For the accepted nomenclature, classification, databases, and other tools, see the following: IUPHAR/BPS guide for pharmacology (Harding et al., 2018; Sharman et al., 2018; and http://www.guidetopharmacology.org).

This review deals with advances in the function and regulation of each of the α_1-adrenoceptor subtypes; for additional aspects, readers are directed mainly to the reviews mentioned in this text, the references therein, and to Alexander et al. (2017).

2 | INTRACELLULAR SIGNALLING BY α_1-ADRENOCEPTOR SUBTYPES

The classical intracellular signalling pathway triggered by all three α_1-adrenoceptor subtypes results from coupling to $G_{q/11}$ proteins, leading to the activation of **phospholipase Cβ**, hydrolysis of phosphatidylinositol 4,5-bisphosphate into DAG/**inositol trisphosphate**, intracellular calcium mobilization, and **PKC** activation (Figure 1a; Hieble et al., 1995). Upon receptor activation, GPCR kinases (GRKs) and/or PKC phosphorylate α_1-adrenoceptors, leading to the recruitment of β-arrestins. Moreover, β-arrestins act as a scaffolding for other proteins triggering a distinct array of G-protein independent signalling through the activation of **ERK1/2** (Figure 1b; Perez-Aso et al., 2013; Segura et al., 2013).

It is worth mentioning that constitutive activity has been observed for native **α_{1D}- adrenoceptors** in rat arteries (Gisbert et al., 2002; Gisbert, Noguera, Ivorra, & D'Ocon, 2000; Noguera, Ivorra, & D'Ocon, 1996; Ziani, Gisbert, Noguera, Ivorra, & D'Ocon, 2002) and in cells overexpressing recombinant α_{1D}- adrenoceptors (García-Sáinz & Torres-Padilla, 1999; Rodríguez-Pérez, Romero-Ávila, Reyes-Cruz, & García-Sáinz, 2009); meanwhile, weak inverse agonism has been observed in some cells expressing native **α_{1A}-** or **α_{1B}- adrenoceptors** (Cotecchia, 2007). However, using site-directed mutagenesis, constitutively active mutants have been generated and inverse agonism has been detected (Cotecchia, 2007). Many of the currently used α_1-adrenoceptor antagonists are, in fact, inverse agonists (Cotecchia, 2007; García-Sáinz & Torres-Padilla, 1999; Rodríguez-Pérez et al., 2009).

3 | α_1-ADRENOCEPTORS IN PHYSIOLOGY AND PHYSIOPATHOLOGY

The α_1-adrenoceptor subfamily is composed of three members, that is, α_{1A}-, α_{1B}-, and α_{1D}- adrenoceptors (Hieble et al., 1995). These receptors participate in a large number of physiological processes and in the pathogenesis of diseases (for reviews, see García-Sáinz, Vázquez-Prado, & Medina, 2000; Garcia-Sainz, Vazquez-Prado, & Villalobos-Molina, 1999; Michelotti, Price, & Schwinn, 2000; Tanoue et al., 2003; Toews, Prinster, & Schulte, 2003). The latter has been regarded as the "dark side" of these transducers' actions, but, in our opinion, a better understanding of the molecular pharmacology of these receptors might lead to a path of light and hope, offering opportunities for novel therapeutic interventions. The sections below survey the roles of α_1-adrenoceptor subtypes in the cardiovascular system, genitourinary system, and CNS with regard to health and disease. Figure 2 summarizes some of the important functions controlled by α_1-adrenoceptor subtypes in these systems.

3.1 | α_1-Adrenoceptors in arteries

Among the best characterized α_1-adrenoceptor-mediated actions are those in the vascular system, where they are distributed across adventitial, medial smooth muscle, and endothelial cells (see McGrath, 2015). However, information on the role of each of the individual α_1-adrenoceptor subtype is limited to receptors expressed in vascular smooth muscle. Exceptions are the clear identification of **NO** production in endothelial cells from the rat aorta by α_{1A}- adrenoceptors (Arce et al., 2017), by α_{1B}-adrenoceptors in cultured endothelial cells from coronary arteries (Jensen, Swigart, Montgomery, & Simpson, 2010), and by α1D- adrenoceptors in endothelial cells from the rat mesenteric vascular bed and carotid artery (de Andrade et al., 2006; Filippi et al., 2001). With the increasing recognition of the importance of the perivascular adipose tissue for normal vascular function (Bulloch & Daly, 2014), it is expected that the roles of individual α_1-adrenoceptor subtypes in the tunica adventitia will be soon elucidated.

Although the vascular system expresses all three α_1-adrenoceptors, there is a predominance of specific subtypes in different arteries. An interesting view emerged in which the prevalence of an α_1-adrenoceptor subtype in a vessel depends on the density of sympathetic innervation and on the vessel calibre (Stassen, Maas, Schiffers, Janssen, & De Mey, 1998). The α_{1A}- adrenoceptors predominate in resistance arteries such as the small mesenteric artery (Marti et al., 2005; Methven, McBride, Wallace, & McGrath, 2009; Nourian et al., 2008; Philipp & Hein, 2004) and distributing arteries such as the renal (Hrometz et al., 1999) and tail (Kamikihara et al., 2005; Lachnit, Tran,

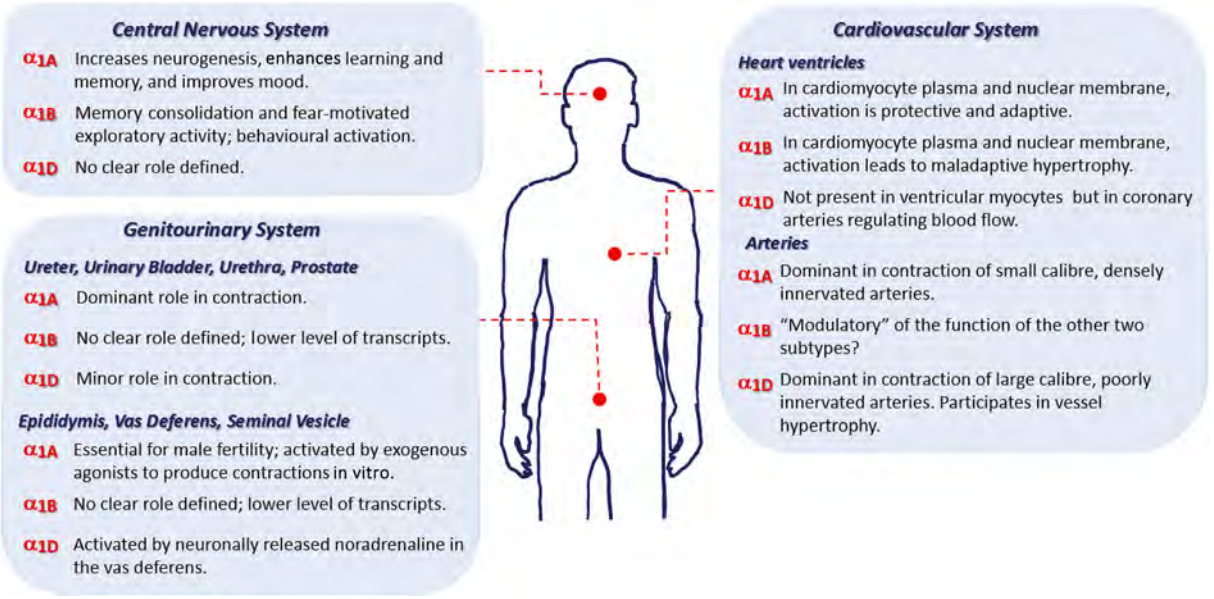

FIGURE 2 Summary of the main functions identified for each of the α_1-adrenoceptors subtypes in the cardiovascular system, genitourinary system, and CNS. Readers are referred to the text for the bibliography

Clarke, & Ford, 1997; Taki et al., 2004) arteries. Conversely, α_{1D}-adrenoceptors are more prevalent on less innervated conductance arteries including the aorta, femoral, iliac, carotid, pulmonary, and superior mesenteric arteries (Arevalo-Leon, Gallardo-Ortiz, Urquiza-Marin, & Villalobos-Molina, 2003; Gisbert et al., 2000; Hussain & Marshall, 1997; Marti et al., 2005; Methven, Simpson, & McGrath, 2009; Nourian et al., 2008; Piascik et al., 1995; Rudner et al., 1999). This differential distribution of α_{1A}-adrenoceptors indicates physiological relevance; the dominant α_{1D}- adrenoceptors in conductance arteries result in high sensitivity to catecholamines, and the activation of this subtype leads to persistent vasoconstriction that tends to continue even after agonist removal, preventing sudden changes in the vessel calibre during variations in the circulating levels of catecholamines (Flacco et al., 2013; Gisbert et al., 2000; Noguera et al., 1996; Ziani et al., 2002). On the other hand, in the more densely innervated smaller resistance arteries, noradrenaline released from sympathetic terminals activates α_{1A}- adrenoceptors and causes less sustained vasoconstriction allowing rapid vascular tonus adjustment in response to autonomic activation. The positive relationship between the density of adrenergic fibres and dominance of α_{1A}- adrenoceptors is reversible, as sympathetic denervation increases the expression and participation of the other two subtypes in vasoconstriction (Kamikihara et al., 2005; Kamikihara et al., 2007; Stassen et al., 1998; Taki et al., 2004). In addition, the potencies of antipsychotics in producing orthostatic hypotension correlated with their affinities for α_{1A}- adrenoceptors but not for α_{1D}- adrenoceptors (Nourian et al., 2008), as most of the antipsychotics behave as competitive antagonists of α_1-adrenoceptors, and this positive correlation further indicates that noradrenaline released from sympathetic terminals targets the α_{1A}- adrenoceptors to increase peripheral vascular resistance.

Whereas the roles of the α_{1A}- and α_{1D}- adrenoceptors in vasoconstriction were promptly recognized, evidence for the participation of α_{1B}-adrenoceptors is scarce. The lack of subtype-selective α_{1B}-adrenoceptor ligands limits the understanding of the role of this subtype in the vascular system. Nevertheless, studies in α_{1B}-adrenoceptor knockout mice indicate that this subtype plays a minor role in vascular homeostasis, acting mainly as a modulator of the other two receptors' activities (Cavalli et al., 1997; Cotecchia, 2010; Daly et al., 2002; Docherty, 2010; Tanoue et al., 2003).

In several animal models, hypertension has been associated with increased α_{1D}- adrenoceptor signalling (Gisbert et al., 2002; Ibarra, Terrón, López-Guerrero, & Villalobos-Molina, 1997; Villalobos-Molina et al., 2008; Villalobos-Molina & Ibarra, 1999; Villalobos-Molina & Ibarra, 2005; Villalobos-Molina, López-Guerrero, & Ibarra, 1999). Activation of α_{1D}-adrenoceptors increases protein synthesis and vascular wall growth (Erami, Zhang, Ho, French, & Faber, 2002; Xin, Yang, Eckhart, & Faber, 1997). In an **angiotensin II**-induced hypertension and aortic hypertrophy model, α_{1D}- adrenoceptor antagonists do not prevent hypertension, but do inhibit vascular hypertrophy, dissociating both events and suggesting a role for α_{1D}- adrenoceptors in the long-term vascular hypertrophic process (Gallardo-Ortiz et al., 2015).

The roles of catecholamines and α_1-adrenoceptors in pulmonary hypertension induced by chronic exposure to reduced oxygen was examined in wild-type (WT) and knockout mice. The decreased luminal area and increased wall thickness of the arteries induced by hypoxic conditions in WT mice were markedly reduced in **dopamine β-hydroxylase** knockouts as well as in α_{1A}- or α_{1B}-adrenoceptor-deficient mice, strongly suggesting that the activation of these receptors by noradrenaline/adrenaline contributes to the vascular remodelling in hypoxic pulmonary hypertension (Faber et al., 2007).

Although α_1-adrenoceptor antagonists are antihypertensive, orthostatic hypotension and the worsening of heart failure, along with the availability of better alternatives, have considerably decreased their prescription. Currently, the α_1-adrenoceptors in the vascular system

are targets for agonists to promote vasoconstriction. Thus, α_1-adrenoceptor agonists such as **phenylephrine**, are components of oral over-the-counter medications to alleviate the congestive symptoms of the common cold and influenza. In addition, the imidazolines, **oxymetazoline** and **naphazoline,** are common components of topical nasal decongestants, mydriatic eye drops, and more recently dermatological formulations for the treatment of facial erythema in rosacea (Kircik et al., 2018; Mota & Norris, 2016; Vaidyanathan, Williamson, Clearie, Khan, & Lipworth, 2010). Interestingly, oxymetazoline and naphazoline are low efficacy agonists with reasonable selectivity for α_{1A}- adrenoceptors (10- to 30-fold; Akinaga et al., 2013; Minneman, Theroux, Hollinger, Han, & Esbenshade, 1994), further supporting the relevance of this subtype in vasoconstriction. However, the prolonged use of these topical agonists is limited by tachyphylaxis leading to rebound congestion and hyperaemia, opening the possibility for the development of better agonists that are less tachyphylactic than those currently available.

Intravenous α_1-adrenoceptor agonists are indispensable medications in emergency and intensive care units to raise BP in shock (Colling, Banton, & Beilman, 2018; Jentzer et al., 2018). The most used α_1-adrenoceptor agonists to revert hypotension are noradrenaline, adrenaline, **dopamine,** and phenylephrine. Recently, a shortage in the noradrenaline supply to US hospitals was associated with increased mortality among patients with septic shock (Vail et al., 2017). In septic shock, reversal of hypotension with the currently available vasoconstrictors is limited by tachyphylaxis because vasoconstriction diminishes as treatment continues, resulting in inadequate blood perfusion and vital organ failure. It has been proposed that the loss of vasoconstriction due to α_1-adrenoceptor agonists in septic patients might result from receptor desensitization (Geloen et al., 2015; Hwang, Lau, Huang, Chen, & Liu, 1994), and again, the development of ligands that are less tachyphylactic than the natural catecholamines and phenylephrine would be a significant improvement in the emergency treatment of hypotension by providing more sustained elevation of BP.

3.2 | α_1- Adrenoceptors in the heart

α_1- Adrenoceptors participate in the development, growth, and function of the heart. Current evidence indicates that the α_{1A}- and α1B-adrenoceptors are present in the myocardium, modulating contractility, whereas the α_{1D} subtype is found in coronary arteries, regulating heart perfusion (O'Connell, Jensen, Baker, & Simpson, 2014). It has been recently proposed that all ventricular myocytes in the mouse heart express the α_{1B}-adrenoceptors (and β_1-adrenoceptors), whereas the α_{1A}- adrenoceptors are present in half of these cells and co-expressed with α_{1B}-adrenoceptors (Myagmar et al., 2017). These receptors also play an important role in cardiac hypertrophy (reviewed in Cotecchia, Del Vescovo, Colella, Caso, & Diviani, 2015; O'Connell et al., 2014; Woodcock, Du, Reichelt, & Graham, 2008). Cardiac hypertrophy is characterized by an abnormally large myocardial mass that reflects, among other changes, an increased cardiomyocyte size and is often accompanied by heart failure. The development of α_1-adrenoceptor-mediated cardiomyocyte hypertrophy depends on classical signalling through Gq proteins and, probably, through β-arrestins, leading to the activation of **MAPKs**, modulation of transcription factors, and ultimately to hypertrophy (Cotecchia et al., 2015; O'Connell et al., 2014; Woodcock et al., 2008). Interestingly, in addition to this canonical signalling pathway, there is evidence indicating that α_1-adrenoceptors are also present in cardiomyocyte nuclei, from where they signal likely through Gq, phospholipase Cβ, inositol trisphosphate, and calcium to induce hypertrophy (Dahl et al., 2018; O'Connell et al., 2014; Wu & O'Connell, 2015). This is an interesting new paradigm that might have important physiological and pharmacological implications, including ligand transport into the cells, ligand lipophilicity, and the possible roles of transporters (O'Connell et al., 2014).

Surprisingly, the activation of α_1-adrenoceptors appears to be beneficial for some cardiac conditions. This sounds counterintuitive and, in fact, runs contrary to some relatively recent medical ideas. Agonists of α_1-adrenoceptors ameliorate ischaemia reperfusion injury, chemotherapy-induced cardiotoxicity, and calcium overload, among other noxious events or drugs (reviewed in Jensen, O'Connell, & Simpson, 2011; Perez & Doze, 2011). Similarly, experimental and clinical trial data have suggested that α_1-adrenoceptor antagonists might worsen some cases of heart failure (Jensen et al., 2011). It has been suggested that α_1-adrenoceptor agonists could provide cardioprotection (Jensen et al., 2011; Perez & Doze, 2011), particularly those selective for the α_{1A} subtype (Cowley et al., 2017). Consistent with this, in transgenic mice adrenergic-induced ischaemic-preconditioning is mediated by α1A- adrenoceptors (Perez & Doze, 2011).

3.3 | α_1-Adrenoceptors in the genitourinary system: Ureter, urinary bladder, urethra, and prostate

Benign prostatic hyperplasia (BPH), an enlarged prostate frequently accompanied by lower urinary tract symptoms, such as acute urine retention, is very common in men 40 years old and older. The prostate expresses α_1-adrenoceptors, predominantly the α_{1A} subtype (Price et al., 1993; Faure, Pimoule, Vallancien, Langer, & Graham, 1994) and this subtype mediates prostate contraction (Forray et al., 1994), and the enlarged prostate compresses the urethra leading to difficulties in micturition. **Tamsulosin**, the first α_{1A}- adrenoceptor selective drug used to alleviate the symptoms of BPH, was a major step in improving the pharmacological treatment of patients. This and related drugs are recommended as first-line treatments for patients with BPH by medical associations (McVary et al., 2011; Oelke et al., 2013). Although most of the patients have a good clinical response, others require additional treatments. Among those are the use of **5-α-reductase** inhibitors and antagonists of other receptors, which could be involved in the pathogenesis of the disease and its symptoms, such as α_{1D}- adrenoceptors and **5-HT receptors** (McVary et al., 2011; Oelke et al., 2013). The development of drugs with selectivity for several of these receptors is in progress (see Chagas-Silva et al., 2014; Nascimento-Viana et al., 2016).

All three α_1-adrenoceptors are present in the human ureter, albeit the α_{1A}- and α_{1D}- adrenoceptors seem to be more abundant than the α_{1B}-subtype (Sigala et al., 2005). This forms the basis for one of the

several off-label uses of **prazosin** and other α_1-adrenoceptor antagonists in facilitating stone expulsion in urolithiasis through the relaxation of the ureter smooth muscle.

α_1- Adrenoceptors are expressed in both the bladder and urethra from different species and are described to be involved in dysfunctions of these organs (Alexandre et al., 2017; Michel & Vrydag, 2006). Phenylephrine contracts the bladder neck, indicating that the control of the tonus of this region involves activation of α_1-adrenoceptors (Michel & Vrydag, 2006). A recent study showed that male and female proximal urethra from mice and marmoset present striking differences in the presence of α_1-adrenoceptor subtypes, indicating that urinary retention might involve different mechanisms depending on gender (Alexandre et al., 2017). Although α_{1A}-adrenoceptors seem to be the main functional subtype in both genders, the contractions in response to phenylephrine are more vigorous in male, compared with those in female, urethra.

3.4 | α_1-Adrenoceptors in the genitourinary system: Epididymis, vas deferens, and seminal vesicle

From a biological and evolutionary perspective, α_1-adrenoceptors in the reproductive system are essential for male fertility and therefore for the existence of a species. Knocking out both α_{1A}- adrenoceptors and **P2X1** purinoceptors in male mice leads to complete infertility (White et al., 2013). During the emission phase of ejaculation, sympathetically released noradrenaline and **ATP** produce forceful contractions of the epididymis, vas deferens, seminal vesicles, urethra, and prostate, propelling the semen towards the urethral meatus. The complete infertility of the α_{1A}- P2X1 knockout mice results from the lack of contractility of these organs, as sperm collected from the epididymis still fertilizes ova in vitro. The key role for α_{1A}- adrenoceptors in reproduction is also demonstrated by the fact that the knockout of either α_{1B}- or α_{1D}-adrenoceptors has no effect on male fertility (Cavalli et al., 1997; Sanbe et al., 2007; Tanoue, Koshimizu, & Tsujimoto, 2002). On the other hand, knocking out only the α_{1A}-adrenoceptors reduces the fertility rate by 50%, whereas the triple α_1-adrenoceptor knockout male mice are infertile (Sanbe et al., 2007).

Transcripts encoding all three α_1-adrenoceptors have been found in organs of the male reproductive tract from rodents and humans, albeit in different proportions with relatively similar levels for α_{1A}- and α_{1D}- but lower levels for α_{1B}-adrenoceptors (Avellar, Lazari, & Porto, 2009; Burt, Chapple, & Marshall, 1995; Mendes, Hamamura, Queiroz, Porto, & Avellar, 2004; Pacini, Castilho, Hebeler-Barbosa, Pupo, & Kiguti, 2018; Pupo, 1998; Queiroz, Mendes, Porto, & Avellar, 2002; Silva, Megale, Avellar, & Porto, 1999; Yono et al., 2012). However, in isolated tissue preparations, the contractions of these organs in response to α_1-adrenoceptor agonists are often described as mediated by the α_{1A}-subtype (Avellar et al., 2009; Burt et al., 1995; Mendes et al., 2004; Pacini et al., 2018; Pupo, 1998; Silva et al., 1999; Yono et al., 2012). Importantly, the contractions of the mouse and rat vas deferens in response to electrical field stimulation have been described to involve α_{1D}- adrenoceptors, and at least in the mouse vas deferens, these receptors seem to play a role in contractions to exogenous noradrenaline (Bexis et al., 2008; Cleary, Slattery, Bexis, & Docherty, 2004; Mallard, Marshall, Sithers, & Spriggs, 1992). Therefore, it has been proposed that the α_{1A}- and α_{1D}- adrenoceptors are differentially located in relation to the sympathetic neuro-effector junction in the vas deferens, where the latter is more readily accessed by noradrenaline released from sympathetic nerve terminals than the former (Docherty, 2010).

3.5 | α_1- Adrenoceptors in the CNS

α_1- Adrenoceptors are the most abundant adrenoceptors in the CNS. However, knowledge on their localization and function has been hampered by the lack of subtype-selective antibodies, selective ligands with good brain barrier permeability, and the intrinsic complexity of brain functions. Despite these difficulties, significant knowledge has been gained with the use of genetically engineered mice (Koshimizu, Tanoue, & Tsujimoto, 2007; Perez & Doze, 2011; Tanoue et al., 2002, 2003; Zuscik et al., 2000). Studies with α_{1B}-adrenoceptor knockout mice showed the involvement of this subtype in memory consolidation and fear-motivated exploratory activity (Tanoue et al., 2002, 2003), whereas the overexpression of these receptors results in marked apoptotic neurodegeneration accompanied by locomotor impairment and seizures (Zuscik et al., 2000). Interestingly, the behavioural activation produced by **modafinil**, one of the most prescribed drugs for attention-deficit disorder and hyperactivity syndrome, is markedly attenuated in α_{1B}-adrenoceptor knockout mice, whereas in WT mice, this effect is blocked by **terazosin** (a non-selective α1-adrenoceptor antagonist) but not by **WB-4101** (selective α_{1A}-/α_{1D}-adrenoceptor antagonist) or **BMY-7378** (selective α_{1D}- adrenoceptor antagonist; Stone, Cotecchia, Lin, & Quartermain, 2002). These findings implicate the α_{1B}-adrenoceptors in the mechanism of action of modafinil. Changes in the seizure thresholds to chemoconvulsants have also been observed in mice expressing constitutively active α_{1A}- or α_{1B}-adrenoceptors (Perez & Doze, 2011). Alterations in cognitive functions have also been detected in α_{1A}- adrenoceptor knockout mice, whereas chronic stimulation of α_{1A}- adrenoceptors increases neurogenesis, enhances learning and memory, and improves the mood (reviewed in Perez & Doze, 2011). It has been suggested that the brain α_1-adrenergic system could be altered in depression (Stone, Lin, Rosengarten, Kramer, & Quartermain, 2003) and post-traumatic stress disorder (Roepke et al., 2017).

4 | REGULATION OF α_1-ADRENOCEPTORS BY PHOSPHORYLATION

Protein phosphorylation is among the major regulators of cell function. Initially discovered as a process that modulates glycogen metabolism, it later became clear that protein phosphorylation/dephosphorylation cycles regulate essentially all major life processes in cells, including overall metabolism, cell cycle, secretion and motility (see historical perspective in Cohen, 2002).

The α_1-adrenoceptors are phosphorylated, and this is a key regulatory process for these receptors (Cotecchia et al., 2004; Cotecchia, Scheer, Diviani, Fanelli, & De Benedetti, 1998; García-Sáinz et al., 2000; Vázquez-Prado, Casas-González, & García-Sáinz, 2003). The activation of PKC in rat hepatocytes blocked or desensitized α_1-adrenoceptor activity, suggesting that the receptor activity could be regulated by phosphorylation (Corvera & García-Sáinz, 1984). Receptor phosphorylation was later experimentally shown using DDT1-MF-2 cells, a hamster smooth muscle cell line (Leeb-Lundberg et al., 1985) that, like the rat hepatocytes, expresses the α_{1B} subtype. It is now known that α_{1B}-adrenoceptors are phosphorylated in response to α_1-adrenoceptor agonists and to a large variety of other agonists that act through different receptors, including GPCRs, **receptor tyrosine kinases**, **receptors with serine/threonine kinase activity** (**TGF-β**), and **intracellular receptors** (see Cotecchia et al., 1998; Cotecchia et al., 2004; García-Sáinz et al., 2000; García-Sáinz, Romero-Ávila, & Alcántara-Hernández, 2011; Vázquez-Prado et al., 2003). Evidence that the other α_1-adrenoceptors are also phosphorylated was subsequently reported (García-Sáinz, Rodríguez-Pérez, & Romero-Ávila, 2004; García-Sáinz, Vázquez-Cuevas, & Romero-Ávila, 2001; Vazquez-Prado, Medina, Romero-Avila, Gonzalez-Espinosa, & Garcia-Sainz, 2000).

Figure 3 illustrates the substrates for phosphorylation (serine/threonine residues; large red, yellow, and blue circles) in the intracellular domains of the three human α_1-adrenoceptor subtypes identified by mutagenesis and functional analysis (Diviani et al., 1996; Lattion, Diviani, & Cotecchia, 1994) or through MS and functional work (Alcantara-Hernandez et al., 2017; Alfonzo-Méndez, Carmona-Rosas, Hernández-Espinosa, Romero-Ávila, & García-Sáinz, 2018; Carmona-Rosas, Hernández-Espinosa, Alcántara-Hernández, Alfonzo-Méndez, & García-Sáinz, 2018).

The pioneer work of Diviani, Lattion, and Cotecchia (1997) and Lattion et al. (1994) showed that the key phosphorylation sites of the α_{1B}-adrenoceptor activated by adrenaline were located in the intracellular C-tail and correspond to five serines: three of them are substrates for GRKs and the remaining two for PKC (Figure 3).

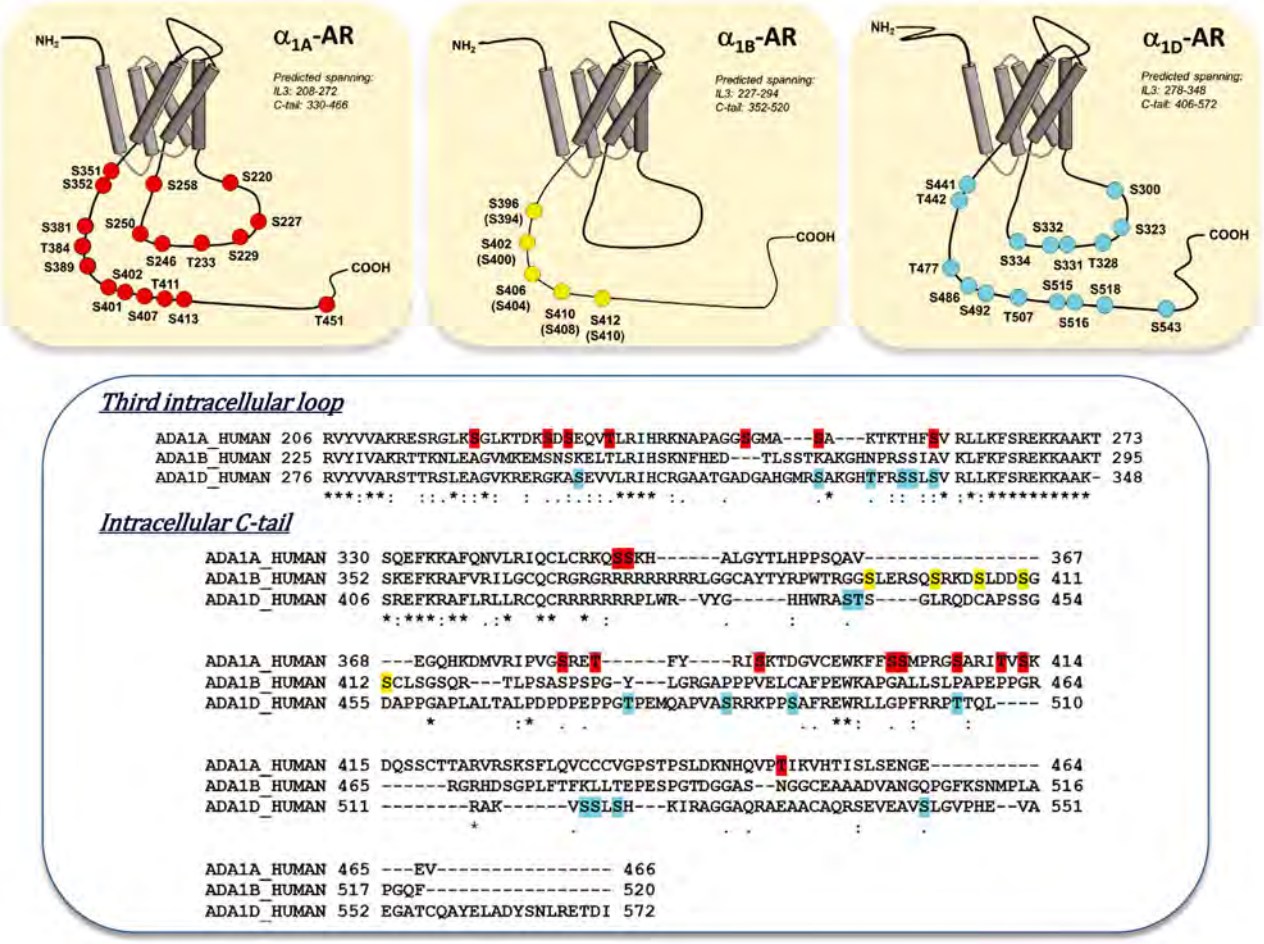

FIGURE 3 Schematic representation of the substrates for phosphorylation currently identified in the three human α_1-adrenoceptors (AR) subtypes (large red, yellow, and blue circles). Phosphorylated residues in the α_{1A}- and α_{1D}- adrenoceptors were identified by MS (Alcantara-Hernandez et al., 2017; Alfonzo-Méndez et al., 2018), whereas for the α_{1B}-adrenoceptor, the residues were identified by site-directed mutagenesis and functional analysis of the hamster orthologue (Diviani et al., 1997; in parenthesis are the sites defined for the hamster receptor). Below the diagram are the sequence alignments of the third intracellular loop and the carboxyl terminus (C-tail) of the three human α_1-adrenoceptor subtypes. Phosphorylated amino acids are marked in colour. Symbols: (a) "*" indicates single fully conserved residue; (b) ":" indicates conservative among subtypes; and (c) "." non-conservative among subtypes

However, truncation of the C-tail of the α_{1A}- (Price, Morris, Biswas, Smith, & Schwinn, 2002) and α_{1D}- adrenoceptor (Rodríguez-Pérez et al., 2009) rendered receptors that could be phosphorylated in response to agonists and PKC activation by phorbol esters, indicating the existence of phosphorylation sites in addition to those in the C-tail of these subtypes.

Considerable evidence indicates that the bulk and charge changes induced by receptor phosphorylation are not enough to explain the outcomes in signalling and cellular location. Therefore, it was hypothesized that the phosphorylation of specific residues results in a "barcode" pattern that in turn determines a receptor's fate (reviewed in Tobin, 2008; Tobin, Butcher, & Kong, 2008; see also Butcher et al., 2011). It has been proposed that the residues that are phosphorylated in a given receptor may change according to the cell type in which it is expressed, the type of stimulus to which such cells are subjected, and most importantly, the long-term response observed (Tobin, 2008; Tobin et al., 2008). This has markedly increased the interest in defining the phosphorylated sites and their functional importance. Considerable effort has been made during recent years to define this for a variety of receptors, mainly using partial affinity purification and MS (see some recent examples: Alfonzo-Méndez, Alcántara-Hernández, & García-Sáinz, 2017; Alvarez-Curto et al., 2016; Bouzo-Lorenzo et al., 2016; Bradley et al., 2016; Butcher et al., 2011; Butcher et al., 2014; Prihandoko et al., 2016; Zindel et al., 2016).

The phosphorylation sites of α_{1A}- and α_{1D}-adrenoceptors were only recently identifed (Alcantara-Hernandez et al., 2017;Alfonzo-Méndez et al., 2018;Carmona-Rosas et al., 2018). These adrenoceptors are phosphorylated in both the third intracellular loop and C-tail. Figure 3 illustrates the residues phosphorylated under baseline conditions and after stimulation by agonists or phorbol ester. The large number of phosphorylated residues (18 in α_{1A}- and 16 in α_{1D}-subtypes) and their distribution impose a considerable challenge to define their biological significance. For α_{1A}- adrenoceptors, there were differences in the phosphorylation patterns induced by noradrenaline and oxymetazoline (Alcantara-Hernandez et al., 2017). Not surprisingly, in silico analysis indicated the possible roles for GRK and PKC isoforms, but other kinases may also be involved (Alcantara-Hernandez et al., 2017; Alfonzo-Méndez et al., 2018). It is interesting that the phosphorylation sites detected for the α_1-adrenoceptor subtypes are not conserved among them and in only a few cases are the sites are conserved between two subtypes (α_{1A} S250/α_{1D} S323; α_{1A} S258/α_{1D} S334; α_{1A} S407/α_{1D} T507; see Figure 3).

In recombinant systems, α_{1D}- adrenoceptors are mainly misfolded or unable to undergo proper ligand binding and intracellularly located due to a motif present within the first N-terminal 79 amino acids of the receptor (Hague, Chen, et al., 2004; Hague, Uberti, et al., 2004; Pupo, Uberti, & Minneman, 2003). Recent evidence has indicated that N-terminal proteolysis of the α_{1D}- adrenoceptors could be an endogenous mechanism for proper plasma membrane expression (Kountz et al., 2016). To increase membrane expression of this receptor, we used N-terminally truncated receptors with additional mutations in the third intracellular loop and C-tail to gain insights on the phosphorylated residues. Among the major findings are the following: noradrenaline increased the intracellular calcium in cells expressing C-tail truncated α_{1D}- adrenoceptors to a similar extent as that seen in cells expressing these receptors with an intact C-tail (Alfonzo-Méndez et al., 2016; Alfonzo-Méndez et al., 2018). In contrast, α_{1D}- adrenoceptors in which the phosphorylated residues in the third intracellular loop were replaced by non-phosphorylatable amino acids presented a markedly decreased calcium response to noradrenaline (Alfonzo-Méndez et al., 2018). The data indicated that the third loop is important for signalling through G-protein coupling, as proposed for many GPCRs, and raises the possibility that phosphorylation of these residues might be important for receptor G-protein activation. The possibility that the C-tail could also participate in calcium signalling was not discarded, because in cells expressing C-tail-truncated α_{1D}- adrenoceptors with the third intracellular loop mutated, the calcium response to noradrenaline was decreased even further (Alfonzo-Méndez et al., 2018; Carmona-Rosas et al., 2018). ERK 1/2 phosphorylation in cells expressing these mutants was also studied. In cells expressing the control receptor, noradrenaline induced a rapid ERK 1/2 phosphorylation that decreased at 30 and 60 min, whereas in cells with the different mutants, the response was also rapid but either decreased much more slowly or remained elevated during the entire 60 min (Alfonzo-Méndez et al., 2018; Carmona-Rosas et al., 2018). This indicates that some of the phosphorylated residues, in both the third intracellular loop and C-tail, might participate in turning off the signal in the MAPK pathway (Alfonzo-Méndez et al., 2018; Carmona-Rosas et al., 2018).

An important additional finding was that although C-tail-truncated α_{1D}- adrenoceptors were able to mobilize calcium in response to noradrenaline, they were mainly detected in intracellular vesicles, and only a minor fraction was detected at the plasma membrane (Alfonzo-Méndez et al., 2016; Alfonzo-Méndez et al., 2018; Carmona-Rosas et al., 2018). The mutation of a motif in the C-tail of the α_{1D}- adrenoceptors which interacts with the post synaptic density protein (PSD95)/drosophila disc large tumour suppressor/zonula occludens-1 protein domain of syntrophins markedly decreased these receptorsat the plasma membrane (Chen, Hague, Hall, & Minneman, 2006). Furthermore, it has been observed that the knockout of syntrophins results in the loss of α_{1D}-adrenoceptor function in mouse aortic smooth muscle cells and the block of α_{1D}- adrenoceptor-mediated increases in BP in mice (Lyssand et al., 2008). These data support a role for the C-tail of the α_{1D}- adrenoceptors, not only in post-transcriptional regulation by phosphorylation but also in proper receptor insertion in the membrane.

5 | ASSOCIATION OF α_1-ADRENOCEPTORS WITH RAB PROTEINS

GPCRs are synthesized and properly folded in the rough endoplasmic reticulum, from where they reach the plasma membrane via intracellular traffic (anterograde transport). GPCRs are transported to the intracellular compartment (retrograde transport) and recycled back to the plasma membrane through constitutive and signal-triggered internalization and externalization processes. These latter events can take

place several times until the GPCRs are degraded in the lysosome or proteasome. Therefore, interaction with proteins that govern traffic is critical, and the signatures that define receptors' destinations are far from completely known. **Rab proteins** are among the master modulators of vesicular traffic. These comprise a large family of more than 60 monomeric GTPases that favour docking, fusion, cargo exchange, and vesicle transport along the cytoskeleton through interactions with the cytoplasmic face of vesicles with the aid of molecular motors (Hutagalung & Novick, 2011; Schwartz, Cao, Pylypenko, Rak, & Wandinger-Ness, 2007; Stenmark, 2009; Zerial & McBride, 2001).

Anterograde GPCR traffic has been studied by several groups, particularly that of Wang, Wei, and Wu (2018) and Wang and Wu (2012). Rab1, 2, and 6 modulate GPCR transit from the endoplasmic reticulum to the Golgi, whereas Rab8 and some ARF GTPases regulate the transfer to the plasma membrane (Wang et al., 2018; Wang & Wu, 2012). The anterograde traffic of α_1-adrenoceptors has also been studied, and it has been observed that the attenuation of Rab1 function inhibits the transit of α_{1A}- and α_{1B}-adrenoceptors to the plasma membrane, whereas augmented Raf1 function increases transit (Filipeanu, Zhou, Fugetta, & Wu, 2006; Wang & Wu, 2012). In addition, the overexpression of Rab1 selectively enhances ERK 1/2 activation and leads to cardiomyocyte hypertrophy in response to phenylephrine (Filipeanu et al., 2006).

To the best of our knowledge, the role of Rab proteins in the retrograde transport of α_{1B}-adrenoceptors was only recently reported. Agonist-activated α_{1B}-adrenoceptors (associated with homologous desensitization) mainly interacted with proteins present in early endosomes, such as early endosome antigen 1, Rab5, Rab4, and Rab11, but not with the late endosome markers Rab9 and Rab7 (Alfonzo-Méndez et al., 2017; Castillo-Badillo et al., 2015). In contrast, the activation of other receptors (such as sphingosine 1-phosphate receptors) or direct activation of PKC by phorbol esters (heterologous desensitization) induced a brief α_{1B}-adrenoceptor–Rab5 interaction, a more pronounced and sustained one with Rab9, and some interaction with Rab7 (Alfonzo-Méndez, Hernández-Espinosa, et al., 2017; Castillo-Badillo et al., 2015). It is worth mentioning that the action of **sphingosine-1-phosphate** on the phosphorylation/desensitization/internalization of α_{1B}-adrenoceptors mainly depended on the activation of PKC (Alfonzo-Méndez, Hernández-Espinosa, et al., 2017). These data suggested that agonist-activated α_{1B}-adrenoceptors undergo rapid internalization and recycling back to the plasma membrane, whereas heterologous desensitization was associated with a slower recycling pathway. However, preliminary work with non-adrenergic receptors indicates that although some similarities might exist with internalization and Rab protein association to other GPCRs, the findings with the α_{1B}-adrenoceptors cannot be generalized; in fact, different Rab protein association was observed using different agonists for the same receptor (García-Sáinz et al., 2016 unpublished observations). A major question arises from these observations regarding the nature of the "signal" or "tag" that defines the immediate destiny of a given receptor, that is, is the receptor interaction with a given Rab protein defined by conformational changes induced by the distinct ligands, by covalent (receptor phosphorylation, palmitoylation, or other) or non-covalent modifications, or by all of these? Our current hypothesis is that the so-called phosphorylation "barcode" (Tobin, 2008; Tobin et al., 2008) could be a major participant.

6 | DESENSITIZATION AND INTERNALIZATION OF α_1-ADRENOCEPTORS

Receptor desensitization, a decreased cell responsiveness to agonists, has been operationally divided into homologous and heterologous types. In homologous desensitization, the decreased responsiveness results from the previous activation of the same receptor affected, whereas in heterologous desensitization, the decreased responsiveness is not limited to the previously activated receptor type and may result from the activation of protein kinases and other molecular entities. The present review emphasizes the mechanisms involved in the homologous desensitization of α_1-adrenoceptors.

The interaction of α_1-adrenoceptors with proteins such as β-arrrestins and other molecular entities during these processes has been reported, and readers are directed to those publications (Cotecchia, Stanasila, & Diviani, 2012; Perez-Aso et al., 2013; Segura et al., 2013; Stanasila, Abuin, Dey, & Cotecchia, 2008).

There are significant differences in the degrees of desensitization and in the kinetics of internalization among the α_1-adrenoceptors. Studies comparing the internalization of these receptors in the same cellular background have shown that α_{1B}- and α_{1D}- adrenoceptors activated by noradrenaline, adrenaline, or phenylephrine internalize at a much faster rate than the α_{1A}- adrenoceptors (Cabrera-Wrooman, Romero-Avila, & Garcia-Sainz, 2010; Chalothorn et al., 2002; Stanasila et al., 2008; Wang et al., 2007). Conversely, the α_{1A}- adrenoceptors were much more resistant to desensitization induced by noradrenaline or phorbol ester than were the α_{1B}- and α_{1D}- adrenoceptors (Cabrera-Wrooman et al., 2010; Vazquez-Prado et al., 2000; Vazquez-Prado & Garcia-Sainz, 1996). Therefore, the general view is that the α_{1A}- adrenoceptors are less tightly regulated than the other two subtypes (Cotecchia, 2010).

More recent studies have shown that the α_{1A}- adrenoceptors can indeed undergo fast desensitization and internalization, but this depends on the agonist activating the receptor. In HEK293 cells, α_{1A}-adrenoceptors activated by oxymetazoline internalized at a much faster rate (~5 min) than when activated by noradrenaline (>45 min; Akinaga et al., 2013). Moreover, there was significant tachyphylaxis in the contractions of smooth muscles in response to oxymetazoline, whereas no tachyphylaxis was observed for noradrenaline. In addition, short exposures of cells or tissues to oxymetazoline (5 min) reduced the potency of noradrenaline in a subsequent exposure (Akinaga et al., 2013; Alcantara-Hernandez et al., 2017). The phosphorylation and faster desensitization/internalization of the α_{1A}- adrenoceptors activated by oxymetazoline largely depended on GRK2, whereas the phosphorylation and slower desensitization/internalization produced by noradrenaline depended on PKCα. In LNCap cells, the co-localization and co-immunoprecipitation of α_{1A}- adrenoceptors and β-arrestin produced by oxymetazoline was as strong as those produced by noradrenaline, despite the weak partial agonism of oxymetazoline for Ca^{2+} mobilization (Alcantara-Hernandez et al., 2017). Strikingly, oxymetazoline was more efficacious and potent than noradrenaline

for the phosphorylation of ERK 1/2 in LNCap cells but differed from what was observed in HEK293 cells (da Silva Junior et al., 2017). The superagonism of oxymetazoline for the ERK pathway in LNCap cells was unrelated to 5-HT receptor activation and was antagonized by prazosin (Alcantara-Hernandez et al., 2017). One of the most accentuated manifestations of biased agonism is the reversal in the order of potencies and/or efficacies for agonists in the production of different effects mediated by a receptor (Kenakin & Christopoulos, 2013; Pupo et al., 2016). This is a clear example of efficacy reversal and therefore of the biased agonism for oxymetazoline towards the ERK pathway versus Ca^{2+} mobilization at the α_{1A}- adrenoceptors.

Analysis of the phosphorylated α_{1A}- adrenoceptors activated by oxymetazoline and noradrenaline in LNCap cells revealed that two residues located in the C-tail (S381 and T384; see Figure 3) were exclusively phosphorylated when the receptor was activated by oxymetazoline, implicating this region in the differential effects of these two agonists (Alcantara-Hernandez et al., 2017). On the other hand, there were residues that were exclusively phosphorylated when the α_{1A}- adrenoceptors were activated by noradrenaline (S220 and S229), and these are in the beginning of the third intracellular loop. Therefore, depending on the agonist, clearly distinct phosphorylation barcodes are formed in these adrenoceptors.

The understanding of the phosphorylation barcoding produced by different ligands and their functional repercussions may provide the rationale for the development of α_1-adrenoceptor ligands more suited to some needed therapeutic purposes, such as less tachyphylactic ligands for more sustained rises in BP for the treatment of shock or vasoconstrictors without rebound effects.

7 | CONCLUDING REMARKS

In these nearly 45 years since the pharmacological separation of α_1-adrenoceptors from the α_2-adrenoceptors (Dubocovich & Langer, 1974; Langer, 1974; Starke, Montel, Gayk, & Merker, 1974) and 30 years after the cloning of the first α_1-adrenoceptor (the hamster α_{1B}-adrenoceptor; Cotecchia et al., 1988; for a historical perspective, see Langer, 1999), considerable progress has been made towards the understanding of the physiological roles of the α_1-adrenoceptor subtypes and their recognition as well as regulation by drugs. This knowledge translated into a few drugs that are safe and efficacious; the most relevant of them in our opinion being the so-called α-blockers for BPH and other micturition dysfunctions, which benefit a large proportion of the human population at some point in their lives.

The array of functions controlled by α_1-adrenoceptors has not been completely covered in this review, but enough has been presented to demonstrate the immense potential of these subtypes for innovative pharmacological interventions. The discoveries during the past two decades showing that drugs do not fit into simple agonist or antagonist categories and that receptors can regulate multiple signalling pathways further encourage the search for new drugs that target the α_1-adrenoceptor subtypes for new therapeutic purposes. For the success of this endeavour, continuous effort and sharp pharmacological reasoning are essential.

7.1 | Nomenclature of targets and ligands

Key protein targets and ligands in this article are hyperlinked to corresponding entries in http://www.guidetopharmacology.org, the common portal for data from the IUPHAR/BPS Guide to PHARMACOLOGY (Harding et al., 2018), and are permanently archived in the Concise Guide to PHARMACOLOGY 2017/18 (Alexander, S. P. H., Christopoulos et al., 2017; Alexander, Cidlowski et al., 2017; Alexander, Fabbro et al., 2017; Alexander, Peters et al., 2017).

ACKNOWLEDGEMENTS

Research in JAG's laboratory is supported by Grants from Consejo Nacional de Ciencia y Tecnología (CONACYT) [Grant 253156 and FDC-882] and Dirección General de Personal Académico-UNAM [PAPIIT, Grant IN200915]. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil (CAPES) – 23038.007773/2014-07, as J.A. received a CAPES Drug Discovery fellowship and during the preparation of this review was at the University of Nottingham, UK. Research in ASP's laboratory is supported by Grants from Fundação de Amparo à Pesquisa do Estado de São Paulo – FAPESP [2008/50423-7 and 2017/15175-1]. The authors are thankful to Dr. Vanessa Lima for kindly providing Figure 1.

Abstract—Intrathecal (i.t.) administration of quinpirole, a dopamine (DA) D2-like receptor agonist, produces antinociception to mechanonociceptive stimuli but not to thermonociceptive stimuli. To determine a cellular mechanism for the specific antinociceptive effect of D2-like receptor activation on mechanonociception, we evaluated the effect of quinpirole on voltage-gated Ca^{2+} influx in cultured dorsal root ganglion (DRG) neurons and the D2 DA receptor distribution in subpopulations of rat nociceptive DRG neurons. Small-diameter DRG neurons were classified into IB_4+ (nonpeptidergic) and IB_4- (peptidergic). Intracellular [Ca^{2+}] microfluorometry and voltage-clamp experiments showed that quinpirole reduced Ca^{2+} influx and inhibited the high voltage-activated Ca^{2+} current (HVA-I_{Ca}) in half of IB_4+ neurons, leaving Ca^{2+} entry and HVA-I_{Ca} in IB_4- neurons nearly unaffected. Pretreatment with ω-conotoxin MVIIA prevented the effect of quinpirole on HVA-I_{Ca} from IB_4+ neurons, indicating that quinpirole mainly inhibits $Ca_V2.2$ channels. Immunofluorescence experiments showed that D2 DA receptor was present mainly in IB_4+ small DRG neurons. Finally, in behavioral experiments in rats, the clinically approved D2-like receptor agonist pramipexole produced spinal antinociception in a similar fashion to quinpirole, with a significant effect only in the mechanonociceptive test. Our results explain, at least in part, why D2-like receptor agonists produce antinociception on mechanonociceptors. **© 2019 IBRO. Published by Elsevier Ltd. All rights reserved.**

Key words: dopamine, D2-like receptors, mechanonociception, $Ca_V2.2$ channels, neurotransmitter release, antinociception.

INTRODUCTION

The use of dopamine (DA) receptor agonists has been a useful treatment for a diversity of experimental and clinical pain conditions (Dickey and Minton, 1972; Kernbaum and Hauchecorne, 1981; Coffeen et al., 2008; Pellicer et al., 2010; Cobacho et al., 2014; Almanza et al., 2015). Some efforts have been made to determine the cellular and molecular mechanisms by which DA agonists produce their antinociceptive effect (Fleetwood-Walker et al., 1988; Tamae et al., 2005; Charbit et al., 2009; Taniguchi et al., 2011; Galbavy et al., 2013; Lu et al., 2018), but it is still incompletely understood. At the dorsal horn spinal cord level (lamina I and lamina II), it has been suggested that presynaptic and postsynaptic effects are responsible for the antinociceptive effect of DA and are mediated mainly by D2-like receptors (Tamae et al., 2005; Taniguchi et al., 2011; Lu et al., 2018).

In rodents, increasing evidence has demonstrated that *in vivo* DRG neurons respond specifically to one type of nociceptive stimulus (heat, cold, mechanical, *etc.*) (Cavanaugh et al., 2009; Le Pichon and Chesler,

2014; Emery et al., 2016). This specific response also occurs with different modulatory neurotransmitters. For example, intrathecal (i.t.) administration of a specific delta-opioid receptor (DOR) agonist produces antinociception only against mechanical nociceptive stimuli (Scherrer et al., 2009). DOR is expressed only in mechanonociceptive DRG neurons, which explains the modality-specific antinociception induced by DOR activation.

A similar effect is observed with the administration of quinpirole, a D2-like DA receptor agonist. Quinpirole i.t. administration at low doses (1.8 nmol) produces mechanical antinociception, leaving unaffected the peripheral processing of thermonociceptive stimuli (Almanza et al., 2015). The mechanical antinociceptive effect is completely abolished by i.t administration of D2-like receptor antagonists, suggesting that the antinociceptive effect is due to the activation of D2, D3 and D4 DA receptors, which are expressed in primary sensory neurons and the spinal cord (Xie et al., 1998; Zhu et al., 2007; Kawamoto et al., 2012).

To extend our understanding of the cellular and molecular mechanisms by which D2-like receptor agonists exert their effect only on mechanonociceptive pathways, we evaluated 1) the effect of quinpirole on voltage-gated Ca^{2+} channels (VGCC) and on the electrical properties of small IB_4+ and IB_4- DRG neurons, 2) determined the D2 receptor expression by Western blot and their expression pattern by immunohistochemistry in lumbar DRG, and 3) assessed the behavioral response to the clinically relevant D2-like receptor agonist pramipexole in nociceptive tests in rats.

EXPERIMENTAL PROCEDURES

The present work was conducted following the recommendations of the *Guide for the Care and Use of Laboratory Animals* of the National Academy of Sciences (USA), the International Association for the Study of Pain (IASP) (Zimmermann, 1983), and the local regulations for the use and care of laboratory animals (NOM-062-ZOO-1999). All the protocols in this work were approved by the *Comité de Ética en Investigación* from *Instituto Nacional de Psiquiatría Ramón de la Fuente Muñiz*. The work adhered to the ARRIVE guidelines for studies reporting the results from *in vivo* animal experiments (Kilkenny et al., 2010).

Animals

Wistar rats used for this work were produced and maintained in our institutional animal care facilities. The animals were kept in acrylic cages (sawdust bedding) with *ad libitum* access to food (rat chow) and water. Room temperature was set to 22 °C, with dark/light cycles of 12 h. For neuronal cell-culture and Western blot experiments, animals from P21 to P25 were used (either sex), and for immunohistochemistry and behavioral tests, male rats weighing 250–350 g were used.

DRG neuron isolation and culture

For cell culture, the rats were anesthetized with isoflurane (Sofloran Vet, PISA, México) and then decapitated. Under a stereomicroscope, DRGs were isolated from the L4 to the L6 level and immersed in ice-chilled Dulbecco's Modified Eagle Medium (DMEM; Gibco, Life Technologies, Rockville MD, USA). Isolated ganglia were incubated for 30 min in DMEM containing trypsin (1 mg/mL; Affimetrix-ThermoFisher, Waltham, MA, USA), and collagenase type IA (1 mg/mL; Sigma-Aldrich, St Louis MO, USA) at 37 °C. Then, ganglia were washed and triturated with a fire-polished Pasteur pipette. The cell suspension was centrifuged (5 min, 5000 rpm), and the medium was replaced with fresh, sterile DMEM. After three washouts, isolated DRG neurons were plated on glass coverslips (Corning, New York, NY, USA) pretreated with poly-L-lysine (0.01%; Sigma Aldrich), which were placed onto 35-mm culture dishes (Trueline, USA) containing DMEM supplemented with N2 (Gibco, Life Technologies) and penicillin–streptomycin-amphotericin B (100 U/mL, 0.1 mg/mL, 0.25 μg/mL; respectively; Sigma-Aldrich). The neurons were maintained at 37 °C (NuAire Inc., Plymouth, MN, USA) in a 10% CO_2 atmosphere until the recording (18–24 h).

Calcium imaging recordings

For these experiments, five rats were used. The DRG neurons were incubated with Fluo-4 AM (1 μM; Molecular Probes, Life Technologies; 50 min at 37 °C), and placed in a recording chamber attached to the stage of a microscope (Nikon Eclipse 80i, Japan); the DRG neurons were perfused with extracellular solution (Table 1; 2 mL/min). Fluo-4 AM was excited at 488 nm and the emitted fluorescence was bandpassed at 510 nm. The images were acquired at 1 Hz frequency (20 ms exposure) with a CCD camera (Andor Technology iXon 897, Oxford Instruments, High Wycombe, UK) controlled by the software Andor iQ version 1.10.2, at room temperature (22–25 °C).

The increase of $[Ca^{2+}]_i$ was induced by local depolarization (3 s; 10 min between stimuli) with a high K^+ solution (60 mM; Table 1). As methodological control, a Ca^{2+}-free extracellular solution was used, and the increment in $[Ca^{2+}]_i$ elicited by high K^+ was prevented (data not shown). The fluorescence amplitude (ΔF) produced in control was compared with ΔF produced in the presence of an agonist or antagonist of the D2-like DA receptors or DAMGO, as well as after the washout of the drug. In both, calcium imaging and patch-clamp experiments, when the recording finished, the neurons were incubated for 10 min with the IB_4 Alexa-fluor 488 conjugate (10 μg/mL; Life Technologies-ThermoFisher, Waltham, MA, USA), rinsed for 5 min and observed to determine their binding to IB_4.

Images files were converted to TIFF and imported into FIJI for *post hoc* analysis (Schindelin et al., 2012). Basal fluorescence was obtained from areas of the cell displaying the most uniform and least intense fluorescence (F_0). The amplitude of the rise of $[Ca^{2+}]_i$ was expressed as ΔF arbitrary units (a.u.), where ΔF represents the difference

between instantaneous Ca^{2+} fluorescence less the basal Ca^{2+} fluorescence (F_0). Analysis of the area under the curve (AUC) of the ΔF transient was performed with Origin 2016 software (OriginLab Corp., Northampton, MA, USA). We assessed the first 25 s of the trace, which represents the Ca^{2+} influx from bath solution during high K^{+}-induced depolarization. Although mechanonociceptive neurons belong to both A-delta (medium-size neurons) and C-fibers (small-size neurons), we choose to only record small-size neurons to be sure that we were recording nociceptors, for this reason neurons with diameter $\leq$ 26 μm were considered for the analysis (Taddese et al., 1995; Stucky and Lewin, 1999; Blair and Bean, 2002).

Whole-cell patch-clamp recording

A total of 47 animals were used in these experiments. The coverslips containing DRG neurons were placed inside a recording chamber adapted to the mechanical stage of an inverted microscope (TS100) equipped with a mercury lamp and filters for fluorescence observation (Nikon Corporation, Tokyo, Japan). The recording chamber was bathed with external solution at a constant flow (0.5 mL/min) maintained with a peristaltic pump (Cole-Parmer, Vernon Hills IL, USA). The solutions used for the recordings are listed in Table 1.

Patch pipettes were pulled from Clark custom patch borosilicate glass (Harvard Apparatus, MA, USA) with a P-97 puller (Sutter Instruments, Palo Alto, CA, USA). Pipette resistances were 2–3 MΩ when filled with the internal solution (Table 1). To drug delivery, a perfusion system VC-6 couplet to a fast-step solution changer was used (SF-77B; Warner Instruments, Hamden, CT, USA).

Voltage-clamp and current-clamp recordings were obtained in whole-cell configuration at room temperature (21–22 °C). Acquisition and stimulation were performed using a PC-505B patch-clamp amplifier (Warner Instruments, Hamden, CT, USA), Digidata 1440 (Molecular Devices, Sunny Valley, CA, USA) and the software WinWCP (v. 4.7; John Dempster; University of Strathclyde, Glasgow, Scotland). Data were acquired at 20 kHz, and the low-pass filter was set at 5 kHz. Since C_m is an indirect measure of the cell size, neurons were classified as small when their C_m was 45 pF or less (Stucky and Lewin, 1999; Baccei and Kocsis, 2000).

In all cases, a control trace (average of 3 traces recorded) of action potential (AP) or voltage-clamp recording was compared with the trace after perfusion of the drug (average of 3 traces recorded). Then, the neuron was left to recovery from the drug effect, and the washout response was recorded.

The HVA-I_{Ca} was isolated and recorded in small-diameter DRG neurons with a CsCl-based intra and extracellular solutions (Table 1). HVA-I_{Ca} was elicited with a depolarizing pulse to −10 mV for 30 ms, from a holding potential (V_H) of −60 mV (25 s between voltage steps). Data are shown as an inhibition percentage with respect to the control condition.

For current-clamp experiments, internal and extracellular solutions were used (AP solutions, Table 1). APs were elicited with a square pulse of 164 ± 23 pA in IB_4+ and 106 ± 16 pA in IB_4- small DRG neurons (500 ms of duration) and a current ramp from 0 to 558 ± 37 pA in IB_4+ and from 0 to 446 ± 55 pA in IB_4- small DRG neurons (750 ms of duration). Current was injected to set the V_H close to −60 mV in every cell. The duration of the AP was measured at 50% of the peak amplitude from resting potential.

Immunofluorescence

Under anesthesia with sodium pentobarbital (63 mg/kg), rats were transcardially perfused with a clearing solution (0.9% NaCl + 5 IU/mL of heparin; 50–200 mL) followed by 350–400 mL of 4% paraformaldehyde in PBS 1x (Sigma Chemical Co., St. Louis, MO). Lumbar DRGs from 4 rats were removed and postfixed in the same fixative for 2 h at 4 °C. Then, they were cryoprotected in 30% sucrose and stored at 4 °C until their use. Ganglia were immersed in Tissue Freezing Medium (Leica Instruments, Nussloch, Germany). Subsequently, 14-μm-thick serial sections were cut in a cryostat

INFORME DE LABORES 2019

microtome (Microm HM 525, Microm International GmbH, Germany) and mounted on gelatin-coated slides. Double immunofluorescence protocol was done as previously reported (León-Olea et al., 2013). Briefly, after blocking to minimize nonspecific staining, random sections were incubated with rabbit D2 receptor antibody (Chemicon, cat. AB5084P, 1:300) and mouse Calcitonin-Gene Related Peptide (CGRP) antibody (Pierce, cat. MA1–20209, 1:300) in the same blocking solution for 48 h at 4 °C. After washing, tissue was incubated with Alexa Fluor 647 donkey anti-rabbit and Alexa Fluor 555 donkey anti-mouse secondary antibodies (Invitrogen Corp., Carlsbad, CA, USA) at 1:300 dilution in blocking solution, in a humidified chamber at 37 °C for 1.5 h. Afterward, the sections were incubated with IB_4 at 10 μg/mL for 10 min, washed (3 × 10 min) with PBS, and finally mounted onto glass slides with ProLong Diamond Antifade mounting medium with 4′,6-diamidino-2-phenylindole (DAPI; ProLong Antifade Kit, Molecular Probes; Eugene, ON, USA). In several random sections, the primary antibody was replaced by blocking solution, representing methodological control sections.

Sections were analyzed with a Plan-Apochromat 63x/1.40 oil DIC M27 objective (Carl Zeiss) in a Zeiss LSM 800 Airyscan laser scanning confocal microscope attached to an Axio Observer.Z1/7 microscope. All the pinholes were calibrated at 1 airy unit. Confocal images were converted to 8-bit TIFF format with a ZEN (blue edition, v2.3 Carl Zeiss microscopy GmbH, 2011).

Western blot

Lumbar DRGs (L3-L6) from 4 rats were collected for each experiment, and 3 experiments were carried out (n = 3), for a total of 12 rats used in these experiments. For striatum control blots (positive expression control), left or right striatum from three rat brains were used (n = 3). The protocol was the same as previously reported (Ortega-Legaspi et al., 2011), with mouse anti D1 receptor (Santa Cruz, Cat sc-33,660, 1:1000), rabbit anti D2 receptor (Chemicon, cat. AB5084P, 1:1200) and goat anti-actin (Santa Cruz, cat. sc-1616, 1:8000) in the blocking solution. After three washes, the membrane was incubated with secondary antibodies: HRP donkey anti-mouse (Santa. Cruz, cat. sc-2314, 1:2500), HRP donkey anti-rabbit (Jackson Immunoresearch, cat. 711–035-152, 1:5000) and HRP donkey anti-goat (Santa Cruz, cat. sc-2020, 1:10,000) in blocking solution for 2 h at room temperature. Bound antibody was visualized on films (Kodak, cat 604–0331) using an enhanced chemiluminescence kit (Perkin Elmer, Waltham, MA USA).

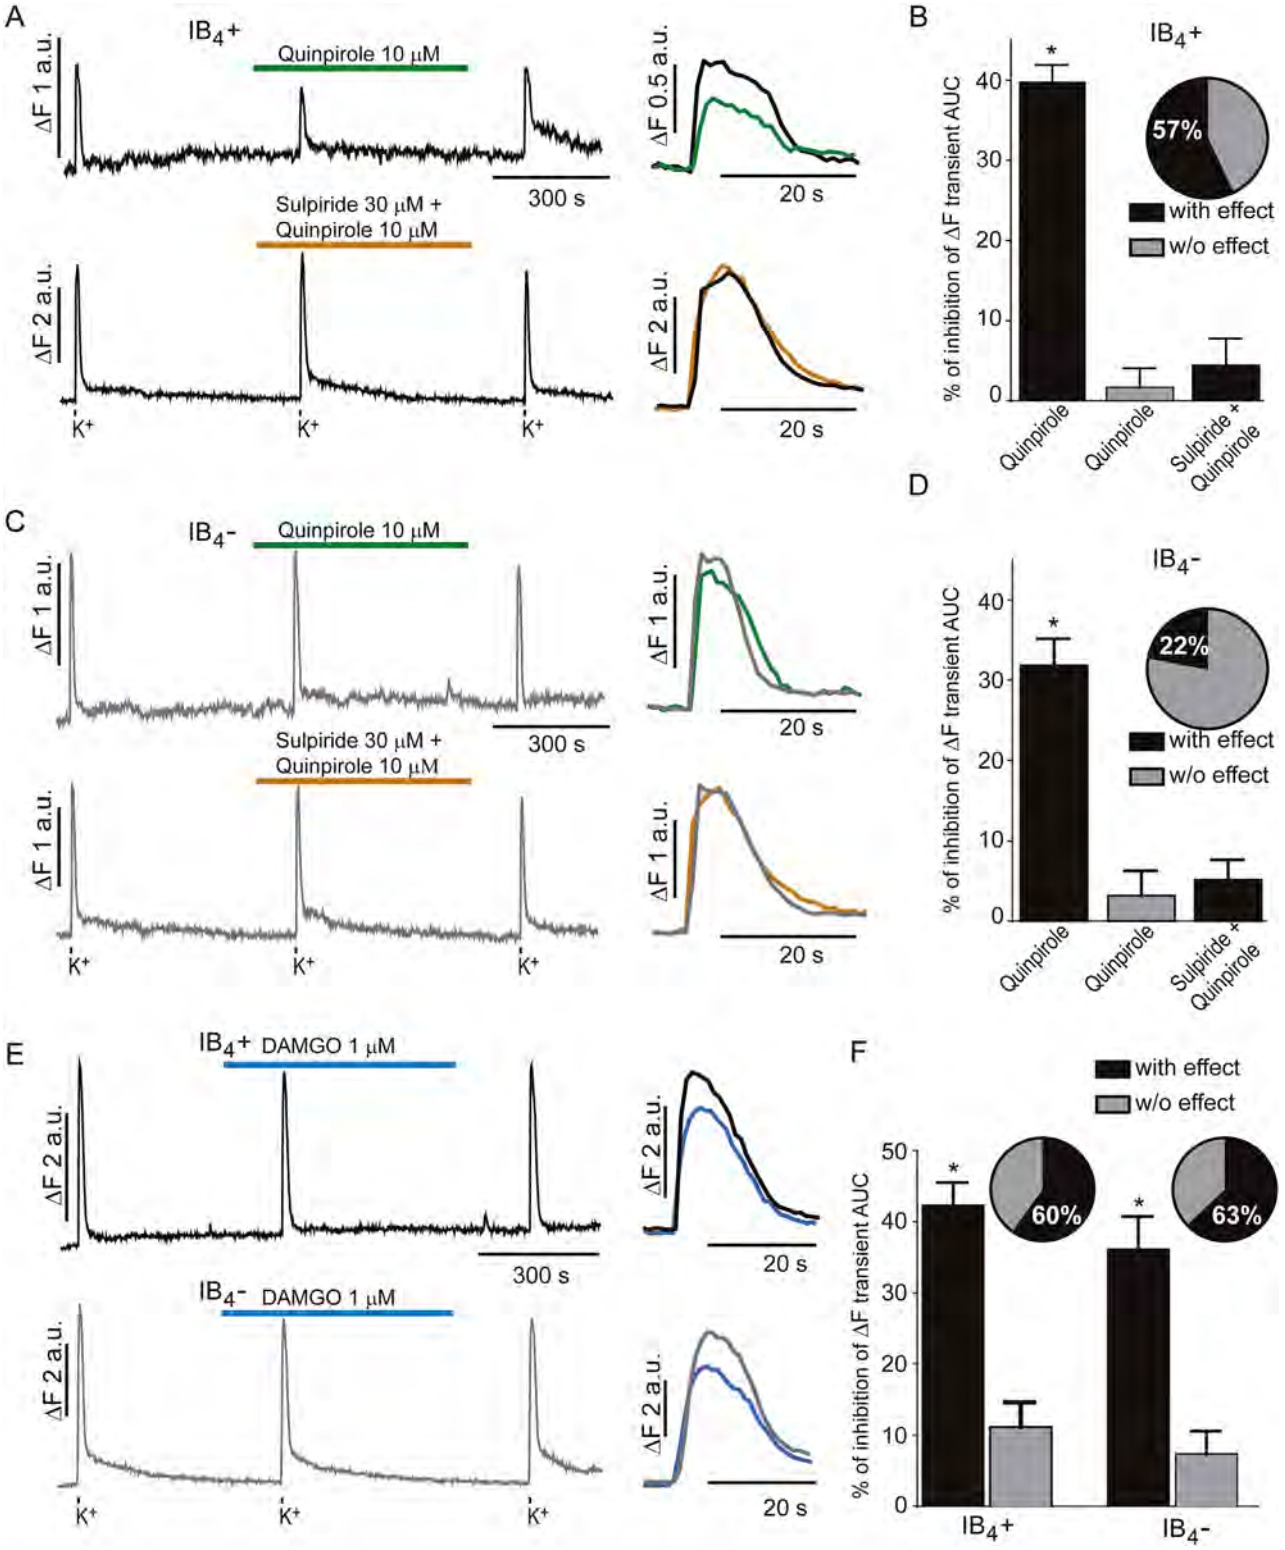
Nociceptive behavioral test

All experiments were carried out between 9 AM and 3 PM. A total of 35 animals were used in these experiments. All animals were caged individually in acrylic boxes and were habituated 2 days 30 min each, previous to behavioral tests. The animals were randomly assigned to one of the five experimental groups: control group (VH 50 μL), pramipexole at doses of 3, 10 or 30 nmol (D2-like agonist) and SKF-38393 30 nmol (D1-like agonist). Paw withdrawal latencies (PWL) were tested prior to the i.t. administration to determine the nociceptive threshold. Mechanical and thermonociceptive responses were measured 15, 30, 60 and 120 min after drug administration. Drug administration was done as previously described (Almanza et al., 2015). The method for the acute i.t. administration was chosen because it is of our interest to compare the effect of pramipexole with the effect of the quinpirole used in our previous works (Almanza et al., 2015; Mercado-Reyes et al., 2019). In brief, rats were anesthetized (isoflurane 2% + medical oxygen 98%; Pisa Vet., México) and a small incision (~3 mm) was made at L4-L6 level, a 25 G needle connected to a 50 μL Hamilton syringe was used to i.t. drug delivery, the deposit of the drug was made in ~3 s; after the injection, one shot of Xylocaine 10% was sprayed on the wound. The effect of the anesthetic disappeared within 5 min after the animal was left for recovery, then behavioral testing started 15 min after the drug administration. The experimenter was blinded for the formulation of the administered solution.

For mechanonociception, animals were tested in the dynamic plantar aesthesiometer (Ugo Basile, Varese, Italy). Briefly, a metallic filament pressed the mid-plantar surface of a hind limb with a ramp stimulus (from 0 to 50 g in a lapse of 10 s). The latency and the force used to produce the flexor reflex were recorded automatically. Four consecutive trials were averaged to determine the PWL. Cut-off time was 25 s to avoid tissue damage. For thermonociception, animals were tested in the Hargreaves apparatus (Plantar test; Ugo Basile, Varese, Italy). Animals were exposed to a heat source to hind paws, and the latency of the flexor reflex was automatically recorded. Cut-off time was 25 s to avoid tissue damage. Measurements from three consecutive trials were averaged to determine the hind PWL. All the animals were euthanized immediately after the experiments within a CO_2 chamber.

Drugs

± Quinpirole (D2-like receptor agonist), sulpiride (D2-like receptor antagonist), DAMGO ([D-Ala2, N-Me-Phe4, Gly5-ol]-enkephalin; mu-opioid receptor selective agonist), pramipexole (clinically approved D2-like receptor agonist), SKF-38393 (D1-like receptor agonist) and ω-conotoxin MVIIA (ω-CMVIIA; specific and irreversible $Ca_V2.2$ blocker (Feng et al., 2003)) were obtained from Sigma Aldrich (St. Louis, MO, USA). Stock solution of sulpiride was prepared in absolute ethanol, while the other drugs were dissolved in distilled water. The final concentration of ethanol administered i.t. was always $\leq$0.2%. For i.t. administration, the drugs at the desired concentrations were dissolved in sterile saline solution (NaCl 0.9%) and filtered through a 0.22 μm pore membrane. The vehicle (VH), consisting of sterile saline solution containing 0.1% absolute ethanol was used as a control. Drugs were dissolved in normal extracellular solution for current-clamp experiments and I_{Ca} extracellular solution for voltage-clamp experiments (Table 1).



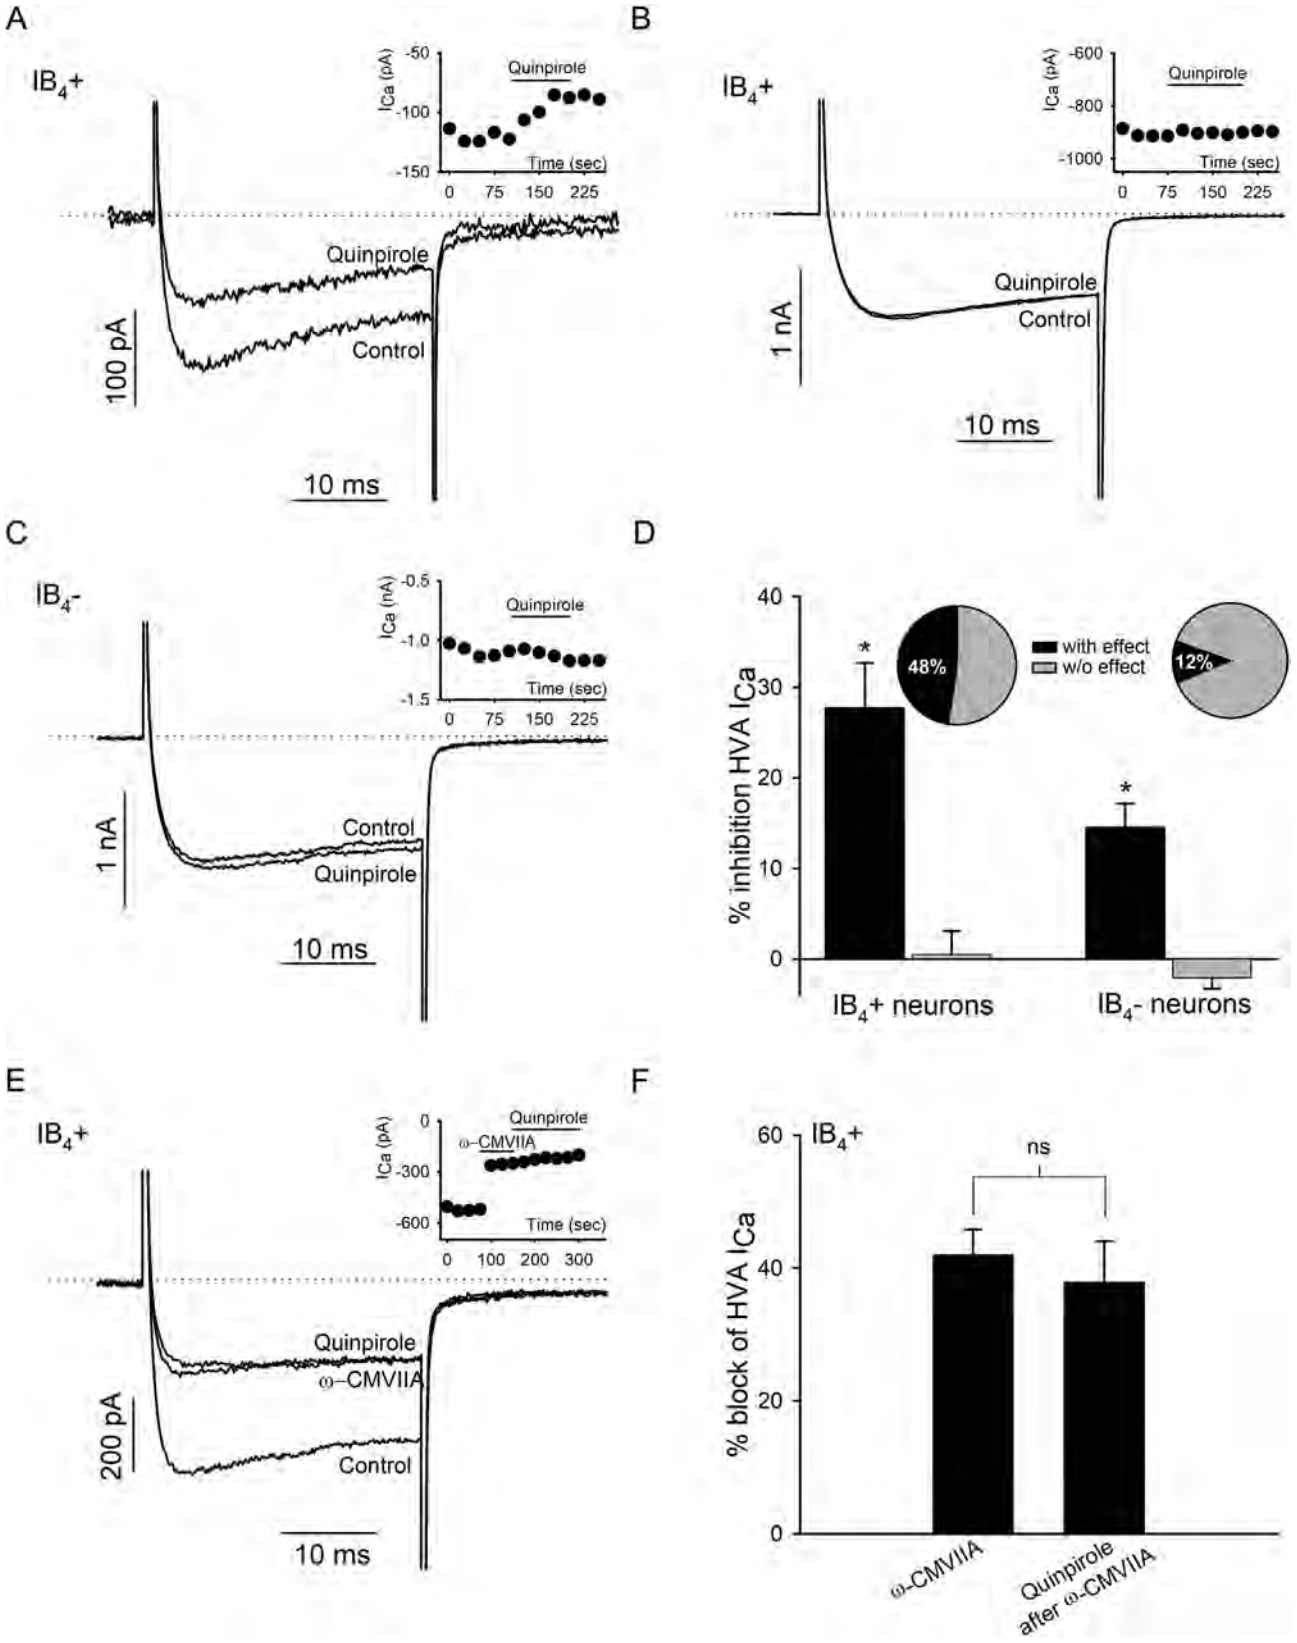


Fig. 1. *Quinpirole's effect on the intracellular Ca^{2+} transient in IB_4+ and IB_4- DRG neurons*. In A and C, representative traces of ΔF transient induced by high K^+ in control, in the presence of 10 μM quinpirole (top) with or without sulpiride 30 μM (bottom), in IB_4+ (A) and IB_4- (C) neurons; right panels show a magnification of superposed ΔF transient in control (black traces), during 10 μM quinpirole application (green traces) or with sulpiride (orange traces). In B and D, the percentage of inhibition of ΔF transient AUC induced by quinpirole in IB_4+ and IB_4- DRG neurons, respectively. In E, representative traces of ΔF transient induced by high K^+ in control, in the presence of 1 μM DAMGO in IB_4+ (top) or in IB_4- (bottom) neurons, right panels show a magnification of superposed ΔF transient in control (black traces) and during DAMGO perfusion (blue traces). In F, the percentage of inhibition of ΔF transient AUC induced by DAMGO in IB_4+ and IB_4- DRG neurons. The pie charts inserts show the percentage of affected (black) or unaffected (gray) neurons by quinpirole or DAMGO. Statistical differences were determined using one-way-ANOVA (denoted by *). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

INFORME DE LABORES 2019

Data analysis

All the data are presented as the mean ± standard error of the mean (S.E.M.). In patch-clamp and Ca^{2+} microfluorometry experiments, the *n* of each group represents the number of DRG neurons recorded. In immunofluorescence and behavioral experiments, the *n* of each group represents the number of animals studied. In Western blot, the *n* represents the number of

INFORME DE LABORES 2019

experiments. In each experiment, tissue was collected from various animals.

More than two standard deviations of the mean (more than 20%) obtained in control experiments (data not shown) was taken as significant effect induced by test solutions in Ca^{2+} microfluorometry.

In Western blot, the optical densities of the bands were quantified with ImageJ (NIH, USA). In behavioral tests, data were normalized to obtain the maximum drug effect and the AUC. When comparing proportions, statistical significance was assessed by the χ^2 test. Normal distribution and equal variance of data were verified before statistical tests. Comparisons between groups were done with ANOVA and Student's *t*-tests (when two groups were compared). Differences were considered significant when $P < .05$.

RESULTS

D2-like receptor activation effect on $[Ca^{2+}]_i$ in small DRG neurons

In 57% of small IB_4+ neurons (38 of 67), 10 μM quinpirole reduced the ΔF transient AUC induced by high K^+ depolarization by 40 ± 2% (n = 67; $P < .0001$, one-way ANOVA, $F_{10,148} = 38.1$) (Fig. 1A, B top, C). Meanwhile, quinpirole reduced the ΔF transient AUC by 32 ± 3% only in 22% of IB_4- small DRG neurons (5 of 22), a lower percentage of quinpirole sensitive neurons compared with IB_4+ neurons (χ^2 test, $P = .007$). The inhibitory effect of quinpirole was analogous in both IB_4+ and IB_4- small DRG neurons ($P = .92$, one-way ANOVA) (Fig. 1B, D). Sulpiride 30 μM prevented the effect of quinpirole in both IB_4+ and IB_4- nociceptive sensory neurons (Fig. 1A bottom, B; C bottom, D).

As positive control, we used DAMGO (1 μM), which produced a significant decrement in the ΔF transient AUC after high K^+ depolarization in both, IB_4+ (42 ± 3%; n = 12; $P < .0001$, one-way ANOVA, $F_{10,148} = 38.1$) and IB_4- neurons (36 ± 5; n = 10; $P < .0001$, one-way ANOVA; $F_{10,148} = 38.1$) (Fig. 1 E, F); in both populations, the effect of DAMGO on ΔF transient AUC was not different ($P = .97$, one-way ANOVA) (Fig. 1F), and the percentage of IB_4+ and IB_4- neurons that responded to DAMGO was similar (χ^2 test, $P = .9$) (Fig. 1F).

D2-like agonist effect on HVA I_{Ca} from small-diameter DRG neurons

HVA-I_{Ca} in small DRG neurons displayed little inactivation during 30 ms of the voltage pulse to −10 mV, with similar temporal courses in IB_4- and IB_4+ neurons (Fig. 2). In IB_4+ neurons, 10 μM quinpirole reduced the HVA-I_{Ca} amplitude by 27 ± 5% in 10 of 21 neurons (t(9) = −4.741, $P = .000529$, Student's *t* test; $C_m = 30$ ± 3 pF) (Fig. 2A, D), while in the remaining neurons, quinpirole produced no changes in the HVA-I_{Ca} amplitude (change percent 1 ± 3%; t(10) = −1.160, $P = .136$, paired Student's *t* test; $C_m = 31$ ± 7 pF) (Fig. 2B, D). In IB_4- neurons, quinpirole did not affect the HVA-I_{Ca} amplitude in 30 of 34 neurons, with a nonsignificant current amplitude increment of 2 ± 1% (t(29) = 0.0703, $P = .472$, paired Student's *t* test; $C_m = 37$ ± 4 pF) (Fig. 2C, D). In only 4 out of 34 neurons did quinpirole produce a significant inhibition of the HVA-I_{Ca}, whose reduction was 14 ± 3% (t(3) = −2.489, $P = .0443$, paired Student's *t* test; $C_m = 35$ ± 8 pF) (Fig. 2D). The percentage of HVA-I_{Ca} inhibition by quinpirole in IB_4+ neurons was not different respect to the observed in the four IB_4- neurons (t(12) = 1.585, $P = .139$, paired Student's *t* test), but, the proportion of neurons in which quinpirole inhibited the HVA-I_{Ca} was higher in IB_4+ compared to IB_4- neurons (χ^2 test, $P = .008$).

To evaluate if the quinpirole effect was on the N-type VGCC ($Ca_V2.2$), we tested in IB_4+ neurons the effect of the quinpirole after pretreating the neurons with a blocker of the N-type Ca^{2+} channel. Perfusion of 1 μM ω-CMVIIA by itself reduced the HVA-I_{Ca} in 42 ± 4% (n = 11; $C_m = 34$ ± 3 pF; $P < .001$, one-way ANOVA, $F_{2,\ 30} = 67.250$) (Fig. 2E, F). Following ω-CMVIIA pretreatment, 10 μM quinpirole was unable to induce its inhibitory effect: the percentage of blocked HVA-I_{Ca} remained similar to the ω-CMVIIA effect (38 ± 6%; n = 11; $P = .501$, one-way ANOVA $F_{2,\ 30} = 67.250$) (Fig. 2E, F), suggesting that quinpirole's main effect was on ω-CMVIIA-sensitive Ca^{2+} channels (Fig. 2F).

D2-like agonist effect on action potential firing of small-diameter DRG neurons

In the presence of 10 μM quinpirole, there was no significant change in the number of APs produced by a depolarizing square pulse (500 ms) in IB_4+ neurons (6 ± 0.7 APs in control, 5.9 ± 0.8 APs after quinpirole treatment; n = 16; $C_m = 26$ ± 2 pF; t(21) = 0.05, $P = .95$) (Fig. 3A, C). Similar results were obtained in IB_4- neurons (6.2 ± 0.5 APs in control, 6.2 ± 0.6 APs after quinpirole treatment; n = 22; $C_m = 20$ ± 2 pF; t(15) = 0.85, $P = .41$) (Fig. 3B, C). To unmask a possible quinpirole's effect, a ramp current pulse was used for stimulation. Quinpirole did not affect the AP discharge in IB_4+ neurons (9 ± 2 APs in control, 9 ± 2 APs after quinpirole; n = 6; $C_m = 26$ ± 2 pF; t(5) = 0.55, $P = .61$) (Fig. 3D, F), nor in IB_4- neurons (10

Fig. 2. *Quinpirole's effect on HVA-I_{Ca} in IB_4+ and IB_4- DRG neurons.* In A and B, traces of HVA-I_{Ca} ($V_H = -60$ mV, voltage step to −10 mV) recorded in IB_4+ DRG neurons before (control trace) and after 10 μM quinpirole perfusion. In C, traces of HVA-I_{Ca} recorded in IB_4- neurons before (control trace) and after 10 μM quinpirole perfusion. Inserts in A, B and C show the time course of quinpirole's effect on HVA-I_{Ca} amplitude. In D, the percentage of HVA-I_{Ca} inhibition by quinpirole in IB_4+ and IB_4- DRG neurons is showed, in which there was an effect (black bars) and those where did not (gray bars). The pie graph shows the percentage of DRG neurons where quinpirole inhibited (black) or not (gray) the HVA-I_{Ca} for each population. Statistically significant changes are denoted with * ($P < .05$, paired Student's t test). In E, representative traces of HVA-I_{Ca} recorded in IB_4+ DRG neurons in control conditions, after 1 μM ω-conotoxin MVIIA and posterior perfusion of 10 μM quinpirole. Time course of drug's effect on HVA-I_{Ca} amplitude is shown in the insert. In F, bar graphs show the percent of blockade of HVA-I_{Ca} by ω-conotoxin MVIIA and quinpirole in presence of N-type Ca^{2+} channel blocker. Differences were not significant ($P > .05$, paired Student's t test).

INFORME DE LABORES 2019

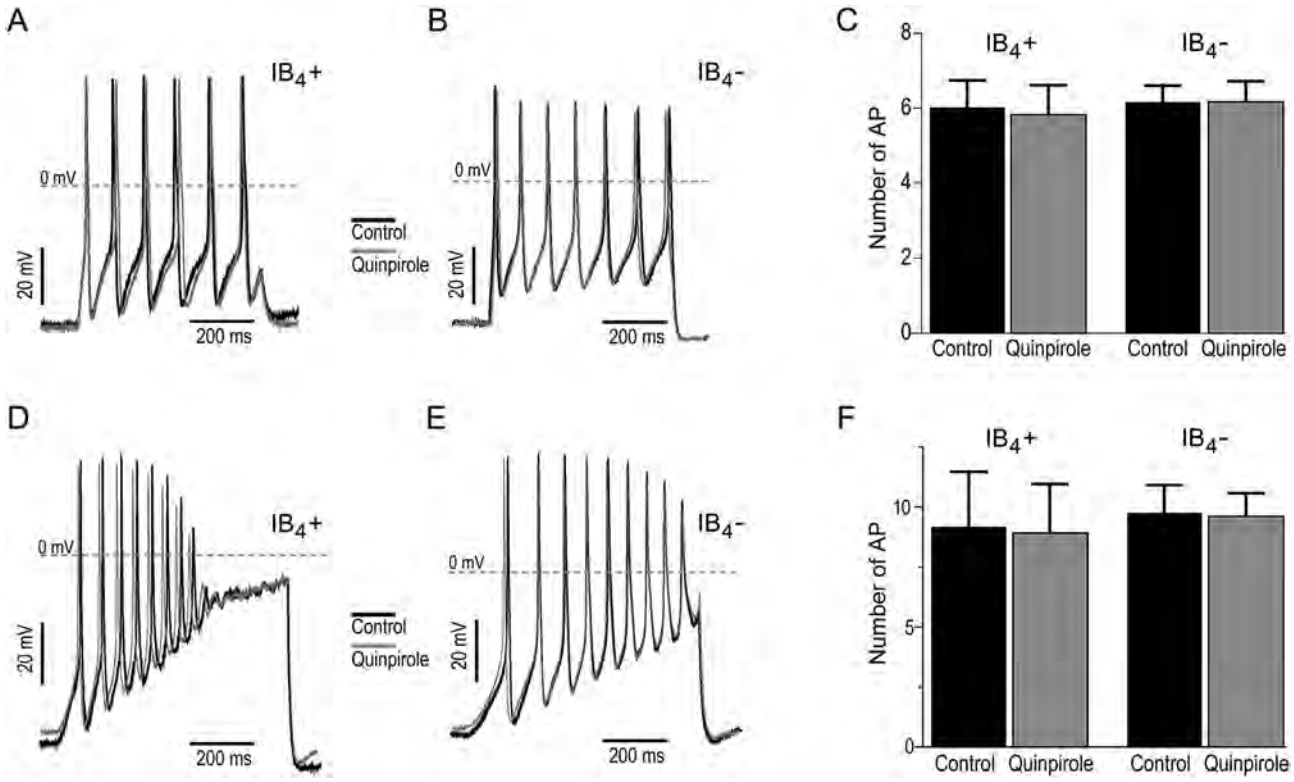

Fig. 3. *Effect of quinpirole on AP firing in small-diameter DRG neurons.* In A and B, representative AP firing obtained with a square pulse stimulation, recorded before (black traces) and after quinpirole perfusion (10 μM; gray traces), in IB_4+ (A) and IB_4- (B) neurons. In C, summary of the effect of quinpirole on the number of APs in IB_4+ and IB_4- small DRG neurons during square pulse stimulation. In D and E, representative AP firing obtained with a ramp current stimulation, recorded before (black traces) and after quinpirole perfusion (10 μM; gray traces), in IB_4+ (D) and IB_4- (E) neurons. In F summary of the effect of quinpirole on the number of APs in IB_4+ and IB_4- small DRG neurons during ramp stimulation.

± 1 APs in control, 9.6 ± 1 APs after quinpirole; n = 12; C_m = 25 ± 3 pF; t(11) = 0.53, P = .61) (Fig. 3E, F).

As positive control DAMGO (1 μM), produced no significant change in the discharge of AP during a depolarizing square pulse (500 ms) in IB_4+ (4.7 ± 1 APs in control, 4.2 ± 1 APs after DAMGO; n = 10; t(9) = 1.37, P = .21) or IB_4- neurons (6.6 ± 1 APs in control, 6 ± 1 APs after DAMGO; n = 8; t(7) = 2.1, P = .07), similar to quinpirole (not shown).

Immunolocalization of D2 DA receptor in the DRG population

To determine the distribution of D2 DA receptor between peptidergic and nonpeptidergic subpopulations of nociceptive DRG neurons, D2 DA receptor was immunolocalized in thin DRG sections (14 μm) of adult rats, and we observed its colocalization with CGRP (peptidergic neuron marker) and IB_4 (nonpeptidergic neurons marker). The antibody raised against D2 DA receptor produced a staining pattern of tiny dots preferentially on or near the membranes of neuron soma (Fig. 4, arrows), but the staining was not homogeneous among all the DRG neurons, since it was absent in many of them. CGRP antibody stained the cytoplasm of small-diameter neurons (< 26 μm) (Fig. 4, arrowhead), and those CGRP-positive neurons were not stained by the marker IB_4 (Fig. 4, arrows), as has been extensively reported (Scherrer et al., 2009). D2 DA receptor staining correlated with IB_4 staining, however some CGRP neurons have scarse D2 DA receptor staining (Fig. 4), suggesting that D2 DA receptor is expressed preferentially in nonpeptidergic DRG neurons. Control sections where 1st antibody was omitted are showed in Fig. 4F-H.

Western blot

To determine the expression of D2 DA receptor in the lumbar DRG, Western blot experiments were done. As reported in earlier reports and above, we found significant expression of D2 DA receptor in the lumbar DRGs (n = 3) (Fig. 5). Rat striatum was used as the positive control of D2 DA receptor expression (n = 3), and the negative control (secondary antibody omission) produced no band staining. The band pattern for D2 DA receptor it was consistent with the MW in previous reports (Galbavy et al., 2013; Stojanovic et al., 2017).

Because D1-like DA receptors have been identified in DRGs (Galbavy et al., 2013), we used an antibody against D1 DA receptor as a positive control and performed Western blot experiments. We found a significant expression of D1 DA receptor in both lumbar DRGs and the rat striatum; the negative control produced no band staining (n = 3) (omission of the secondary antibody).

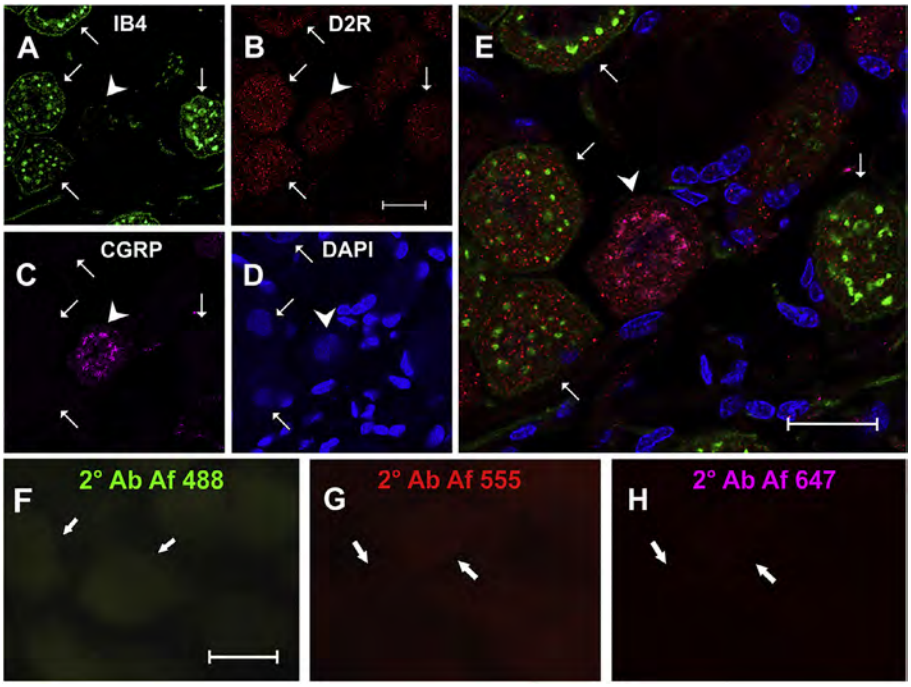

Fig. 4. *Immunostaining of D2 DA receptor in DRG neurons*. Photomicrographs of rat DRG showing in A, IB_4 fluorescence (IB_4; green), B, D2 DA receptor immunoreactivity (D2R; red), C, CGRP immunoreactivity (magenta), D, DAPI fluorescence (blue), E, merge of the images from the same optical fields. Thin arrows indicate IB_4+ small neurons. The arrowhead points to a CGRP-immunoreactive neuron, which is IB_4-. Notice that IB_4+ neurons contain a higher D2 DA receptor immunoreactivity density compared to CGRP-positive neuron. At the bottom (F-H), methodological control of immunostaining omitting primary antibodies, showing the absence of specific immunoreactivity and the background of the second antibodies used, slices were observed with their specific filters (Af, Alexa fluor). Scale bar: 20 μm. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

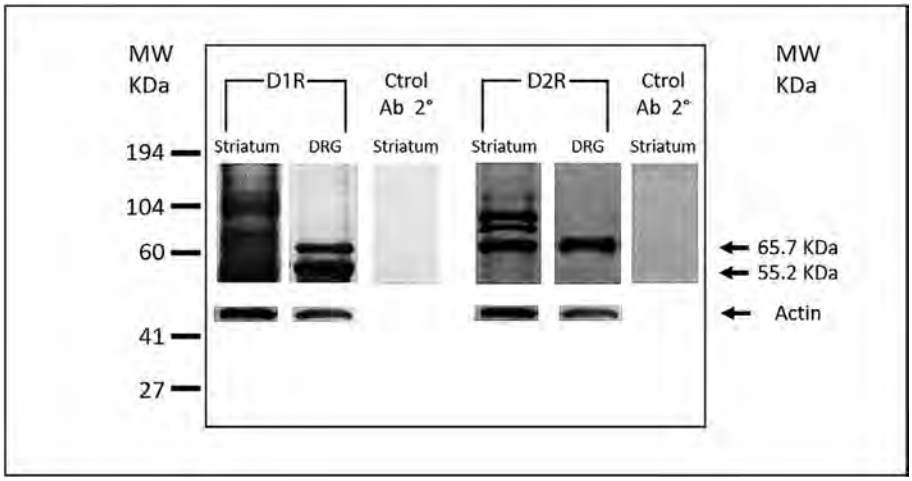

Fig. 5. *D1 and D2 DA receptor protein expression in lumbar DRG neurons*. Western immunoblot analysis with antibodies against D1 and D2 DA receptors of membrane protein extracts from lumbar DRG neurons. Striatum membranes were used as a positive control. As loading control actin was used. For the negative control, the secondary antibody was omitted.

Behavioral tests

Finally, we tested the D2/D3 agonist drug pramipexole (doses tested: 1, 10, and 30 nmol). The use of pramipexole only in the behavioral tests was aimed at evaluating whether a clinically approved D2-like agonist produced antinociceptive effect similar to those of the gold standard D2-like agonist quinpirole, tested in our previous behavioral studies (Almanza et al., 2015; Mercado-Reyes et al., 2019). This experiment is of clinical relevance, as positive results could encourage the potential usage of D2-like agonists as analgesic adjuvants at the spinal cord level.

Pramipexole i.t. administration reached its maximum antinociceptive effect after 15 min and disappeared during the experiment (within 2 h). Pramipexole 30 nmol i.t. administration produced a significant increment of 43 ± 14% in the PWL in mechanonociceptive tests (n = 8; two-way ANOVA, $F_{4, 35} = 4.125$; $P = .002$) (Fig. 6A), while 1 and 10 nmol i.t. produced nonsignificant changes in the PWL. In the thermonociceptive test, pramipexole produced no effect in the PWL at the same doses tested in mechanonociception (Fig. 6B), consistent with the findings previously reported for quinpirole (Almanza et al., 2015). AUC analysis yielded the same conclusions (One-way ANOVA, $F_{4, 30} = 2.75$; $P = .04$; Fig. 6C-F).

Because there was a significant expression of D1-like receptors in DRGs, we tested whether i.t. administration of SKF-38393 (highly selective D1-like agonist) at a high dose (30 nmol) would modify both mechano- and thermonociceptive responses. After SKF-38393 i.t. administration, there were no changes in the PWL from either nociceptive test at any evaluated time (Fig. 6A, B). This finding was best represented in the maximum effect and AUC analysis (Fig. 6C-F).

DISCUSSION

We found that the D2-like DA receptor agonist, quinpirole, inhibits the Ca^{2+} influx in a set of small IB_4+ DRG neurons, mainly through Ca_V 2.2 channels, those neurons are predominantly associated with

INFORME DE LABORES 2019

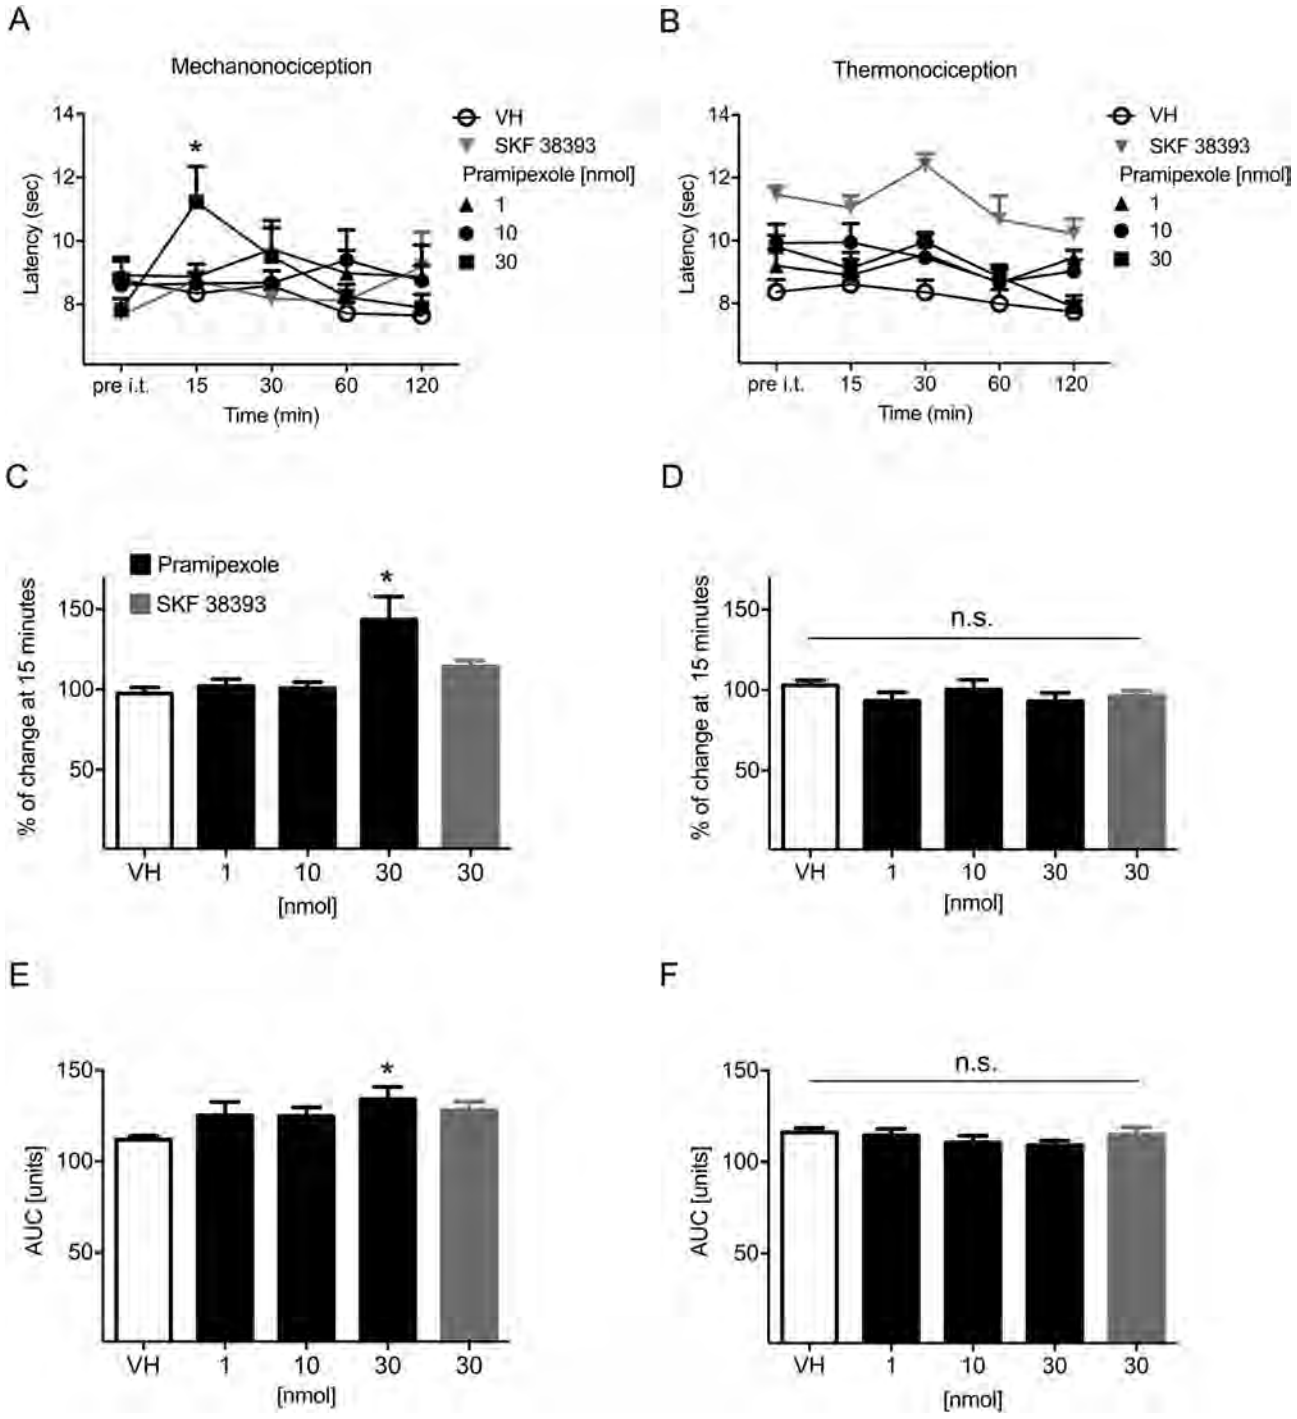

Fig. 6. *The effects of pramipexole and SKF 38393 on the mechanonociceptive and thermonociceptive test*. In A and B, time courses of the effect of i.t. application of vehicle (VH), pramipexole (1, 10 and 30 nmol) and the D1-like DA receptor agonist (SKF 38393, 30 nmol) on PWL in mechano- and thermonociceptive tests, respectively. In C and D, latencies percentage of change (normalized to the basal latency) of VH, pramipexole and SKF 38393 obtained 15 min after i.t. administration in mechano- and thermonociceptive tests. In E and F, area under the curve (AUC) from A and B graphs for each drug and VH in mechano- and thermonociceptive tests, respectively. * denotes significant differences *versus* VH ($P < .05$, one-way ANOVA).

mechanonociception. Western blot revealed a significant expression of D2 DA receptors in the lumbar DRG and immunofluorescence experiments showed that D2 DA receptors were expressed mainly in IB_4+ small DRG neurons. Interestingly, pramipexole produced spinal antinociception in a similar fashion to quinpirole. Our results explain, at least in part, why D2-like receptor agonists produce antinociception specific on mechanonociceptive stimuli.

D2-like DA receptor agonists produce antinociception in different pain models (Tamae et al., 2005; Cobacho et al., 2010, 2014; Rodgers et al., 2019) and clinical con-

ditions that involve intense pain (Dickey and Minton, 1972; Nixon, 1975; Kernbaum and Hauchecorne, 1981; Ertas et al., 1998). Some studies have been done to determine the mechanism by which DA receptor agonists produce antinociception (Fleetwood-Walker et al., 1988; Tamae et al., 2005; Charbit et al., 2009; Taniguchi et al., 2011; Lu et al., 2018), but, at least at the spinal cord level, it is not completely understood.

Neurons from the dorsal horn and DRG express DA receptors; there are evidences that supports the presence of D2-like and D1-like DA receptors in both structures (Xie et al., 1998; Zhu et al., 2007; Barraud et al., 2010; Kawamoto et al., 2012; Galbavy et al., 2013). Our previous work suggests that the distribution of DA receptors in DRG neurons is not homogeneous, and DA receptors must be expressed predominantly in mechanonociceptive neurons (Almanza et al., 2015; Mercado-Reyes et al., 2019).

Results in this work provide evidence that D2-like DA receptor agonist inhibits both, the rise of transient $[Ca^{2+}]_i$ induced by high-K^+ depolarization, and the HVA-I_{Ca} in a significantly higher proportion of IB_4+ neurons than IB_4- neurons. IB_4 stains nonpeptidergic DRG neurons population denominate as IB_4+, its activation mediate mechanonociception (Price and Flores, 2007; Cavanaugh et al., 2009 ; Havelin et al., 2017). While peptidergic that are not stained by IB_4 (IB_4-), mostly express the heat-sensing receptor TRPV1 (Cavanaugh et al., 2009; Havelin et al., 2017) and mediate the thermonociception. Although, grouping neurons by their binding to IB_4 is not perfect to classify neurons by their physiological role (thermonociceptive, mechanonociceptive, *etc.*), and it is less exact in rats than in mouse (Price and Flores, 2007), there is a clear trend of the quinpirole effect to inhibit Ca^{2+} current in those neurons that bind IB_4, which has been related to transduced mechanical nociception (Cavanaugh et al., 2009; Le Pichon and Chesler, 2014). The Ca^{2+} microfluorometry and the electrophysiological data agree with the behavioral effect of the i.t. delivery of D2-like DA receptor agonists (quinpirole in previous work and pramipexole in this report) in nociceptive tests (Cobacho et al., 2014; Almanza et al., 2015).

The immunofluorescence data further support our idea of D2-like DA receptor expression in a population of neurons that are associated with mechanonociception; our results show higher expression of D2 DA receptor mostly in IB_4+ neurons, which could explain the specific antinociception seen in the previous behavioral data and agrees with our findings in Ca^{2+} imaging and patch-clamp experiments.

VGCCs are expressed in the soma and in nerve terminals of DRG neurons, where they regulate neurotransmitter release in the presynaptic terminals of the dorsal horn in the spinal cord through $Ca_V2.2$ channels. In this work, our results show that the major effect of quinpirole on the electrophysiological properties of DRG neurons was the inhibition of HVA-I_{Ca}. Thus, our results support the idea that Ca^{2+} entry through $Ca_V2.2$ channels is reduced due to the activation of D2-like DA receptors, and this can be the presynaptic mechanism by which quinpirole produces –at least in part- its antinociceptive effect when delivered i.t.

VGCC modulation or blocking in nociceptive DRG neurons is one of the most sought-after targets for analgesic drug development. The U.S. Food & Drug Administration (FDA) has approved drugs such as opioids, gabapentinoids and ziconotide that produce analgesia by reducing the HVA-I_{Ca} in DRG neurons (Sluka, 1998; Hendrich et al., 2008; Scherrer et al., 2009). In agreement with the inhibition of HVA-I_{Ca} in DRG by quinpirole shown here, similar results in other neuronal types have been reported (Ramanathan et al., 2008; Kline et al., 2009).

In DRG nociceptors, $Ca_V2.2$ channels are associated with the neurotransmitter release to the spinal dorsal horn and not directly with the neuronal excitability modulation (Bao et al., 1998; Altier and Zamponi, 2004; Takasu et al., 2016); probably explaining why the N-type Ca^{2+} channels inhibition by quinpirole did not modify the neuronal discharge pattern.

T-type Ca^{2+} channels have been described in both, small and medium size DRG neurons and are associated with cellular excitability regulation, its activation determines the after-depolarizing potential which could lead to a burst firing of action potentials. Modulation of these channels would affect the neuronal discharge pattern (Todorovic and Jevtovic-Todorovic, 2007; François et al., 2015). Our results show that quinpirole has no apparent effect on DRG nociceptor excitability, nevertheless, it is important to consider that in our current-clamp conditions, at the membrane potential of about −60 mV, most of T-type channels are in inactivated-state, so, from the current clamp results we can not to determinate if quinpirole had or not effect on them, ultimately changing the neuronal discharge pattern. However, quinpirole exhibits two traits of the mu-opioid agonists: it produces significant inhibition of $Ca_V2.2$ channels (Taddese et al., 1995; Baillie et al., 2015), and it produces modest changes in the electrophysiological firing properties of small DRG neurons (IB_4+ and IB_4- populations, as shown in this work), suggesting an analogous mechanism of antinociception.

Previous studies using DA at 10–100 μM showed a significant inhibition of HVA-I_{Ca} in almost all small-diameter DRG neurons of rat and chicken (Marchetti et al., 1986; Formenti et al., 1998), but DA at those concentrations is an agonist of other amine receptors, particularly α-adrenergic receptor (Cornil and Ball, 2008; Cilz et al., 2014), which are abundant in small-diameter DRG neurons (peptidergic and nonpeptidergic nociceptors). It is worth noting that α-adrenergic agonists (for example, clonidine) produce I_{Ca} inhibition and antinociception when they are administered i.t. (Eisenach et al., 2005; Nguyen et al., 2017). In our work, quinpirole only produced I_{Ca} inhibition in ~50–60% of small-diameter neurons within the IB_4+ population, and it only produced mechanical antinociception. One reasonable conclusion is that D2-like DA receptor expression is confined to the subpopulation of mechanonociceptors (Le Pichon and Chesler, 2014).

INFORME DE LABORES 2019

Our results reveal the cellular mechanism by which mechanonociceptive DRG neurons are inhibited by D2-like DA receptor agonists. They are in agreement with studies reporting the effect of DA or quinpirole on the dorsal horn neurons from superficial layers (Tamae et al., 2005; Taniguchi et al., 2011). Patch-clamp recordings of *substantia gelatinosa* neurons have shown that D2-like DA receptor activation produced the opening of an outward K^+ current, which in turn hyperpolarized the resting membrane potential of dorsal horn neurons, reducing their excitability (Tamae et al., 2005). The frequency of postsynaptic excitatory currents can be reduced by DA application when C-fibers are stimulated, which suggests that D2-like DA receptor activation produces inhibition of the neurotransmitter release (presynaptic inhibition), in lamina I (Lu et al., 2018), and lamina II dorsal horn neurons (Taniguchi et al., 2011), which can be explained with our finding that D2-like DA receptor agonist decreased the HVA-I_{Ca} (most probably $Ca_V2.2$) in IB_4+ small-diameter DRG neurons.

D1 DA receptor activation was linked to reduction of the excitability of small-diameter DRG neurons (Galbavy et al., 2013), but i.t. administration of a high dose of the selective D1/D5 DA receptor agonist SKF-38393 produced no effect on the latency of flexor reflex in nociceptive tests, which is in agreement with a previous report (Tamae et al., 2005). In contrast, D1/D5 DA receptor activation has been linked to the genesis and maintenance of chronic pain conditions, leaving its role in the spinal cord most likely pronociceptive under pathological conditions (Kim et al., 2015; Megat et al., 2018) with little or uncertain participation in the modulation of nociceptive entry in healthy animals.

Thus, differential expression of dopaminergic receptors in primary nociceptive neurons could have physiological and clinical relevance. Our findings are in accordance with the hypothesis of labeled lines for the nociceptive stimulus codification and modulation at the peripheral level (Cavanaugh et al., 2009; Emery et al., 2016). They also provide a better description of the antinociceptive effect of DA at the spinal cord level by suggesting that the mechanism that underlies the mechanical antinociception is elicited by the activation of D2-like DA receptors in primary nociceptive neurons. Together with previous data that demonstrate that D2-like DA receptor agonists produce antinociception in other pain-related CNS structures (López-Avila et al., 2004; Coffeen et al., 2008; Wood, 2008; Pellicer et al., 2010), our work reinforces the hypothesis that dopaminergic agonists could be useful as adjuvants in the treatment of painful conditions resistant to conventional treatments.

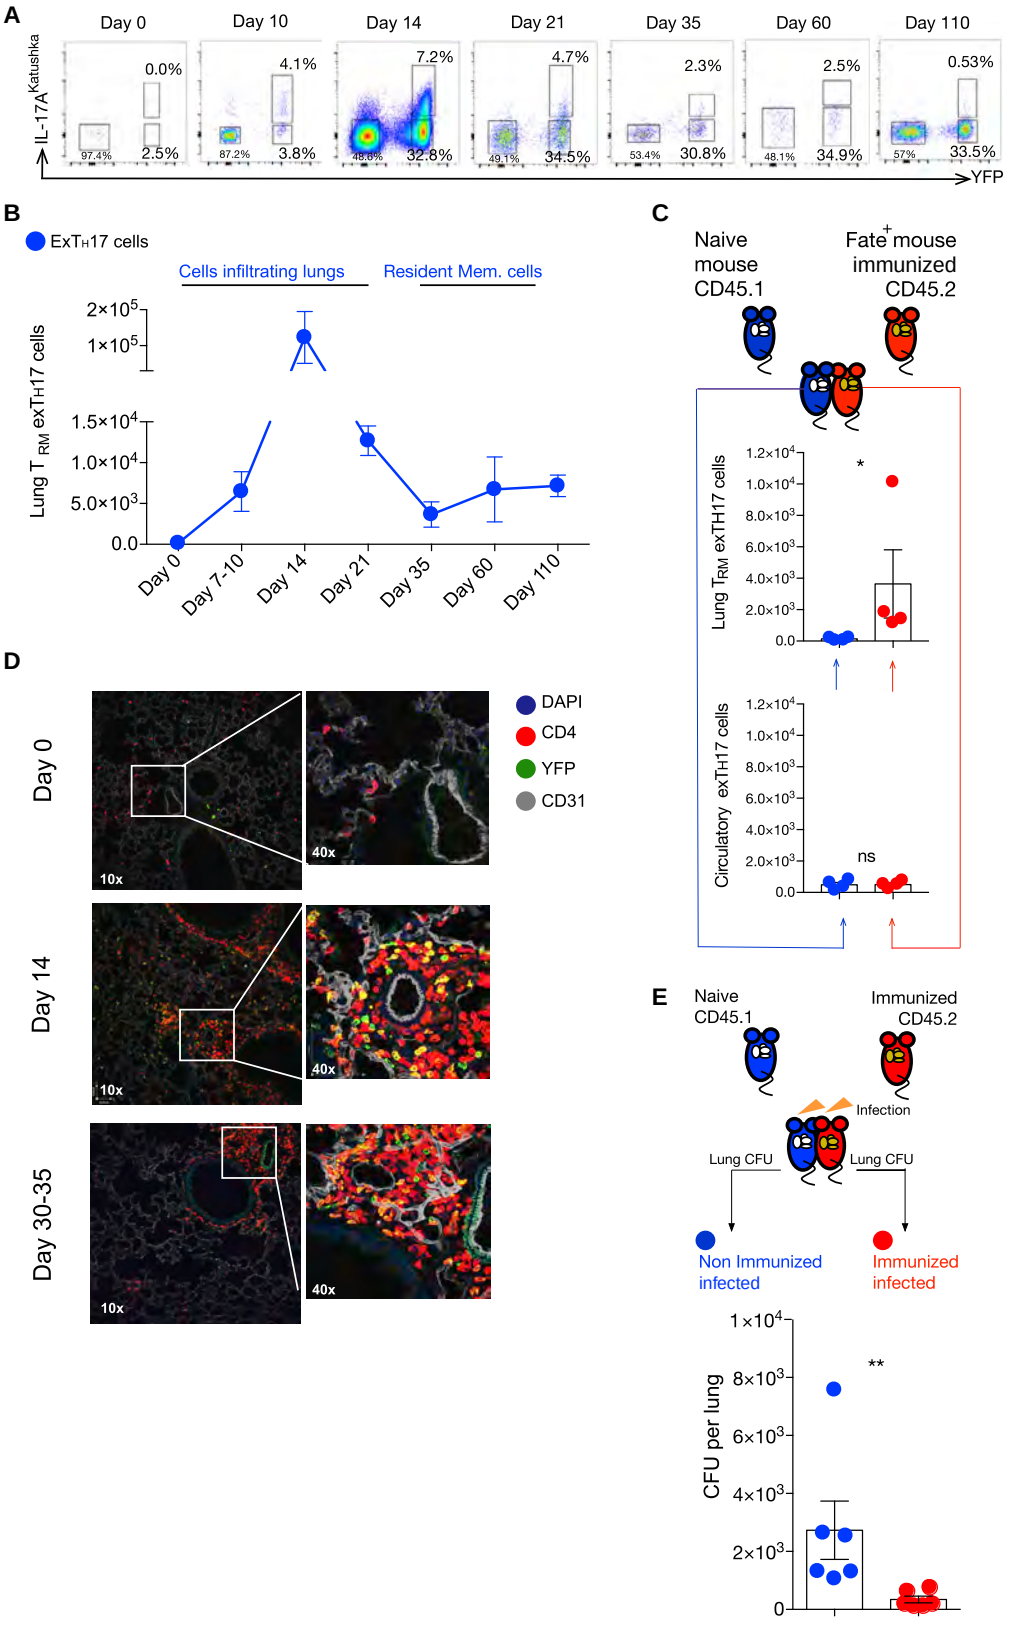
SUMMARY



Adaptive immunity provides life-long protection by generating central and effector memory T cells and the most recently described tissue resident memory T (T_{RM}) cells. However, the cellular origin of CD4 T_{RM} cells and their contribution to host defense remain elusive. Using IL-17A tracking-fate mouse models, we found that a significant fraction of lung CD4 T_{RM} cells derive from IL-17A-producing effector (T_H17) cells following immunization with heat-killed *Klebsiella pneumonia (Kp)*. These exT_H17 T_{RM} cells are maintained in the lung by IL-7, produced by lymphatic endothelial cells. During a memory response, neither antibodies, γδ T cells, nor circulatory T cells are sufficient for the rapid host defense required to eliminate Kp. Conversely, using parabiosis and depletion studies, we demonstrated that exT_H17 T_{RM} cells play an important role in bacterial clearance. Thus, we delineate the origin and function of airway CD4 T_{RM} cells during bacterial infection, offering novel strategies for targeted vaccine design.

INTRODUCTION

Adaptive immunity provides life-long protection from infection by establishing an enduring reservoir of memory cells. Upon infection, CD4 and CD8 T cells undergo clonal expansion followed by a subsequent contraction and ultimately, memory formation (Kaech et al., 2002; Mueller et al., 2013). While central memory T (T_{CM}) cells have long since been known to mainly reside and circulate through secondary lymphoid tissues and effector memory T (T_{EM}) cells to circulate through non-lymphoid tissues, the identification of T_{RM} cells within peripheral organs has opened new concepts about tissue-specific protective immunity (Schenkel and Masopust, 2014).

CD4 T_{RM} cells serve at the frontline at different barrier sites such as vagina (Iijima and Iwasaki, 2014; Stary et al., 2015), lung (Teijaro et al., 2011; Turner et al., 2014; Hondowicz et al., 2016), and skin (Glennie et al., 2017), and their main host-protective mechanism is mediated by the production of effector cytokines such as interferon-γ (IFN-γ) and interleukin-4 (IL-4).

While most of the studies have focused on the biology of virus-specific CD8 T_{RM} cells, basic questions regarding CD4 T_{RM} still remain unanswered. For example: Where do these cells come from; What is the cellular origin of CD4 T_{RM} cells; Which environmental signals maintain them into the tissue; and finally, Are CD4 T_{RM} cells able to rapidly respond to a second challenge?

(legend on next page)

To address these questions, we devised an experimental plan combining the use of two complementary fate reporter mouse models, next-generation T cell receptor (TCR) and single-cell sequencing approaches.

We consider that understanding CD4 T_{RM} cell development and function is imperative, particularly as they may represent the key target cells to design specific and efficacious vaccination against the growing number of antibiotic-resistant bacterial strains emerging in the clinic. This might also help to reduce antibiotic use, avoiding the evolution of antibiotic-resistant bacteria. For instance, there is currently no targeted treatment strategy for carbapenem-resistant *Enterobacteriaceae*-like *Klebsiella pneumoniae* (Kp). This is a leading cause of nosocomial and community-acquired gram-negative bacterial pneumonia, which results in a severe pyrogenic infection with high mortality rates (Falagas et al., 2014). Despite the fact that IL-17A cytokine is critical to deal with Kp infection (Moore et al., 2000; Happel et al., 2005; Chen et al., 2011), the function of T_H17 memory cells have been underestimated because of their short-term survival (Pepper et al., 2010).

Considering all this, we hypothesized that CD4 T_{RM} cells derive from the first wave of effector cells generated during the first encounter with a pathogen. Furthermore, since CD4 T_{RM} cells localize at the site of immunization, we also hypothesized that some of them acquire a poised while others a more plastic status (Lee et al., 2009; Wei et al., 2009; Harrison et al., 2019), which allows them to mount a fast and essential immune response against bacterial infection.

Here, by using an immunization-infection model with different serotypes of *Kp*, we show that a significant fraction of the lung long-lived CD4 T_{RM} cells (ex$T_H17$cells) derive from specific effector T_H17 cells. We observed that exT_H17 T_{RM} cells are maintained by IL-7, which is mainly produced by lymphatic endothelial cells (LECs) in the lung. Finally, we reveal that exT_H17 T_{RM} cells are important players that can resist an antibiotic-resistant strain of Kp.

RESULTS

T_{RM} Cells Can Derive from Effector Cells and Protect against Carbapenem-Resistant Klebsiella Pneumoniae Infection

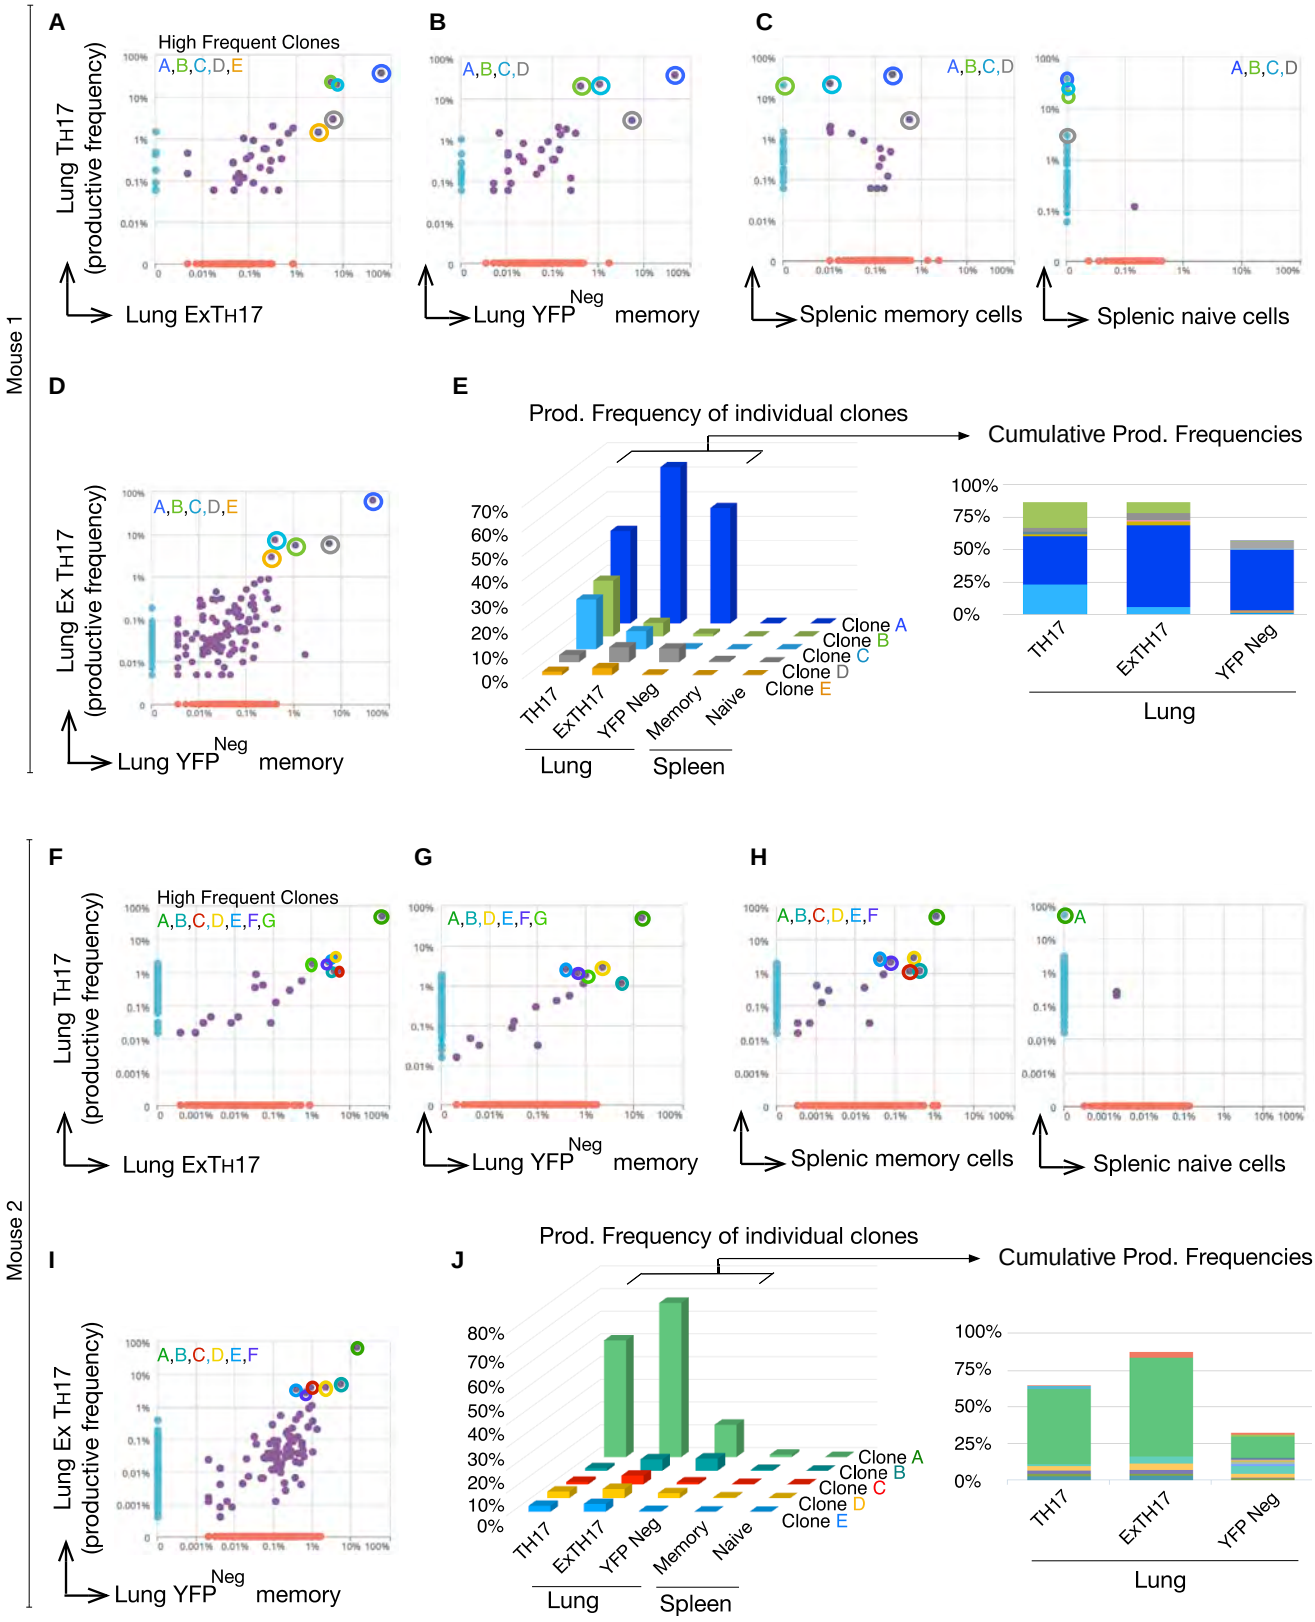
We started by characterizing the kinetics of the development of lung T_{RM} cells. To this end, wild-type (WT) mice were immunized twice with heat-killed serotype 2 *Klebsiella pneumoniae* (Figure S1A), and the presence of CD4 T_{RM} cells was evaluated at multiple time points. An *in vivo* antibody (Ab)-labeling technique was used to differentiate between circulatory and lung-infiltrating CD4 T cells (Anderson et al., 2014). Lung-infiltrating CD4 T cells began accumulating as early as day 5 post-immunization and persisted through day 110 (Figure S1B). CD69 and CD103 have been used as markers for T_{RM} cells. We found that CD4 T_{RM} cells were $CD103^-$ but characterized by high levels of CD69 expression compared with circulatory CD4 T cells (Figures S1C and S1D). Similar to classic CD8 and CD4 memory formation, lung-infiltrating CD4 cells underwent robust expansion upon immunization, followed by an acute contraction phase. Then, a stable lung T_{RM} CD4 population was observed during the memory phase (Figure S1E).

We next aimed to further characterize the origin of T_{RM} CD4 cells, a point that still remained elusive. T_H17 cells have previously been shown to provide protection against Kp infection (Ye et al., 2001; Chen et al., 2011); however, it is unclear whether these cells are short lived and whether they contribute to the memory pool (Pepper et al., 2010; Chen et al., 2011; Muranski et al., 2011). Considering the plasticity of T_H17 cells and instability of IL-17A production, their main marker, one possible explanation for the unknown origin of CD4 T_{RM} cells could be that T_H17 cells lose the expression of their signature cytokine, becoming "exT_H17" cells, when they mature into long-lived memory cells. We therefore used the *Il17a* $Fate^+$-mapping mouse model (Gagliani et al., 2015), which allowed us to track the fate of T_H17 cells independently from the actual expression of IL-17A and from the need of *in vitro* re-stimulation. To generate these mice, $Il17a^{CRE}$ crossed with a $R26STOP^{flox/flox}$ YFP ($R26^{YFP}$) (Hirota et al., 2011) were further crossed with a triple-reporter mouse strain, consisting of $Il17a^{Katushka}$ $Il10^{eGFP}$ $Foxp3^{RFP}$ alleles (Gagliani et al., 2015). In addition, the $Fate^+$ mice allowed us to exclude Foxp3 and IL-10-producing cells from our analysis. By using these mice, we observed that Kp immunization resulted in the generation of T_H17 and exT_H17 cell populations, with the latter persisting in the lung as a population of T_{RM} cells for at least 110 days (Figures 1A and 1B).

To specifically track T_H17 cells generated in response to Kp immunization, rather than all cells with a history of IL-17A expression, we took advantage of an inducible *Il17a* fate model (Gagliani et al., 2015). $R26^{YFP}$ mice were crossed with $Il17a^{eGFP\text{-}Cre\text{-}ERT2}$ mice, such that cells expressing *Il17a* are labeled GFP^+YFP^+ upon tamoxifen administration and persist as a $GFP^{neg}YFP^+$ population after the expression of *Il17a* is

Figure 1. Origin and Function of T_{RM} exT_H17 Cells

(A and B) Dot plots show (A) percentage of T_H17, exT_H17, and YFP^{neg} $IL\text{-}17^{neg}$ cells and (B) absolute number of T_{RM} exT_H17 cells in lungs at different time points after immunization in $Fate^+$ mice (gated on CD4 *in vitro*$^+$ CD4 *in vivo* ^{neg} TCR-β^+ $Foxp3^{neg}$) (n = 4 per time point). One out of two independent experiments is shown.



(C) Naive $CD45.1^+$ and day 35 immunized $Fate^+$ $CD45.2^+$ mice were surgically joined for 3 weeks. Before sacrifice, the anti-CD4 antibody was injected to distinguish T_{RM} and circulating cells. The graph shows the absolute number of lung T_{RM} $CD45.2^+$ and circulatory exT_H17 cells in naive CD45.1 mice (blue) and in $Fate^+$ immunized mice (red).

(D) Representative immunofluorescent sections of lungs from naive (day 0) and immunized mice (day 14 and day 30) showing the presence of CD4 T cells (red) and exTh17/Th17 cells (yellow) surrounding the airways only in the lungs of immunized mice. AW, airway; BV, blood vessel; blue: DAPI, gray: CD31 (n = 3 per time point)

(E) Parabiotic pairs were infected with live carbapenem-resistant *Kp* 3 weeks after surgery. The graph shows the CFU count in total lung 24 h after infection of naive-infected (blue) or immunized-infected (red). Each dot represents one mouse. Data are cumulative of 2 experiments.

Data are represented as mean ± SEM. Mann-Whitney U test; ns (non-significant); *p = 0.0286; **p = 0.0022.

See also Figures S1, S2, and S3.

(legend on next page)

terminated. As expected, Kp immunization resulted in the induction of a newly generated T_H17 cell population (Figure S1F). Notably, 60 days after immunization most of these cells lost *Il17a*^{eGFP} expression and persisted as YFP$^+$ exT_H17 cells in the lung of immunized mice (Figure S1G).

To test whether the accumulation of T_{RM} was associated with long-term protection, the immunized mice were infected with a second serotype of live *K. pneumoniae*, characterized as being resistant to carbapenems (Figure S2A). Immunized mice showed protection against carbapenem-resistant Kp compared with non-immunized mice (Figure S2B).

CD4 T cells, antibodies, and γδ T cells are all important components of the immune response against Kp. However, whether memory T cells alone are sufficient to orchestrate a proper immune response, especially at the early phase of memory activation, remains unknown. Here, we found that despite the absence of B cell and γδ T cells—using genetically deficient mice—immunized animals were still more efficiently protected from acute live carbapenem-resistant Kp infection than non-immunized controls (Figures S2C and S2D).

Next, to further test whether exT_H17 cells were residing in the lung as bona fide T_{RM} cells, we performed parabiosis experiments with naive WT CD45.1$^+$ and immunized Fate$^+$ CD45.2$^+$ mice in combination with an *in vivo* Ab-labeling technique. Naive CD45.1$^+$ and immunized CD45.2$^+$ mice were surgically paired, and 3–4 weeks later we observed shared specific Kp antibodies and CD4 T cells in the circulation (Figures S2E–S2G). We observed that, although the two mice shared memory exT_H17 T cells in circulation, the large majority of exT_H17 cells were present in the lungs of the immunized Fate$^+$ mice and not in the lungs of the naive WT mice (Figure 1C). In addition, immunofluorescent imaging of lungs from immunized mice showed that exT_H17 cells (depicted by yellow) resided in close proximity to the airways and blood vessels at 14 and 30–35 days after immunization forming a potential network of tissue resident cells (Figure 1D).

Finally, to test the hypothesis that the observed resident cells act as the crucial mediators of tissue-specific adaptive immunity, we conducted parabiosis studies infecting both naive and immunized mice with antibiotic-resistant Kp. Despite displaying Kp-specific antibodies and circulatory memory cells, the respective naive mice of the joined pairs failed to efficiently clear live carbapenem-resistant Kp infection. In contrast, we found a very low bacterial burden in the immunized partners (Figure 1E). Moreover, we observed that when the recruitment of memory cells from lymphoid organs is impaired, using FTY720 (S1PR1 antagonist that blocks lymphocyte egress from lymph nodes), the immunized mice still appeared to be more protected compared with naive mice (Figure S2H).

We extended our findings to different pathogens and found long-lived exT_H17 cells after *Candida albicans* and Bacillus Calmette-Guérin (BCG) infections (Figure S3), supporting the hypothesis that the longevity and presence of T_H17 effector-derived T_{RM} cells not only occur in the Kp setting but they are also generated in other infections where IL-17A plays an important role (Khader et al., 2007; Igyártó et al., 2011).

Taken together, these data show that effector T_H17 can give rise to T_{RM} cells and tissue resident cells play a key protective role in the early phase of *Klebsiella pneumoniae* infection.

TCR Specificity and Transcriptome Analysis of Lung T_{RM} Cells

The expansion of certain clones in response to a bacterial infection is a prototypical feature of a memory response. To test whether the development of these T_{RM} cells follows this classic path, we sequenced the CDR3 region of the TCR-β genes of T_H17 and exT_H17 cells present in the lung 35 days after immunization. Thus, this CDR3 sequencing also allowed us to elucidate the clonal origin of exT_H17 T_{RM} cells.

We found that the small population of T_H17 cells present at day 35 post-immunization was represented by highly restricted oligo-clonal expanded TCR clones, and these clones were shared with exT_H17 cells (Figures 2A and 2F), further indicating a common origin between these two populations. Then, we selected the most expanded clones among lung T_H17 cells and tracked them in all the other populations of T_{RM} cells in the lung and also in naive and memory cells in the spleen (Figures 2B, 2C, 2E, 2G, 2H, and 2J). When we evaluated the clonality of those lung T_{RM} cells that never expressed IL-17A (YFP^{neg}), we found that they share some degree of clonality with both T_H17 and exT_H17 T_{RM} cells, but to a lower degree compared with what T_H17 and exT_H17 T_{RM} cells share between one another (Figure 2B, 2D, 2G, and 2I). This suggests that both type of cells were generated during the effector immune response, but unknown differences led them to become YFP^{pos} or YFP^{neg} cells. Finally, some of the expanded clones represented in the T_H17 cells were also present, albeit at a very low frequency in splenic CD4 memory cells, but they were not detectable in naive CD4 T cells, denoting the generation of a specific and systemic immune response after immunization (Figures 2C and 2H).

Tissue and cell-type-specific expression of genes, including T_{RM} "core" genes, can be commonly suggestive of corresponding specific functions and cell origin. To evaluate the presence of a tissue-related specific gene profile in memory cells residing at the lung or lymph nodes, we performed RNA sequencing. We hypothesized that, based on their location, different transcriptomes will be expressed by these memory CD4 T cell populations. We

Figure 2. TCR-β Sequencing of Lung T_{RM} Cells

(A–C and F–H) TCR-β sequencing of (A and F) lung T_H17 T_{RM} versus lung exT_H17 T_{RM} cells, (B and G) lung T_H17 T_{RM} versus lung YFP^{neg} T_{RM}, and (C and H) lung T_H17 T_{RM} versus splenic CD4 memory cells and versus splenic CD4 naive cells at day 35 after immunization in 2 different mice.

(D and I) TCR-β sequencing of lung exT_H17 versus lung YFP^{neg} cells at day 35 after immunization in 2 different mice. The dots plots graphs show the common shared CDR3 amino acid sequences of TCR-β chains between all the populations. The most expanded clones among T_H17 cells were colored and followed across all the comparisons between different populations.

(E and J) The bar graphs on the left show percentage of the most expanded clones in each population. The bar graphs on the right show the cumulative productive frequency of the most expanded clones in lung T_{RM} cells. The colors of the clones followed the same colors used for the dot plots graphs.

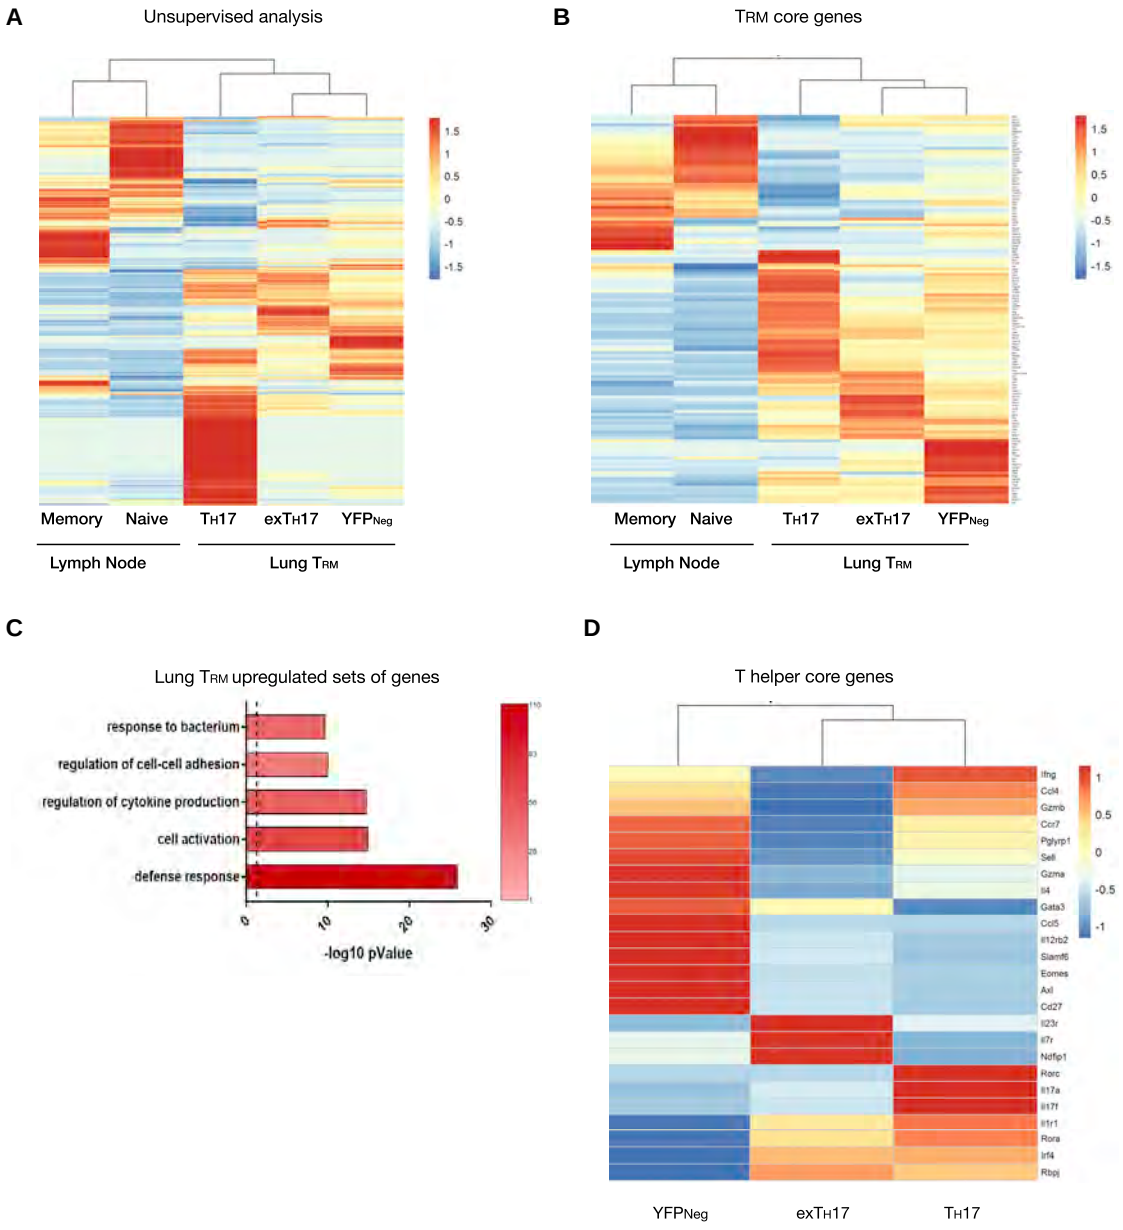


Figure 3. RNA Sequencing of Lung T_{RM} and Lymph Node Memory and Naive CD4 Populations Illustrates Key Features of Lung T_{RM} Populations

(A) Heatmap of genes significantly differentially expressed (>4-fold cutoff) between the lymph node and lung populations.

(B) Heatmap of a selected subset of genes known to be involved in tissue resident memory cell-biology.

(C) Bar graph of gene ontology assignments of genes overexpressed 4-fold in lung T_{RM} cells relative to lymph node memory cells. The dashed line represents p = 0.05, Fisher's exact test. The intensity of the color bar on the right indicates the amount of genes in each pathway.

(D) Heatmap of a selected subset of genes known to be involved in T helper subset and memory biology.

profiled the transcriptome of draining lymph node (LN)-naive CD4 T cells, memory CD4 T cells, and the 3 populations of T_{RM} cells present in the lung 35 days after immunization (T_H17, exT_H17, and YFP^{neg} cells).

We used either an unsupervised list of genes that were significantly differentially expressed (>4-fold) (Figure 3A; GEO: GSE130446) or a core of T_{RM} signature genes (Table S1; Figure 3B; Wakim et al., 2012; Mackay et al., 2013; Pan et al., 2017) to test similarities and differences among the transcriptomes of these cell populations. We found that lung T_{RM} cells (T_H17 cells, ex-T_H17 and YFP^{neg} cells) share a similar pattern of gene expression, which, in contrast, differs from the expression pattern of the peripheral memory LN cells, independently of the approach used to analyze them (Figures 3A and 3B).

To search for different functional features among all lung T_{RM} cells and peripheral LN memory cells, we performed gene

(legend continued on next page)

ontology (GO) analysis of genes upregulated in lung T_{RM} cells using DAVID (Huang et al., 2009). Interestingly, GO terms showing statistically significant enrichment were mainly related with immune process such as defense response, cell-to-cell adhesion, cell activation, regulation of cytokine production, and response to bacteria (Figure 3C). All this suggests that lung T_{RM} cells present a profile more focused toward a rapid immune response compared with peripheral memory cells.

We then focused on the different populations of lung T_{RM} cells and evaluated the expression of a selected list of genes involved in specific T-helper cell subset and memory T cell-biology. Interestingly, based on the expression of the genes from this list, we found that T_H17 and exT_H17 cells cluster more closely together than to the YFP^{neg} cells (Figure 3D; Table S2). In particular, the expression patterns of *Il1r*, *Rora*, *Irf4*, and *Rbpj* suggested that some of the exT_H17 T_{RM} cells have acquired a prime signature state that could allow them to rapidly respond by producing IL-17.

Interestingly, we also found that Ndfip1, which was recently shown to be essential to balance the potential tissue related pathogenicity of T_H17 cells (Layman et al., 2017), was highly expressed in exT_H17 cells. We also observed that the expression of *Il7r* was higher in exT_H17 cells than in YFP^{neg} cells. Finally, regarding the population that never activates the production of *Il17a* (YFP^{neg} cells), the expression of a $T_H1/2$-memory signature transcriptome (e.g., *Eomes*, *Ifng*, *Ccr7*, *Sell*, *Il4*, *Gata3*, *Ccr3*, *Ccr5*) suggests that these cells might be a heterogeneous population composed of T_H1 and T_H2 effector-derived memory cells (Figure 3D; Chang et al., 2007; Bannard et al., 2009).

Effector-Derived T_{RM} Cells Depend on IL-7, which Is Produced by Lung LECs

We next interrogated the possible mechanisms that might be involved in the maintenance of exT_H17 T_{RM} cells in the lung. The residency and establishment of T_{RM} cells at peripheral tissues correlates with downregulation of KLF2 and S1PR1 and the concomitant inability to follow a gradient of S1P and leave the tissue (Carlson et al., 2006; Skon et al., 2013). Consistently, lower levels of KLF2 and S1PR1 expression were found in lung T_{RM} exT_H17 cells and in the small population of T_H17 cells compared to CD4 splenic memory or naive CD4 T cells from $Fate^+$ immunized mice (Figure 4A).

Then, to evaluate whether a continuous supply of circulating lymphocytes is required for the maintenance of the pool of CD4 T_{RM}, we treated day 35 immunized mice with FTY720. Decreased numbers of circulating total white blood cells were found after 2 weeks of FTY720 treatment, while, by contrast, the total number of CD4 T_{RM} and exT_H17 T_{RM} cells in the lung remained unchanged (Figure 4B). All these data pointed toward *in situ* mechanisms that might sustain the survival of CD4 T_{RM} cells. Therefore, we investigated the possible role of the cytokine milieu. Both IL-7 and IL-15 signaling are understood to be key mediators of CD4 T cell homeostatic proliferation, a mechanism that could explain the long-term and circulatory independent maintenance of T_{RM} (Mackay et al., 2013; Iijima and Iwasaki, 2014; Adachi et al., 2015; Hondowicz et al., 2016). In line with the data obtained from the RNA sequencing experiment, we found that a fraction of T_{RM} exT_H17 cells expressed IL-7Rα, but they lacked IL-15Rβ expression (Figures 4C and 4D). To test the role of IL-7 in the maintenance of T_{RM} exT_H17 cells, we intranasally administered anti-IL-7 antibodies (Abs) or isotype control antibodies into immunized mice. The local treatment with anti-IL-7 Abs did not diminish CD4 T cell numbers systemically (Figure S4A). However, the number of lung T_{RM} exT_H17 cells was reduced after IL-7 blockade (Figure 4E).

Then, considering the key role of IL-7, we also investigated the cellular source of IL-7 in the lungs of immunized mice. By performing single-cell RNA sequencing of total lung cells and unsupervised clustering (Figure S4B; GEO: GSE131450), we observed first that *Il7* was preferentially expressed by lymphatic endothelial cells (LECs, Figure 4F) and second that the percentage of $Il7^+$ LECs increased in immunized mice (Figure 4G). By using $IL\text{-}7^{GFP/+}$ reporter mice, we found that lung CD4 T_{RM} cells are located in close proximity to $IL\text{-}7^+$ LECs in the lung of *Klebsiella* immunized mice (Figure 4H). Finally, as IL-7 is known to promote the homeostatic proliferation of T cells, $Fate^+$ mice were immunized and 60 days later given bromo-2-deoxyuridine (BrdU) in the drinking water for 2 weeks. Approximately 20% of exT_H17 T_{RM} cells were labeled with BrdU, suggesting that homeostatic proliferation plays a role in maintaining CD4 T_{RM} cells (Figure 4I).

Function of Effector-Derived T_{RM} Cells

T_H17 cells are a distinct subset of effector CD4 T cells with a degree of plasticity (O'Shea and Paul, 2010; Schlapbach et al.,

(C and D) Histograms show the expression of CD127 and CD122 in lung exT_H17 T_{RM} cells (red line) 60 days after immunization and in total spleen CD4 cells (blue line). For CD127 unstained control (grey line) is shown. CD122 expression in total CD8 spleen cells is shown as a positive control (grey line) (n = 4 mice). One out of 2 independent experiments is shown.

(E) $Fate^+$ immunized mice were intra-nasally treated with anti-IL-7 Ab or with an isotope control on days 35, 37, and 39 after immunization, and the mice were sacrificed on day 40. The graph shows the absolute number of lung exT_H17 T_{RM} cells in the isotype ctrl-treated group (black circles) and in the anti-IL-7-treated group (red circles). Each dot represents one mouse. Three combined experiments are shown.

(F) Single-cell RNA sequencing of total lung tissue cells from immunized mice with total $CD4^+$ cells and circulatory $CD45^+$ removed by fluorescence-activated cell sorting (FACS). Lung cells were profiled by droplet-based scRNA-seq (Drop-Seq). t-distributed stochastic neighbor embedding (t-SNE) plots show 1,500 cells (dots) in a nonlinear representation of the top 50 PCs. Cells are colored by cluster. The clusters were identified by specific genes (Figure S7).

(G) Representation of differentially expressed *Il7* gene by cluster (y axis) in immunized and naive conditions (x axis). The dot size represents the fraction of cells in the cluster that express *Il7*; the dot color represents the intensity of *Il7* expression.

(H) Representative immunofluorescent sections of lungs from B6-non-immunized (left), $IL\text{-}7^{GFP/+}$ non- immunized (middle) or day 35-immunized mice (right). Colocalization of CD4 T cells (red) and $IL\text{-}7^+$ LECs (gray + green) in the lungs of immunized mice. Blue: DAPI, gray: Lyve-1, green: IL-7, red: CD4.

(I) The histogram shows the percentage of lung exT_H17 T_{RM} $BrdU^+$ cells. Each dot represents one mouse. One out of 2 independent experiments is shown.

Data are represented as mean ± SEM. Mann-Whitney U test; ns (non-significant) (B); **p = 0.0082 (E).

See also Figure S4.

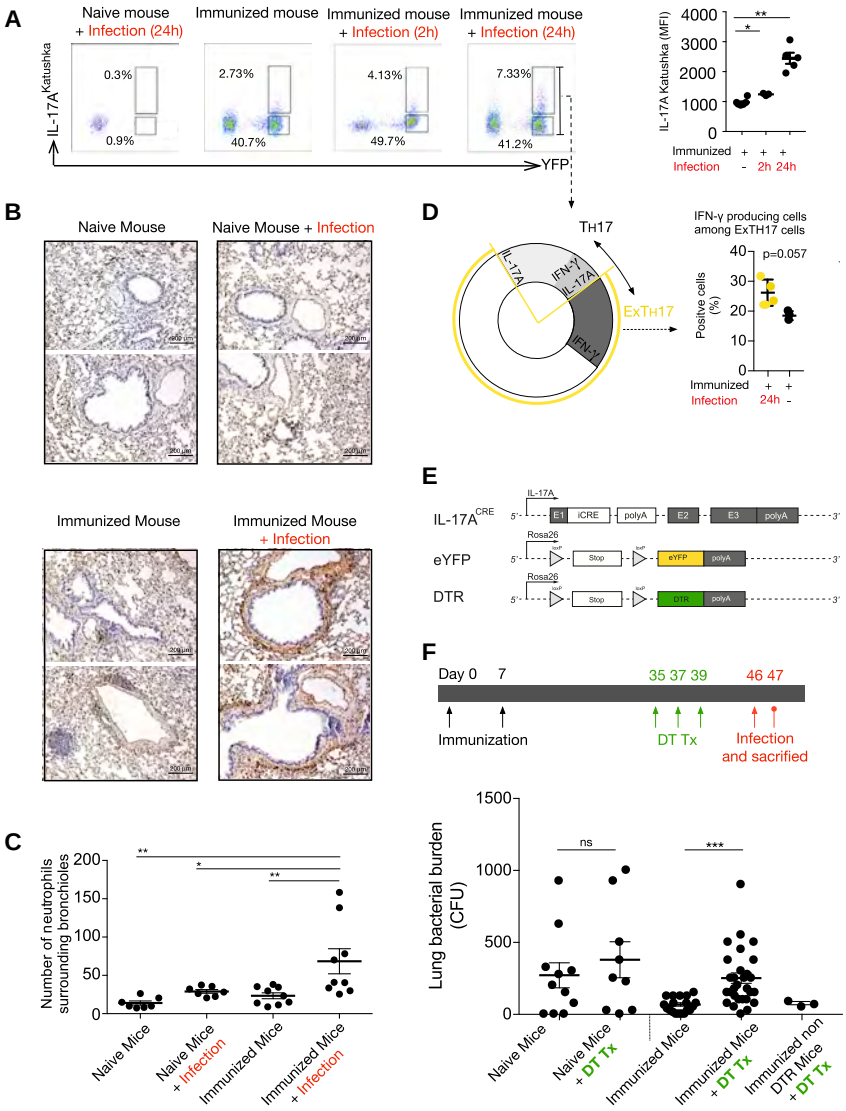

Figure 5. Function of T_{RM} exTh17 Cells

(A) Dot plots show the frequencies of T_H17 T_{RM} and of exT_H17 T_{RM} cells (CD4 *in vitro*$^+$, CD4 *in vivo*^{neg}, TCR-β^+ Foxp3^{neg}, YFP$^+$) in naive + infection mouse, immunized mouse (day 35), immunized mouse + infection (2 h), and immunized mouse + infection (24 h) (n = 3 mice per group). The right graph shows the MFI of IL-17^{kata} in T_H17 T_{RM} cells.

(B) Peroxidase immune staining of mouse Ly6B in naive, naive + infected, immunized (day 35), and immunized (day 35) + infection lungs, 2 h after Kp infection. Representative slides are shown for each group.

(C) Quantification of neutrophils surrounding bronchioles from (B).

(D) Cake graph shows the percentage of INF-γ^+ (dark gray) among the population of YFP$^+$ cells 24 h after infection with live Kp (after PMA-ionomycin stimulation). Double-positive cells (IL-17A$^+$, INF-γ^+ middle gray) and IL-17A$^+$ cells (light gray) are shown separately. The graph on the right shows the percentage of INF-γ^+ single positive cells in immunized + infection (yellow circles) and in immunized mice not infected (day 35 after immunization).

(E) Constructs of Fate-DTR mice.

(F) Scheme depicting the time plan of immunization, DT treatment (DT Tx), and infection of Fate-DTR mice (Top). The graph shows the CFU counts in the indicated groups. For the first 4 groups (from left to right) Fate-DTR mice were used, while for the last group Fate$^+$ immunized mice were used. Each symbol represents one mouse.

Data are represented as mean ± SEM. Kruskal-Wallis ($p < 0.0001$) and post hoc Mann-Whitney U test with Bonferroni correction *p = 0.0238 **p = 0.0043 (A); one-way ANOVA, and post hoc Dunnett *$p < 0.05$; **$p < 0.005$ (C); Mann-Whitney U test (D) and Kruskal-Wallis (p = 0.0009) and post hoc Mann-Whitney U test with Bonferroni correction, ns (non-significant), ***$p < 0.0001$ (F).

See also Figure S5.

2014; DuPage and Bluestone, 2016). However, whether exT_H17 T_{RM} cells can maintain their ability to express their original cytokine profile when re-challenged with antigen remained to be addressed. If so, this could be interpreted as an evolutionary advantage to be able to maintain a population of memory cells at the previously infected barrier to provide a quick response to eventual subsequent infections. We therefore determined the expression of IL-17A and observed that only previously immunized mice show a rapid (i.e., 2 and 24 h) increase in IL-17A^{Kata} expression following infection with carbapenem-resistant Kp (Figure 5A). One feature of T_H17 cells is their ability to recruit neutrophils (Fossiez et al., 1996; Schwarzenberger et al., 1998). In line with this, immunized mice showed a significantly increased number of neutrophils surrounding the bronchial lung barrier, within 2 h after infection (Figures 5B and 5C).

Although IL-17A activity is sufficient to control spread of the bacteria, IFN-γ seems to be necessary to fully promote efficient control of Kp (Happel et al., 2005). In parallel, it has also been shown that T_H17 cells have the ability to acquire a T_H1-like phenotype (Wei et al., 2009; Hirota et al., 2011; Zielinski et al., 2012). We therefore wondered whether some exT_H17 cells were capable of expressing IFN-γ rather than IL-17A upon reencountering bacterial-derived antigens. Our data show that a fraction of exT_H17 cells do not re-express the original cytokine IL-17A but instead IFN-γ within 24 h after infection (Figure 5D). These data reveal that T_{RM} cells also have the ability to maintain a degree of flexibility as other CD4 T cells.

Finally, we wanted to test whether exT_H17 T_{RM} cells and their several functions are necessary to orchestrate the tissue resident memory immune response. We therefore developed a mouse model to delete cells with a history of IL-17A production such as exT_H17 and their inherent ability to rapidly produce IL-17A at a desired time point. We crossed *Il17a*^{CRE} R26^{YFP} *Foxp3*^{RFP} with conditional diphtheria toxin receptor (DTR) mice

(R26STOP$^{flox/flox}$ DTR; referred to here as Fate-DTR) (Figure 5E). In this mouse model, only the YFP^{+} cells express DTR and can therefore be selectively deleted at the time of diphtheria toxin (DT) treatment. We first tested the efficacy of the DT mediated depletion and observed that exT_H17 cells were depleted in the lung after three injections with the toxin (Figure S5A). As expected, $\gamma\delta$ exIL-17 T cells were also deleted. However, they did not appear to play an obvious role during memory response against Kp (Figure S2D).

We then took advantage of this model to test whether other tissue resident cells in the lung (i.e., CD4^{+} YFP^{neg}) are sufficient to provide a reservoir for the generation and in turn the maintenance of exT_H17 T_{RM} cells. Therefore, day 35 immunized mice were treated or not treated with DT and rested for 21 days (Figure S5B). Then, the absolute number of exT_H17 cells and total CD4 T_{RM} cells were evaluated. No new generation or differentiation of exT_H17 cells was observed 21 days after DT treatment suggesting that a new wave of effector CD4 T cells is required to re-establish long-lived exT_H17 T_{RM} cells following depletion (Figures S5C–S5).

Finally, immunized Fate-DTR mice were infected with live carbapenem-resistant Kp and the bacteria burden was tested 24 h later. Mice depleted of exT_H17 cells before infection were impaired in their ability to control bacterial load. As expected, the non-depleted mice, whose lungs still contained exT_H17 T_{RM} cells, were able to effectively control the bacterial infection (Figure 5F). These data suggest that effector-derived T_H17 cells are indeed required to rapidly control this bacterial infection. Naive depleted and naive non-depleted mice were used as controls, and both groups behaved as the immunized exT_H17 cell depleted group. Moreover, immunized Fate^{+} (non DTR) mice were used as additional controls for non-specific DT effects, showing protection after infection.

DISCUSSION

Several studies have focused on the molecules and or transcription factors needed for the arrival and or retention of T_{RM} cells (Mackay et al., 2013; Skon et al., 2013; Mackay et al., 2016). However, whether T_{RM} cells derive from effector T cells remained unclear. Here, we showed that lung-infiltrating CD4 T cells became T_{RM} cells at later time points after *Klebsiella pneumoniae* immunization and protected immunized mice from carbapenem-resistant *Klebsiella pneumoniae* infection. By using two state-of-the-art IL-17A fate mouse models, we demonstrated that effector T_H17 cells were capable of persisting as a long-lived exT_H17 population, creating a resident cellular network in the lung airways. We observed a similar phenomenon, although at a lower magnitude, using other T_H17-induced pathogens such us *Candida albicans* and BCG. Using parabiosis experiments, we showed that T_H17 effector-derived T_{RM} cells persisted in the lung of immunized mice, despite reaching an equilibrium in the circulation of both paired parabionts. Infecting both parabionts or blocking the recruitment of circulatory cells from the periphery, we proved the fundamental advantage to an organism of having a local memory immune response over a systemic memory response.

We sought to compare and contrast the clonality and the whole transcriptome of lung T_{RM} cells versus periphery memory and naive cells. Here, we found that lung T_{RM} cells comprise 3 distinct populations: (1) exT_H17 cells, derived from effector T_H17 cells generated during effector immune response, (2) a low percentage of T_H17 cells, and (3) YFP^{neg} cells or cells that despite their never having been IL-17A producers also became T_{RM} cells. Moreover, the TCR sequencing (TCR-seq) analysis revealed a common clonal origin of T_H17 and exT_H17 T_{RM} cells with highly frequent clones that first expanded then contracted and finally generated a bona fide T_H17 T_{RM} response. The frequency of YFP^{neg} T_{RM} clones is in line with some previous studies where a T_H1 population was also generated during the first immune response against *Klebsiella pneumoniae* (Happel et al., 2005). Additionally, our whole-transcriptomic analysis revealed similarities among all lung T_{RM} cells, distinguishing them from peripheral memory cells. Nevertheless, some effector-derived exT_H17 cells still maintained a "T_H17-prone memory status" (Muranski et al., 2011; Youngblood et al., 2017), which may explain their fast response.

A more detailed analysis of YFP^{neg} T_{RM} cells unveiled possible distinct origins for this population. Based on their T_H1/ T_H2 and T_{CM}-related transcriptome and in line with previous human studies (Sathaliyawala et al., 2013; Becattini et al., 2015), we speculate that some YFP^{neg} T_{RM} cells may have derived from effector/effector memory T_H1 and T_H2 cells and some from central memory cells. However, more studies using polyclonal and combined cytokine fate-mapping systems are needed to clarify the origin of this heterogeneous population of cells. Previous studies, using TCR-seq or skin injections of TCR transgenic T cells have suggested that central memory CD8 T cells are the the origin of skin CD8 T_{RM} cells (Gaide et al., 2015; Kirsch et al., 2015). Our results show that CD4 T_{RM} cells were also able to derive from the first wave of effector cells generated at the beginning of the immune response.

The mechanisms elucidated for CD8 T_{RM} cell maintenance indicate that cytokines, transcription factors, and even some free fatty acid binding proteins could be involved in these processes (Adachi et al., 2015; Mackay et al., 2015; Schenkel et al., 2016; Pan et al., 2017). Nevertheless, little is known about CD4 T_{RM} cell maintenance. We hypothesized that, based on the tissue and the environment where T_{RM} cells are located, different mechanisms will operate to maintain their survival. In our models, we observed that there was no contribution from peripheral memory cells when it comes to maintenance of exT_H17 cells in the lung. By antibody-blocking and by performing single-cell RNA-seq experiments, we demonstrated that IL-7 derived from LECs was needed to maintain the survival and location of lung exT_H17 T_{RM} cells. Our results highlight the importance of stromal cells in the maintenance of exT_H17 T_{RM} cells, resembling similar mechanism by which IL-7 support other cells in the bone marrow (Cordeiro Gomes et al., 2016).

Another key aspect is the mechanisms whereby T_{RM} cells induce protection during infection. Our *in vivo* results are in line with the "primed status" of T_{RM} cells, usually viewed as a front-line branch of the adaptive immune system that "seeds" mucosal tissues. The kinetic experiments suggested that some of the lung exT_H17 T_{RM} cells transcribe high levels of *Il17a* as rapidly as 2 h after challenge with carbapenem-resistant *Klebsiella pneumoniae* infection. Our data are in line with previous

studies where CD4 T_{RM} cells express IFN-γ or IL-4 in their membrane or quickly release these cytokines after viral, parasite, or house dust mite re-challenge to better control infections or contribute to the pathology associated with asthma (Teijaro et al., 2011; Iijima and Iwasaki, 2014; Hondowicz, et al., 2016). In addition some of the lung exT_H17 T_{RM} cells also maintain the flexibility to produce only IFN-γ, the other key cytokine for an efficient response to *Klebsiella pneumoniae*. The plasticity of T_H17 cells is well characterized (Wei et al., 2009; Hirota et al., 2011; Zielinski et al., 2012), but for the first time our data show that the capacity to adapt to the environment is maintained also in exT_H17 T_{RM} cells.

We also hypothesized that the tissue environment created by the reactivation of T_{RM} exT_H17 cells commits neutrophils to extravasate and rapidly clear the bacteria.

One caveat of the functional experiments in which we used DT to delete both exT_H17 and T_H17 T_{RM} cells is that the IL-17A-producing γδ T cells were also deleted. However, using knockout mice for γδ T cells, we showed that γδ T cells do not appear to play a key role during the memory response, therefore supporting a major role for exT_H17 and T_H17 T_{RM} cells during this memory phase. In contrast, our data suggest that γδ T cells play a key role during the first response to the infection in a naive mouse (Figure S2D). Our data therefore support the hypothesis that T_H17 T_{RM} cells and IL-17A γδ T respond to this pathogen at different times of exposure; however, further studies are required to fully dissect the "division of labor" between these two types of IL-17A producer cells during *Klebsiella pneumoniae* infection. All this is also the case for circulatory IL-17A producer memory cells.

Taken together, our results indicate for the first time that a long-lived exT_H17 T_{RM} population originates from polarized T_H17 effector cells. This population is maintained by non-stromal LECs that produce IL-7. Furthermore, we underline the importance of having an effector-derived T_{RM} cell population as frontline cells that together with other T_{RM} cells, mediate the rapid clearance of threatening strains of antibiotic-resistant bacterial infections. We suggest that this cell population plays a central role in the cellular basis of immunological memory.

Finally, our study may hopefully pave the way for future studies in human tissues to design better strategies aimed to deliver more effective vaccines. Hospitalized patients infected with carbapenem-resistant *Klebsiella pneumoniae* do not respond to carbapenem antibiotic treatment and thus represent a serious clinical problem. Our data provide basic knowledge that may provide a possible solution to such a problem: vaccination for prophylaxis of carbapenem-resistant Kp especially in patients at risk.

STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- LEAD CONTACT AND MATERIALS AVAILABILITY
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
  - Mice
  - Heat killed *Klebsiella pneumoniae*
- METHOD DETAILS
  - Immunization and infection with *Klebsiella pneumoniae*
  - *In vivo* labeling of circulating CD4 T cells
  - Lymphocyte Preparation and Flow Cytometry
  - BrdU labeling
  - Tamoxifen, FTY720 and Diphtheria toxin treatments
  - Antibodies and chemicals administered to the mice
  - Immunofluorescence staining
  - Real time PCR
  - K.pneumoniae antibody titers
  - Cutaneous Candida albicans infection
  - Bacillus Calmette-Guérin (BCG) infection
  - Parabiosis
  - RNA sequencing
  - Single cell RNA sequencing
  - CDR3 TCRβ sequencing
- QUANTIFICATION AND STATISTICAL ANALYSIS
  - Statistical Analysis
- DATA AND CODE AVAILABILITY

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Mice

C57BL/6 mice 8–12 weeks of age were obtained from Charles River (USA).

As previously described (*1*) the Fate^{+} model was obtained by crossing the original Foxp3^{RFP} IL-10^{eGFP} IL-17A^{Kata} mice with IL-17a$^{CRE+/+}$ R26YFP$^{+/+}$ mice (kindly provided by Prof B. Stockinger). The iFate mice were generated in our Lab (Gagliani et al., 2015). The iFate mice were used in heterozygosis for the IL-17a$^{IRES\text{-}eGFP\text{-}CRE\text{-}ERT2}$ allele (Gagliani et al., 2015).

ROSA26iDTR were acquired from the Jackson laboratories (007900) and crossed with IL17$^{CRE\ +/+}$ FoxP3 RFP$^{+/+}$ R26STOP$^{flox/flox}$ YFP$^{+/+}$ to obtain the Fate-DTR mice. Heterozygous IL7GFP/+ mice (Miller et al., 2013) were provided by Joao Pereira. We always used females in our studies because it is not allowed to do parabiosis experiments with males.

Animal procedures were approved by the Institutional Animal Care and Use Committee of Yale University

Heat killed *Klebsiella pneumoniae*

K. pneumoniae (Kp) ATCC strain 43816, serotype 2 was expanded over night at 37 C in nutrient broth. 200 ul of the bacterial suspension were added to 50 mL of nutrient broth and grown for 3.5/4 hr at 37 C, allowing the culture to reach log phase. The concentration of Kp was determined by measuring the absorbance at 600 nm. Bacteria were pelleted by centrifugation at 4,500 rpm for 8 min, washed twice in sterile PBS, and re-suspended in 5 mL of sterile PBS. To heat kill the bacteria we incubated the suspension for 2 hr at 70 C. Then we calculate the amount of protein by Biorad kit (DC protein assay) and keep our stock of 1mg/ml of heat killed Kp at −20 C. Cultures in solid nutrient broth confirm that the bacteria were death.

METHOD DETAILS

Immunization and infection with *Klebsiella pneumoniae*

For immunizations, 40 ug of heat killed Kp (43816) were intranasally administered into anesthetized mice (Ketamine/Xylazine (100 mg/kg and 10 mg/kg respectively)) on day 0 and 7 (Figure S1A).

For infections *Klebsiella pneumoniae* BAA-2146 (NDM1+) (ATCC) was expanded over night at 37 C in nutrient broth. 200 ul of the bacterial suspension were added to 50 mL of nutrient broth and grown for 3.5/4 hr at 37 C, allowing the culture to reach log phase. The

concentration of Kp was determined by measuring the absorbance at 600 nm (OD_{600} = 2 resemble $2x10^9$ bacteria/ml). Bacteria were pelleted by centrifugation at 4,500 rpm for 8 min, washed twice in sterile PBS, and re-suspended at the desired concentration with sterile PBS. $5x10^5$ bacteria (40 ul) were intranasally administered on anesthetized mice. 24 hours after infection mice were sacrificed (Figure S2A). The lungs were re-suspended in 500 ul of sterile PBS and homogenized using gentleMACS dissociator. Different dilutions of lungs were plated in agar nutrient broth. CFU numbers were counted 24 hours later (Figure S2B).

In vivo labeling of circulating CD4 T cells

To distinguish between circulating $CD4^+$ T cells and $CD4^+$ T cells infiltrating into the lung parenchyma, we injected fluorochrome labeled antibody specific for CD4 (CD4-A700) into the bloodstream of mice. Briefly, naive or immunized mice were injected intravenously with 5 μg Alexa 700 conjugated anti-CD4 Ab (clone RM4-5) in PBS, and after 7 min, mice were euthanized. For *in vitro* CD4 staining, Pacific Blue conjugated anti-CD4 Ab (clone RM4-4) was used. In all the experiments blood staining controls were used and around 96%–99% of $CD4^+$ T cells were labeled.

Lymphocyte Preparation and Flow Cytometry

Spleen, mediastinal lymph nodes (medLNs), and bone marrow (BM) were removed from immunized (day 35) or naive euthanized mice, placed into RPMI media supplemented with 5% fetal calf serum (FCS), and passed through a cell strainer (70mm).

For isolation of lung infiltrates, cells were collected after 1 hr digestion in RPMI media supplemented with 5% FCS, 1 mg/ml Collagenase D (Roche), and 10 mg/ml DNase I (Sigma) at 37 C. Homogenates were passed through a cell strainer, and ammonium- chloride-potassium lysing buffer was used. Immune cells were separated with a Percoll gradient by centrifugation at 450 g for 20 min. Cells were removed from the interface, washed and stained with the indicated FACS antibodies. Cells were acquired on an LRS II Flow Cytometer (BD Biosciences), and data were analyzed with FlowJo software (Tree Star).

For intracellular IL-17A and IFN-γ staining in Figure 4C, cells were re-stimulated for 3 hr with phorbol 12-myristate 13-acetate (20 ng/ml) and ionomycin (1 mg/ml) in the presence of monensin (1 mg/ml). Then cells were fixed with BD fixation protocol and perm for 4 min with NP-40. Cells were washed and stained with intracellular antibodies described above.

The gating strategy shown in Figure S1 was preceded by gating on the typical physical parameters of the lymphocyte (FSC, SSC), exclusion of the doublets and by gating on CD4 in-vitro$^+$ and TCRβ$^+$ cells.

The gating strategy shown in Figures 1, 4, 5,8, S2, and S5 was preceded by gating on the typical physical parameters of the lymphocyte, exclusion of the doublets and by gating on CD4 in-vitro$^+$, TCRβ$^+$, $Foxp3^{RFP\ neg}$.

In all the experiments the gating strategy of every time point was based on negative and single positive controls.

BrdU labeling

For analysis of homeostatic proliferation, Fate$^+$ mice were given BrdU (0.8 mg/ml; Sigma-Aldrich)/1% sucrose in the drinking water *ad libitum*. The water was carefully protected from light and change every other day. After 15 days, organs were collected, processed and cells were stained with surface Abs and incorporated BrdU was detected with a BrdU flow kit (BD PharMingen) according to the manufacturer's specifications.

Tamoxifen, FTY720 and Diphtheria toxin treatments

Tamoxifen (Sigma) was dissolved in corn or sesame oil (Fluka, Sigma). Naive or immunized Inducible IL17A Fate mice were i.p. injected with 2 mg of tamoxifen on day 3, 7 and 10 after immunization.

Fate$^+$ mice were immunized with heat killed Kp. 35 days later mice were given 4 μg/ml of FTY720 (Cayman Chemical Company) in the drinking water for two weeks.

For the FTY720 and infections studies, the mice were given FTY720 in the drinking water for 14 days before infection. After the infection the mice kept under FTY720 treatment for 1 more day and then sacrificed (Figure S2H)

Diphtheria toxin was administered i.p. at 50 μg/kg body weight on day 35, 37 and 39 after immunization. On day 45, mice were infected i.n. with Kp BAA-2146 and sacrificed 24 hr after infection.

Antibodies and chemicals administered to the mice

All antibodies for flow cytometry analysis were from Biolegend.

Diphteria toxin, BrdU and Tamoxifen were from Sigma.

See Key Resources Table for the details.

Immunofluorescence staining

Lungs were inflated with a perfusion buffer (1% PFA; 50% OCT; 1x PBS). Incubations at 4°C with sucrose gradients were done sequentially (10% sucrose 1 hour, 20% sucrose 1 hour, 30% sucrose 1 hour) and then the lungs were flash frozen in Tissue Freezing Medium (Jung). Cryosections (8 μm) were mounted on glass slides, fixed with 4% PFA and blocked with αCD32/CD16 (BioLegend) at a dilution of 1/200. Staining was performed for 2h at room temperature for primary antibodies and 1h at room temperature for

secondary antibodies. The following antibodies were used: rabbit anti-GFP (Life technologies) was used at 1/100, followed by polyclonal goat anti-rabbit-Alexa Fluor 488 (Life Technologies) at 1/2000 for detecting YFP. Anti-CD4-Pe (BioLegend) and anti-CD31-APC (BioLegend) were used at 1/70.

The images were captured by a confocal microscope at room temperature, using 40x and 10x lenses and were processed using Volocity 6.3 software (Perkin Elmer).

For IL7 detection in $IL7^{GFP/+}$ mice cryosections (40 μm) were mounted on glass slides, fixed with 4% PFA and blocked with αCD32/CD16 (BioLegend) at a dilution of 1/200. Staining was performed for 2h at room temperature for primary anti-GFP antibody and 1h at room temperature for secondary antibodies. The following antibodies have been used rabbit anti-GFP (Thermo/A11122), and donkey anti rabbit IgG-A488 (Thermo/A21206). The images were captured by a confocal microscope (Leica TCS SP5), using 40x and were processed using Leica LAS X software.

Real time PCR

RNA from cells was isolated using TRIzol LS reagent (Life Technology) according to the manual. RNA was subjected to reverse transcription with SuperScript II (Invitrogen) with oligo(dT) primer. cDNA was semi quantified using commercially available primer/probe sets from Applied Biosystems. Samples were analyzed with the change in cycle threshold method. Results were normalized to hypoxanthine phosphoribosyltransferase (*Hprt*).

K.pneumoniae antibody titers

Flat bottom high binding 96-well plates (Costar) were coated with 10 ug/ml of heat killed Kp in PBS at 4°C overnight, and then washed with PBS-Tween 20 0.05%. Each plate was blocked with PBS plus 1% BSA (blocking buffer) overnight at 4°C. Serum samples were diluted in blocking buffer and incubated for 2 h at room temperature. Detection of IgM or IgG was done using goat anti-mouse IgM-Biotin or anti-mouse IgG-Biotin (Southern Biotech) for 1 h at room temperature followed by incubation with streptavidin coupled to Horseradish peroxidase (Vector laboratories) for 30 minutes at room temperature. The reaction was developed with 3, 3′, 5, 5′-tetramethylbenzidine substrate-chromogen (BD Bioscience) and stopped with 1N H2SO4. Anti-Kp titers were determined by serial dilutions of plasma and the titer was defined as the highest dilution that yielded an OD at 450 nm that was 2-fold greater than the background level.

Cutaneous Candida albicans infection

C. albicans (kindly provided by J. Craft and D. Kaplan, (Yale University and University of Pittsburg respectively) was grown in YPAD medium at 30°C until the OD_{600} reached 1.5–1.8. After washing with sterile PBS, *C. albicans* were counted using a hemocytometer.

Mice were anesthetized with ketamine and xylazine (100/10 mg/kg body weight), shaved on the back with electric clipper, then chemically depilated with Nair hair remover lotion (Church & Dwight) for 3 minutes and cleaned. The stratum corneum was removed with 20 strokes with 220 grit sandpaper (3M). $2x10^8$ *C. albicans* in 50 ul of sterile PBS was applied to the skin. 30 days after infection mice were sacrificed and 1 cm^2 of infected skin was excised, minced and then digested for 1 h at 37°C in RPMI medium containing liberase (400 μg/ml; Roche) collagenase D (1 mg/ml; Roche) and DNase I (10 mg/ml Sigma) with continuous stirring. Cells were separated via a Percoll gradient by centrifugation at 450 g for 20 min. Cells were then removed from the interface, washed, stained with specifics abs and analyzed by FACS.

Bacillus Calmette-Guérin (BCG) infection

Mycobacterium bovis BCG (kindly provided by Dr Lauren Cohn, Yale School of Medicine, Pulmonary, Critical Care and Sleep Medicine) was grown in Middlebrook 7H9 broth base (Difco) supplemented with 10% Bacto Middlebrook OADC enrichment (Remel) for 2 weeks at 37°C. Mice were infected intranasaly with $1x10^6$ viable bacteria in 20ul of PBS or with PBS alone as a control. The final concentration of viable bacteria was enumerated by plate counts of CFU with Middlebrook 7H10 agar (Difco) supplemented with 0.5% glycerol (Difco) and 10% Bacto Middlebrook OADC enrichment.

After 30 days of infection mice were sacrificed, the lungs were harvested and processed as described above for the experiments with *K. pneumoniae.*

Parabiosis

In short, females were anesthetized with a mixture of Ketamine/Xylazine (100 mg/kg and 10 mg/kg respectively). After shaving the corresponding lateral aspects of each mouse, matching skin incisions were made from behind the ear to the hip and sutured together with nylon and collagen (5-0,ETHICON, VICRYL*) absorbable suture. Then these areas were clipped with 7-mm stainless-steel wound clips (Reflex7).

RNA sequencing

All cells used for bulk RNA-sequencing were obtained from mice immunized with heat-killed Kp (described above) 35 days post-immunization. Purified lymphocyte populations were obtained from lymph nodes as described above, lymphocytes populations

from lung tissue were obtained via collagenase digestion and percoll separation as described above. Purified RNA was obtained using QIAGEN Kits.

Libraries for RNA sequencing were generated using Illumina TruSeq mRNA-Seq Sample Prep Kits. Library concentration and quality was assessed using a Bioanalyzer, and sequencing performed on an Illumina HiSeq 2500 at the Yale Center for Genome Analysis.

Analysis performed using the Tuxedo suite, with splice junction mapping performed using TopHat and transcript quantification using Cufflinks (Trapnell et al., 2012). Downstream analysis was performed in R using CummeRbund (http://compbio.mit.edu/cummeRbund/) analysis software, heatmaps were produced using the package (https://cran.r-project.org/web/packages/pheatmap/pheatmap.pdf) "pheatmap" in R. Gene ontology analysis was performed using DAVID (Huang et al., 2009).

Single cell RNA sequencing

Naive or immunized (day 35) C57BL/6 mice were injected intravenously with 2.5 ug Alexa 700 conjugated anti-CD45.2 Ab in PBS, and after 7 min, mice were euthanized. For *in vitro* CD45.2 staining, PECy7 conjugated anti-CD45.2 Ab was used. For isolation of total lung cells, cells were collected after 1 hr digestion in RPMI media supplemented with 5% FCS, 1 mg/ml Collagenase D (Roche), 10 mg/ml DNase I (Sigma) and 0.1 mg/ml Dispase II (Sigma) at 37 C 250 rpm. Homogenates were passed through a cell strainer, and ammonium- chloride-potassium lysing buffer was used. After *in vitro* staining with PECy7 anti-CD45.2 and Pacific blue anti-CD4 Abs, CD45.2 *in vivo* ^{neg}, CD4 ^{neg} cells were sorted into PBS plus 0.01% BSA. The cells were diluted to concentration of 100 cells/μl and 1 mL aliquots were used as input to the Drop-seq protocol. Cells were processed for Drop-seq within ~30 min of collection.

Drop-seq was performed as described previously (Macosko et al. 2015; Shekhar et al., 2016) with minor modifications. The beads were purchased from ChemGenes Corporation, Wilmington MA (catalog number Macosko201110) and the PDMS co-flow microfluidic droplet generation device was generated by Nanoshift, Emeryville CA. The cDNA was generated using Template Switch Oligo and the populations of 5,000 beads (~150 cells) were separately amplified for 16 cycles of PCR (conditions identical to those previously described) with SMART PCR primer and PCR products were purified by the addition of 0.6x AMPure XP beads (Beckman Coulter). For each condition the cells from multiple mice were pooled together. The immunized group consisted of cells from 3 mice and naive condition consisted of 5 mice. Each sample was collected by Drop-seq. For immunized conditions two 1 mL collections were performed and for naive mouse one collection was performed. For immunized group the cDNA from an estimated 4000 cells was prepared and tagmented by Nextera XT using 1000 pg of cDNA input, and the custom primers New-P5-SMART-hybrid [3] and Nextera XT primers - N701 and N702 (Illumina). For naive group, cDNA from an estimated 2000 cells was used as input into the Nextera XT tagmentation with New-P5-SMART-hybrid oligoand N704. The concentration and the quality of libraries was measured with Qubit HS DNA assay and Agilent TapeStation Three libraries were sequenced on the Illumina NextSeq 500 using 2.0 pM in a volume of 1.3 mL HT1, and 2 mL of 0.3 μM Custom Read 1 primer (*3*) for priming of read 1. Read 1 was 20 bp; read 2 (paired end) was 60 bp.

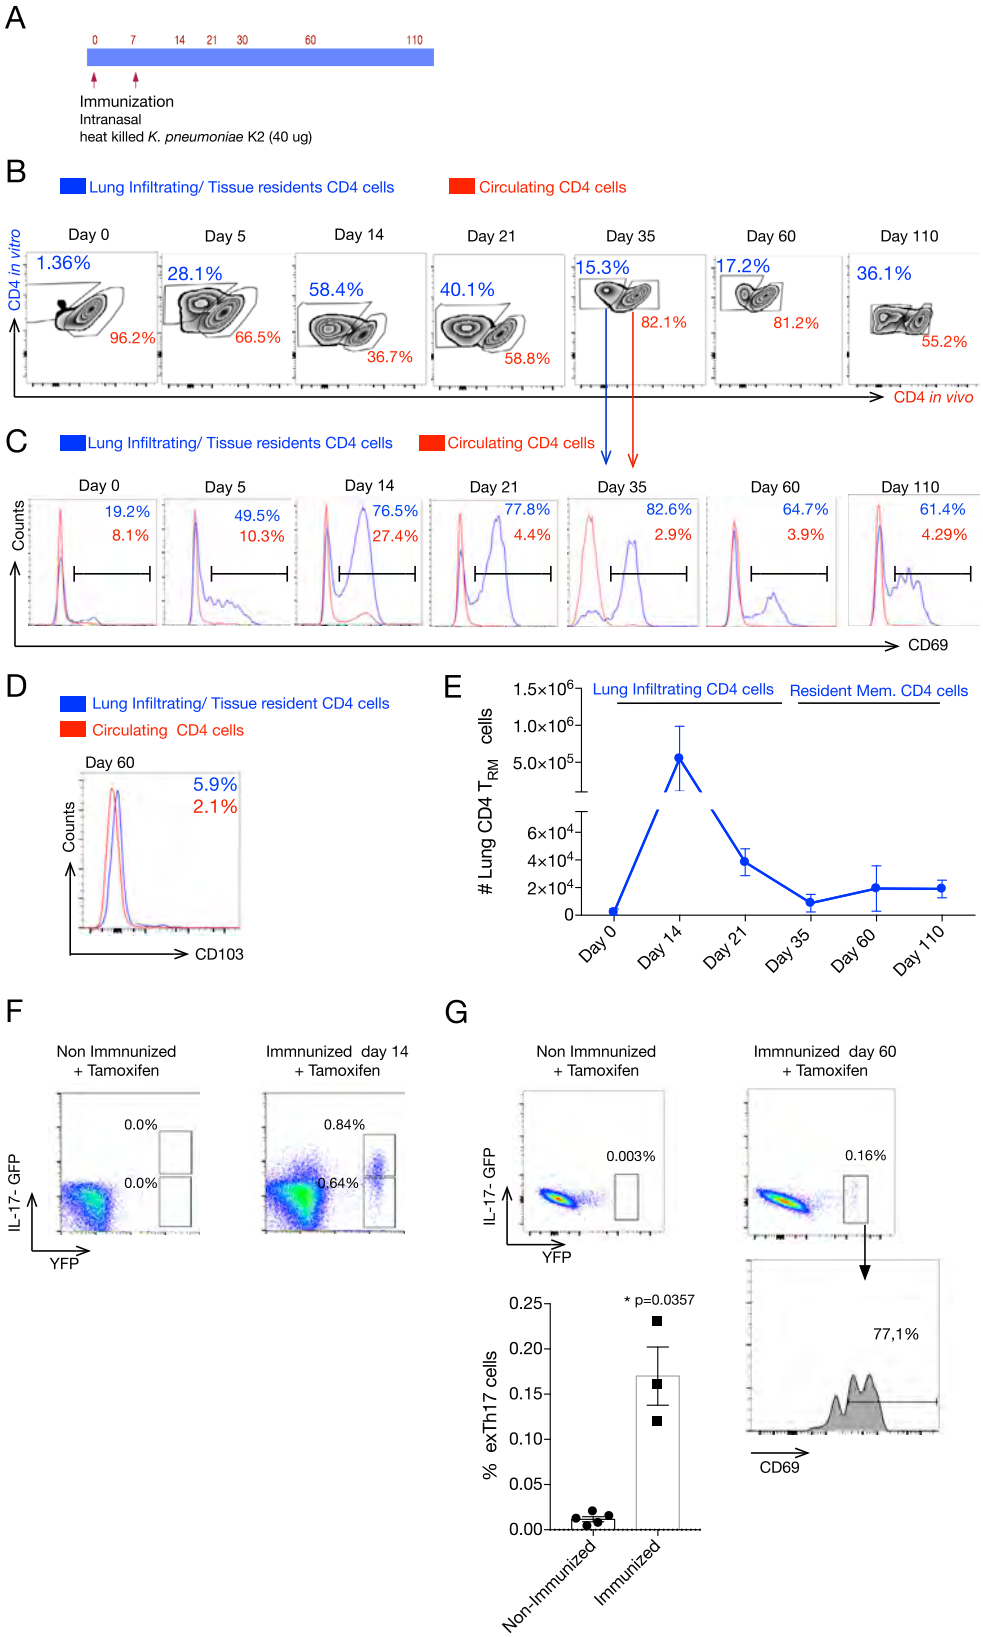
Single cell RNA-seq data was processed as described previously (Macosko et al., 2015) with Drop-seq tools. After the generation of the digital expression matrix, data was normalized in terms of log (*CPM* / 10 + 1), where *CPM* stands for counts per million (meaning that the sum of all gene-levels is equal 1,000,000). Subsequently, to visualize the cell subpopulations in two dimensions, PCA (principal component analysis) followed by t-SNE (t-Distributed Stochastic Neighbor Embedding), a non-linear dimension reduction method, were applied on the normalized data. DBSCAN (Density-based spatial clustering of applications with noise) was then used on the t-SNE coordinates to investigate cell subpopulations. Marker genes for each cluster of cells were identified based on binary classifiers trained with Logistic Regression with the R package "*glm*" (https://www.R-project.org/). In order to analyze behaviors of specific genes in different clusters and conditions (Figure 4F), fraction of cells expressing the gene of interest and average expression values among expressing cells were calculated.

CDR3 TCRβ sequencing

Spleen and lung were removed from immunized mouse. Tissue resident cells from the lung were isolated by cell sorting CD4 $^{in\ vitro+\ in\ vivo\ neg}$ (YFP^{neg}, exTh17 and Th17). Memory and naive CD4 T cells were isolated from spleen of the same mouse by cell sorting.

DNA extraction, amplification and TCRβ-chain sequencing was conducted by Adaptive Biotechnologies based on the ImmunoSEQ platform (Carlson et al., 2013)

QUANTIFICATION AND STATISTICAL ANALYSIS



Statistical Analysis

Statistical analyses were calculated in Prism 6.0 (Graphpad Software). According to the experimental set-up and the distribution of the means (normal versus non parametric) we used ANOVA or Kruskal-Wallis followed by Dunnett and Mann - Whitney U test, respectively, for the multiple comparisons; $p < 0.05$ was considered significant. Bonferroni correction was used to counteract the problem in case of multiple comparisons. The specific statistical analyses used in each figure are further described in the figure legends.

DATA AND CODE AVAILABILITY

The datasets of the RNA-Seq, single cell RNA-Seq and CDR3 TCRβ-Seq generated during this study are available at GEO: GSE130446; GEO: GSE131450 and http://clients.adaptivebiotech.com/login respectively. The accession number for RNA-seq in Fig.3 reported in this paper is GEO: GSE130446. The accession number for Single cell RNA-seq in Fig.4 reported in this paper is GEO: GSE131450. The DOI for Immuno-seq in Fig.2 reported in this paper is https://doi.org/10.21417/MCAV2019CELL. For further details see the Key Resources Table.

Supplemental Figures

(legend on next page)

Figure S1. Related to Figure 1

(**A**) Scheme of immunization with heat killed *Klebsiella pneumoniae* (serotype K2) on day 0 and 7. At different time points C57BL/6 mice were sacrificed and the presence of CD4 T_{RM} was evaluated using an *in vivo* antibody labeling technique. (**B**) Zebra plots show accumulation of infiltrating/tissue resident CD4 *in vitro*$^{+}$ TCR-β^{+}, CD4 *in vivo*^{neg}, Foxp3 ^{neg} T cells in lung after immunization with heat killed *K. pneumoniae* in C57BL/6 mice at different time points. *In vivo* labeling delineates infiltrating/resident (CD4 *in vivo*^{neg}, CD4 *in vitro*$^{+}$) and circulating (CD4 *in vivo*$^{+}$, CD4 *in vitro*$^{+}$) polyclonal lung CD4 T cell subsets. (**C**) CD69 and (**D**) CD103 expression in infiltrating/ T_{RM} (blue line) and circulatory (red line) CD4^{+} TCR β^{+} T cells. (**E**) Absolute number of lung CD4 infiltrating/resident (CD4 *in vitro*$^{+}$, CD4 *in vivo*^{neg}, TCRb^{+}) T cells at different time points after immunization (n = 3 per time point). One out of 2 independent experiments is shown. (**F**) The dot plots show the frequency of lung exT_H17 cells in non-immunized (left) and day 14 immunized inducible IL17A Fate mice (right). Both groups of mice were treated with tamoxifen. (**G**) The dot plots show the frequency of lung exT_H17 cells in non-immunized (left) and day 60 immunized inducible IL17A Fate^{+} mice (right). Both groups of mice were treated with tamoxifen. The bottom histogram shows the expression of CD69 in exT_H17 cells of immunized + tamoxifen mouse. The bar graphs on the right show the frequency of exT_H17 cells in the lung of non-immunized and immunized mice (Day 60). Each dot represents one mouse. Representative dot plots are shown (n: 3 mice per group). One out of 3 experiments is shown. Data are represented as mean ± SEM. Mann-Whitney U test, *p = 0.0357

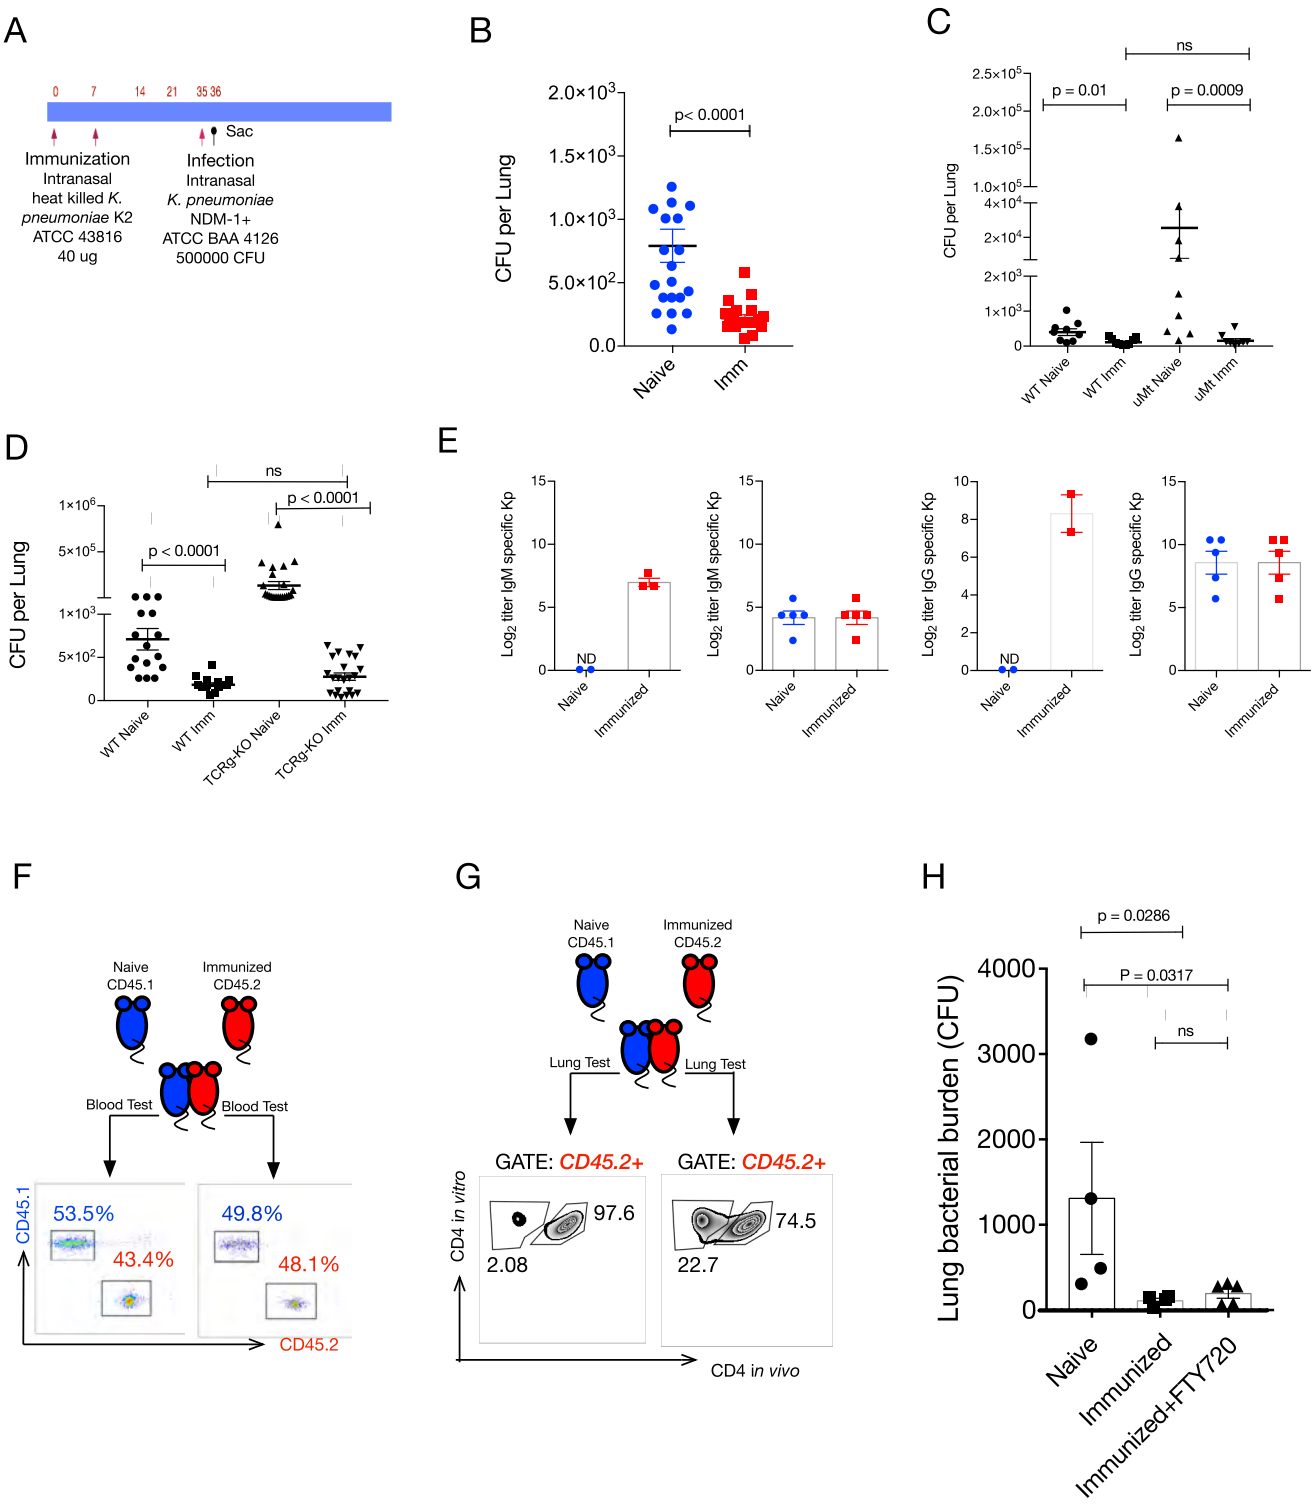


Figure S2. Related to Figure 1

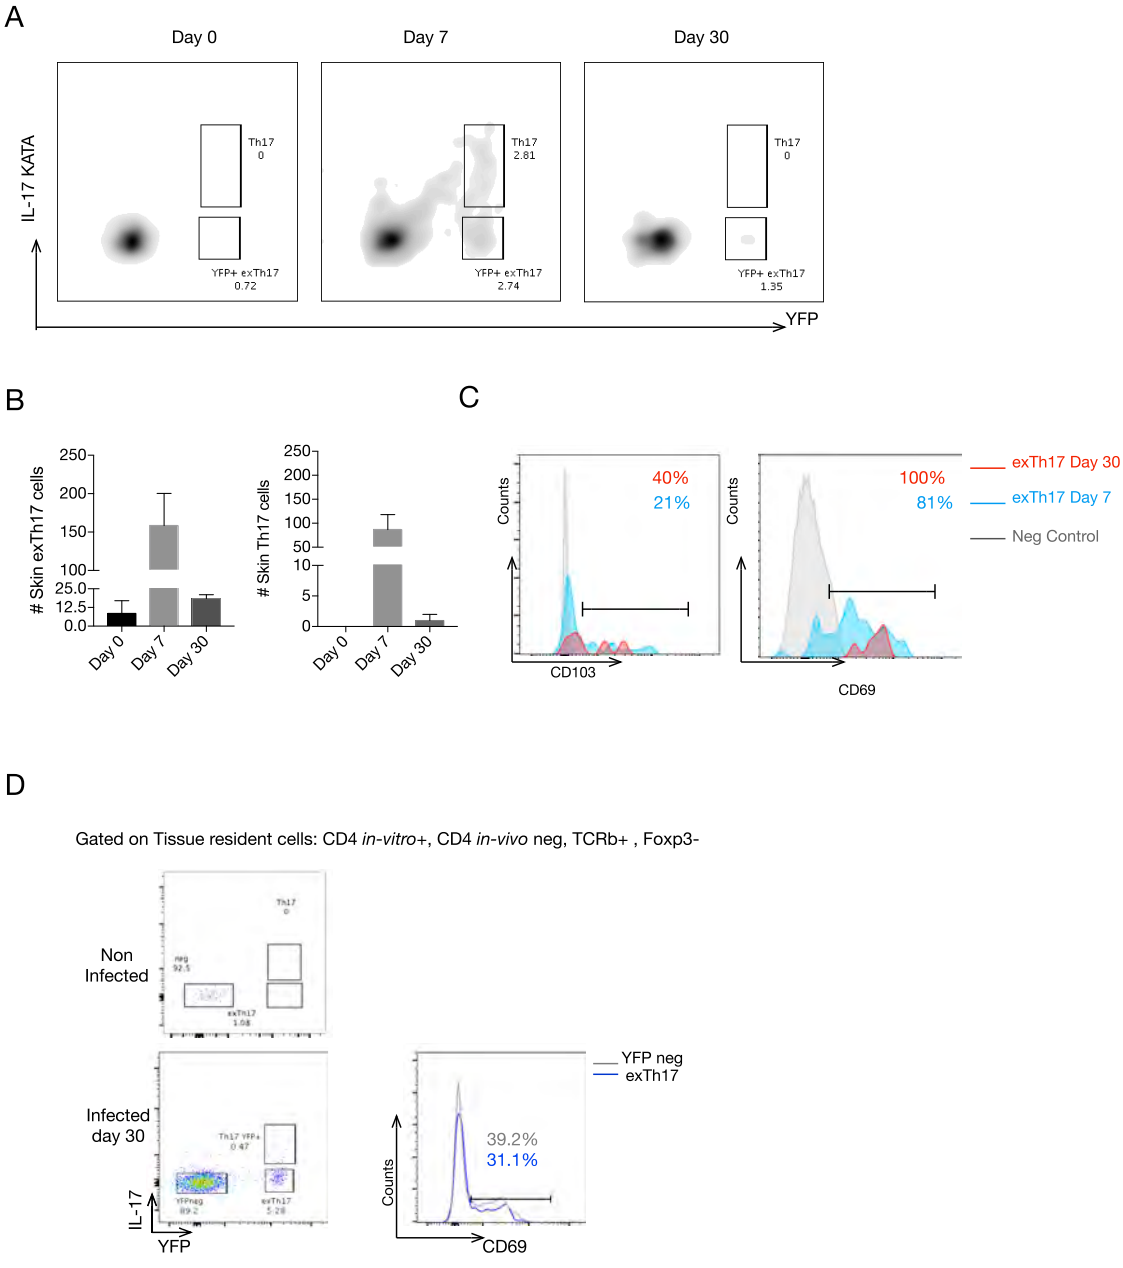
A) Scheme of immunization with heat killed *Klebsiella pneumoniae* (K2 serotype) on day 0 and 7 and infection with Cre (carbapenem-resistant enterobacteriaceae) Kp (NDMI$^+$) on day 35. 24 hours later the mice where sacrificed. (**B**) The graphs show the amount of Cre Kp (NDMI$^+$) CFU after 24 hs of infection of C57BL/6 WT naive mice (blue circles) or immunized mice (red squares). **C and D)** The graphs show the amount of Cre Kp (NDMI$^+$) CFU after 24 hs of infection. WT, uMT and TCR$\gamma\delta$ KO mice were immunized at day 0 and 7 with heat killed Kp serotype 2 (ATCC 43816) and on day 35 infected with live 5x10^5 CFU of Cre Kp (NDMI$^+$ ATCC BAA 2146). Each dot represents one mouse. Data is cumulative of 4 experiments for C, and 2 experiments in D. (**E**) The graphs show the titer of specific antibodies

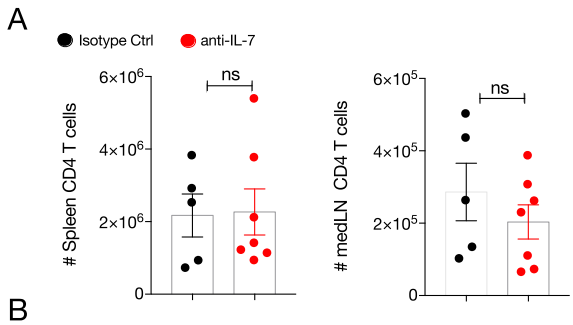
(legend continued on next page)

against Kp, IgM and IgG before parabiosis in naive and day 30 immunized mice. 30 days after parabiosis the titer of specific antibodies against Kp, IgM and IgG were measure in naive and immunized mice. (**F**) Naive CD45.1^{+} and day 35 immunized CD45.2^{+} mice were surgically joined for 3 weeks. Before sacrifice anti CD4 antibody was injected to distinguish tissue infiltrating/resident and circulating cells. Dot plots showing blood full chimerism 3 weeks after surgery. (**G**) Dot plots showing the percentage of CD4^{+} CD45.2^{+} cells in the lung of naive CD45.1 mouse (left) and in the lung of immunized CD45.2 mouse (right). (**H**) The graphs show the amount of Cre Kp (NDMI^{+}) CFU after 24 hs of infection. Immunized mice were given FTY720 in the drinking water from day 35 until the day of sacrificed (14 days) (Immunized + FTY720). Naive and Immunized mice drinking normal water were also infected and used as controls.

Data are represented as mean ± SEM and ± SD.

Mann-Whitney U test (B), Kruskal-Wallis ($p = 0.0004$) and post hoc Mann-Whitney U test with Bonferroni correction (C), Kruskal-Wallis ($p < 0.0001$) and post hoc Mann- Whitney U test with Bonferroni correction (D). Kruskal-Wallis ($p = 0.0134$) and post hoc Mann Whitney U test with Bonferroni correction (H).





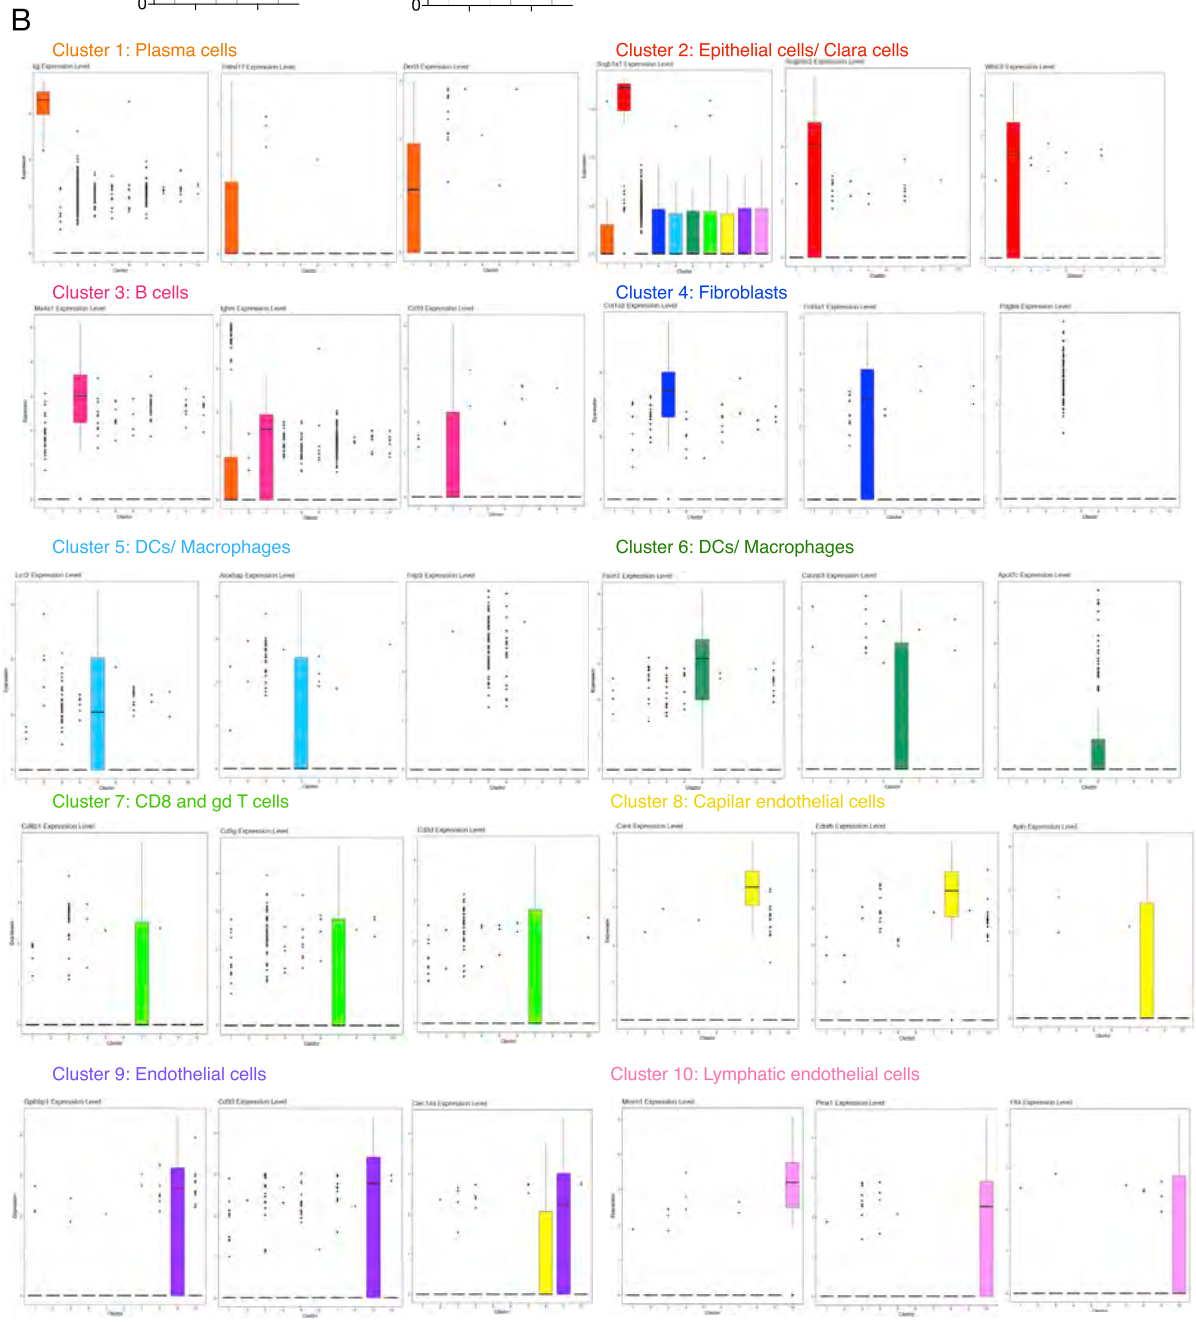


Figure S3. Related to Figure 1

Fate^{+} mice where infected in the skin with *C. albicans*. **A, B)** Dot plots show the percentage and (**B**) absolute numbers of Th17 and exTh17 after infection at day 7 and day 30. Non infected Fate^{+} mice where used as controls (day 0). (**C**) Histograms show the percentage of skin exTh17 cells that express CD103 (left graph) and CD69 (right graph) at day 7 (blue histogram) and day 30 (red histogram) after infection. Grey histograms represent negative control. (**D**) Dot plots show the frequency of T_{RM} exT_H17 cells in the lung of naive (top) or BCG infected Fate^{+} mice after 30 days of infection (bottom). The histogram shows the expression of CD69 in lung exT_H17 cells (blue line) and YFP negative cells (gray line). Representative dot plots are shown (n:3 mice per group).

(legend on next page)

Figure S4. Related to Figure 4

(**A**) Fate+ immunized mice were intra-nasally treated with anti-IL-7 Ab, or with an isotope control on day 35, 37 and 39 after immunization and the mice were sacrificed on day 40. The graph shows the absolute number of spleen (left) and dLN (right) exT_H17 cells in the isotype ctrl treated group (black circles) and in the anti-IL-7 treated group (red circles). Each dot represents one mouse. Two combined experiments are shown. Data are represented as mean ± SEM. Mann-Whitney U Test ns (non-significant). (**B**) The Boxplots show the specific genes for each cluster, with cluster labels on the x axis; normalized expression values on the y axis. The same color codes as in Figure 4F were used. Three markers are shown for each cluster.

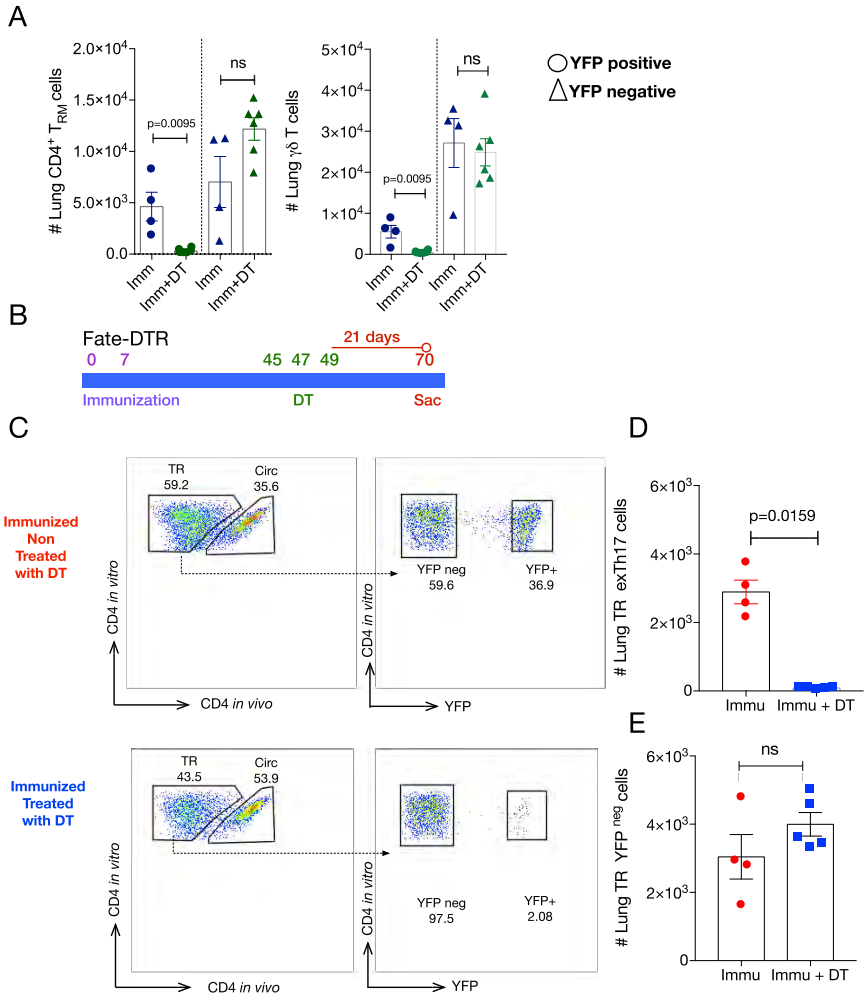

Figure S5. Related to Figure 5

Immunized Fate-DTR mice were either treated (Tx) with diphtheria toxin (DT) (Figure 5E) or with PBS and were sacrificed 7 days after the last DT treatment. (**A**) Absolute number of Lung T_{RM} cells (CD4 *in vitro*$^{+}$, CD4 *in vivo*^{neg} TCRβ^{+}, FoxP3^{neg}) and $\gamma\delta$T cells. The circles and triangles represent YFP positive (exT_H17, ex$\gamma\delta$IL17) and YFP negative cells respectively. Blue symbols and green symbols represent immunized PBS Tx or immunized DT Tx mice respectively. Each symbol represents one mouse (Immu n = 4; Imm+DT n = 6). Showing one out of 2 representative experiments. Data are represented as mean ± SEM. Mann-Whitney U test, ns (non-significant). (**B**) Immunized Fate-DTR mice were either treated (Tx) with diphtheria toxin (DT) on Day 45, 47 and 49 or with PBS and were sacrificed 21 days after the last DT treatment. (**C**) Representative dot plots showing the percentage of YFP negative and YFP positive cells (Gate CD4 *in vitro*$^{+}$, CD4 *in vivo*^{neg} TCRβ^{+}, FoxP3^{neg}) (Imm = 4; Imm+DT n = 5). Each dot plot represents one mouse. (**D**) Absolute number of YFP^{+} (exT_H17) Lung T_{RM} cells. Data are represented as mean ± SEM. Mann- Whitney U test. (**E**) Absolute number of YFP^{neg} Lung T_{RM} cells. Data are represented as mean ± SEM. Mann- Whitney U test, ns (non-significant).

Keywords: 6-OHDA, L-DOPA, microcircuit analysis, *Mus Musculus*, Parkinson's disease, striatum

Abstract

Previously, we have shown that chemical excitatory drives such as *N*-methyl-D-aspartate (NMDA) are capable of activating the striatal microcircuit exhibiting neuronal ensembles that alternate their activity producing temporal sequences. One aim of this work was to demonstrate whether similar activity could be evoked by delivering cortical stimulation. Dynamic calcium imaging allowed us to follow the activity of dozens of neurons with single-cell resolution in *mus musculus* brain slices. A train of electrical stimuli in the cortex evoked network activity similar to the one induced by bath application of NMDA. Previously, we have also shown that the dopamine-depleted striatal microcircuit increases its spontaneous activity generating dominant recurrent ensembles that interrupt the temporal sequences found in control microcircuits. This activity correlates with parkinsonian pathological activity. Several cortical stimulation protocols such as transcranial magnetic stimulation reduce motor signs of Parkinsonism. Here, we show that cortical stimulation *in vitro* temporarily eliminates the pathological activity from the dopamine-depleted striatal microcircuit by turning off some neurons that sustain this activity and recruiting new ones that allow transitions between network states, similar to the control circuit. When cortical stimulation is given in the presence of L-DOPA, parkinsonian activity is eliminated during the whole recording period. The present experimental evidence suggests that cortical stimulation such as that generated by transcranial magnetic stimulation, or otherwise, may allow reduce L-DOPA dosage.

Introduction

Parkinson's disease (PD) is a movement disorder characterized by bradykinesia, rigidity, resting tremor and postural, locomotor and cognitive deficits (Dauer & Przedborski, 2003; Thomas & Beal, 2010; Kalia & Lang, 2015). These signs and symptoms appear as a result of dopamine depletion in the basal ganglia following dopaminergic cell loss in the substantia nigra pars compacta (SNc; Ehringer & Hornykiewicz, 1960; Andén *et al.*, 1964; Bernheimer *et al.*, 1973). Striatal neurons receive monosynaptic glutamatergic connections from the cortex and thalamus (Kemp & Powell, 1971; Bernard *et al.*, 1997; Bernard & Bolam, 1998; Bolam *et al.*, 2000; Gerfen & Surmeier, 2011; Arias-García *et al.*, 2017). These connections have proven to be important in action selection, habits and goal-directed behavior (Znamenskiy & Zador, 2013). Deficiencies in *N*-methyl-D-aspartate (NMDA) receptors affect action selection, learning, procedural memory, habits, coordination and storage of motor commands (Beutler *et al.*, 2011; Lambot *et al.*, 2016).

In dopamine-depleted animal models, alterations in the synaptic integration of corticostriatal commands have been reported, such as differences in neuronal excitability (Fieblinger *et al.*, 2014), distinct corticostriatal synaptic integration (Flores-Barrera *et al.*, 2011), changes in NMDA receptor subunits (Feng *et al.*, 2014), altered responses to somatosensory inputs (Ketzef *et al.*, 2017) and changes in long-term plasticity (Picconi *et al.*, 2012). Cortical stimulation by several means temporarily improves the parkinsonian state (e.g., Dileone *et al.*, 2017), leading some researchers think that the cortex is a main player in the disease (Arbuthnott & Garcia-Munoz, 2016; Pérez-Ortega *et al.*, 2016).

Previous reports have described microcircuit behavior of the striatal network in control (using NMDA as excitatory drive) and parkinsonian conditions (Carrillo-Reid *et al.*, 2008; Jáidar *et al.*, 2010; Pérez-Ortega *et al.*, 2016). Microcircuit alterations are reversed by L-DOPA administration (Plata *et al.*, 2013a) as *in vivo* conditions (Ketzef *et al.*, 2017). However, there is no experimental work in animal models that observes whether cortical stimuli may change the striatal microcircuit activity during the parkinsonian

state. Therefore, the aims of this work were, first, to evoke prolonged microcircuit activity without using chemical stimulation such as bath application of NMDA and second, to characterize the alteration of microcircuit activity due to cortical stimulation in dopamine-depleted (DA-depleted) striatal circuitry after unilateral 6-OHDA lesions, a commonly used hemiparkinsonian model in rodents. Finally, we report the mechanisms by which cortical stimulation alone, or together with L-DOPA administration, acts to improve parkinsonian pathological activity at the microcircuit level.

Materials and methods

Animal use and care

All experiments were carried out in accordance with the international guidelines for the ethical use of experimental animals established in the NIH guidelines, and detailed protocols were submitted and approved by the Institutional Committee for Laboratory Animals Care and Use of the Instituto de Fisiología Celular (IFC), UNAM (NOM-062-Z00-1999; project protocol JBD-59-15). Experiments were performed in male C57BL/6 mice breaded in the animal facilities of the IFC. Mice were housed in a temperature-controlled, pathogen-free room, on a 12 : 12 light: dark cycle and allowed food and water *ad libitum*. P21-P23 mice were used for stereotaxic surgery. P29-P40 brain slices were prepared for calcium imaging experiments. Slices from at least four to seven different animals were used in each experimental sample (control $n = 5$ slices, hemiparkinsonian $n = 7$ slices and hemiparkinsonian + L-DOPA *in vitro*, $n = 4$ slices). In both surgical and perfusion protocols, animals were anesthetized with ketamine (85 mg/kg)–xylazine (15 mg/kg) and all measures were taken to minimize pain and discomfort trough every protocol. Body temperature was modulated peri- and post-operatively until full recovery. Mice were killed by decapitation, and the brains were rapidly dissected and processed. To prevent bias, mice from each litter were randomly chosen for surgery. DA-depleted animals were randomly used for either DA-depleted or DA-depleted + L-DOPA experiments. A total of six animals were used to complete the control group experiments, four intact and two sham. To perform the DA-depleted experimental groups, 22 mice were used to perform the surgical procedure described below. Nineteen mice met the DA-depleted selection criteria, and these were used for slice preparation.

6-OHDA model

Mice P21-P23 were administered intra-peritoneal ketamine (85 mg/kg)–xylazine (15 mg/kg) and placed under a stereotaxic instrument. Once the skull was cleared and the coordinates located, 0.6 μL of 6-OHDA (0.1 mg/mL) was injected at a 0.2 μL/min rate in −2.6 mm AP, −1.5 mm LM and −4.7 mm DV from bregma. Coordinates were previously optimized in the laboratory for better accuracy. The whole procedure was also performed in *sham* mice, except that saline solution (NaCl 0.9%) without 6-OHDA was used. Body temperature was modulated peri- and post-operatively until full recovery. Caution was taken to minimize animal pain and discomfort through all the procedures.

Post-operatively mice were allowed to recover for 7 days in the vivarium in a temperature-controlled, pathogen-free room, on a 12 : 12 light: dark cycle and allowed food and water *ad libitum*.

After full recovery, lesion was confirmed by the apomorphine-induced turning behavior test (Ungerstedt & Arbuthnott, 1970). Mice were placed in rotameter bowls and were allowed to acclimatize for 5 min. Spontaneous rotations were measured for at least 30 min by the program RotaCount 2.0. After that time, mice received a subcutaneous injection of apomorphine hydrochloride (0.05 mg/kg) in vehicle (normal saline with 0.02% ascorbate). Rotations were measured for 60 min. Clockwise (CW) and counterclockwise (CCW) rotations were contrasted between and within spontaneous/ apomorphine conditions. Mice CW/CCW ratio was inverted between spontaneous and apomorphine conditions. Monitored for 60 min, mice showing > 80% of contralateral turning unbalance (contralateral/total rotations) were considered for further experiments. To minimize the effects of dopamine receptor priming, experiments were performed at least 10 days after the evaluation (Morelli *et al.*, 1989).

Slice preparation

Mice P29-P40 were anesthetized intra-peritoneally with ketamine (85 mg/kg)–xylazine (15 mg/kg) and perfused intracardially with chilled sucrose solution (sucrose 234 mM, $NaHCO_3$ 28 mM, dextrose 7 mM, pyruvate 4.54 mM, ascorbic acid 0.28 mM, KCl 2.5 mM, $MgCl_2$ 7 mM, NaH_2PO_4 1.44 mM, $CaCl_2$ 0.4 mM, 4 °C). Mice were rapidly decapitated and brains extracted. A total of 250-μm-thick horizontal slices with a 30° angle were taken in a vibratome (PELCO easiSlicer Ted Pella, Redding, CA, USA). For the rest of the procedures, the slices were maintained in artificial cerebrospinal fluid (NaCl 126 mM, dextrose 15 mM, $NaHCO_3$ 26 mM, thiourea 0.2 mM, ascorbic acid 0.2 mM, KCl 2.5 mM, $MgCl_2$ 1.3 mM, NaH_2PO_4 1.2 mM and $CaCl_2$ 2 mM; pH = 7.4; 300 ± 5 mOsm/L) and continually perfused with 95% O_2 and 5% CO_2. The procedure was identically performed for both control and DA-depleted animals, except that only the right hemisphere was taken in DA-depleted animals, while both hemispheres from control animals were used.

Data acquisition

Slices were incubated for a 40-min period at 37 °C in a Calcium Orange solution (Calcium Orange 8.2 μM, 0.1% DMSO, 0.67% Pluronic Acid in ACSF). Calcium Orange was chosen for this set of experiments because long-term data acquisition is required and Calcium Orange has very low photobleaching (Thomas *et al.*, 2000). Later, slices were placed in a perfusion chamber with constant ACSF flow under a 20× immersion objective (N20X-PFH—20× Olympus XLUMPLFLN Objective, 1.00 NA, 2.0 mm WD, Center Valley, PA, USA). Observation field was 750 × 750 μm. A Lambda LS Illuminator (Sutter Instruments, Petaluma, CA, USA) and a 570/30-nm light filter were used for fluorophore stimulation and signal acquisition. Fluorescence videos were recorded using a CoolSnap K4 camera (Photometrics, Tucson, AZ, USA) controlled trough Im-Patch ©, an open-access software designed in the LabView environment (http://www.im-patch.com), taking 4–6 frames/s and 720–2160 frames per video. Each experiment consisted of 7–10 videos accounting for up to 60 min per experiment. Three slice conditions were used: control (Ctrl), dopamine-depleted (DA-depleted) and DA-depleted +L-DOPA. In all of them, spontaneous activity was recorded before and after the administration of a single stimulation train (CtxS = 10 pulses, 40 Hz, 1.1–1.3 mA) using a bipolar concentric electrode (FHC, #CBCFE75, Bowdoin, ME, USA) inserted in cortex layer V. When required, 10 μM L-DOPA was added to superfusion bath prior to stimulation and maintained until the end of the experiment. A 0.5 mM KCl solution was administered at the end of each experiment to count all viable cells during the experiment. Only slices in which 85% of the cells participating in the experiment were still viable were taken into account.

Data analyses

Videos were processed with Im-Patch ©. Using this software, single cells were identified. Calcium entry into the cell (Ca^{2+} signals or transients) and its time derivative were calculated for each cell along time and during the whole experiment. Using time derivatives of Ca^{2+} transients, moments of neuronal electrical activity were inferred as previously reported (Carrillo-Reid *et al.*, 2008, 2009, 2011, 2015; Jáidar *et al.*, 2010; López-Huerta *et al.*, 2013; Plata *et al.*, 2013a,b; Hernandez-Flores *et al.*, 2015; Pérez-Ramírez *et al.*, 2015; Pérez-Ortega *et al.*, 2016). Frames whose time derivative exceeded two standard deviations from the noise or basal activity were considered as active frames due to neuronal ensembles. Frame activity was transferred into an activity matrix where 1 denotes an active and 0 a not active frame for each cell. Whole experiments are contained in these matrices and expressed as raster plots, where each row shows the activity of a single cell and each dot a frame in which that cell was active. Matrices together with their coordinates were processed to determine statistically significant coactivity peaks. The activity of all the cells in every frame was added to build a coactivity histogram. To determine significant coactivity peaks, Monte Carlo simulations were used (see Pérez-Ortega *et al.*, 2016). Briefly, the activity of every cell was shuffled over time and new randomized coactivity histograms were obtained (1000 iterations); the randomized histograms were compared to the original one, by counting the frames with a given number of coactive cells (from 0 to the number of cells). The threshold to consider significant activity peaks is established at the minimal value in which the experimental data showed greater occurrence of coactive cell events than 95% of the randomized data. The significant activity peaks were built from the frames in which the threshold was overcome and a 12- to 18-frame time bin was used. Coactivity peaks were compared based on a similarity index calculated as the cosine of the angle between vectors obtained with the dot product of each pair of vectors with significant activity normalized by their magnitude (Carrillo-Reid *et al.*, 2008) retrieving a similarity matrix. Peaks were grouped using hierarchical clustering analysis to determine neuronal ensembles or network states shown with different colors or tones in raster plots as previously reported (Pérez-Ortega *et al.*, 2016). To compare individual cell activity through different sections of the experiment, activity of each cell was determined simply as the total number of active frames/total number of frames.

To quantify the amount of activity per experiment, a cumulative activity plot was built; the value of the coactivity histogram per frame was added over time during the experiment. To compare the activity of multiple experiments, a linear fit was approximated to cumulative activity plots. Slopes of fitted lines represent the cumulative activity/time over the course of the experiment. This value was used to compare different experiments and experimental conditions. To quantify the significant activity peaks/min, the number of frames in which the coactivity histogram value was greater than the threshold determined by the Monte Carlo method was divided by the total length of the experiment in minutes. To compare the cellular activity among different experimental conditions, a cumulative distribution function was made with the cellular activity of all the active cells in all of the experiments per section, namely control (Ctrl), control plus cortical stimulation (Ctrl + CtxS), DA-depleted, DA-depleted + CtxS, DA-depleted + L-DOPA and DA-depleted + L-DOPA + CtxS.

For neurons that belong to different groups, their cellular activity on each fragment of the experiment was determined as described above. To consider an activity increase or decrease, a 20% activity change was necessary, otherwise the neuron was considered with constant activity. The parkinsonian state is characterized by a dominant more recurrent state interrupting ensembles sequences (Jáidar *et al.*, 2010; Pérez-Ortega *et al.*, 2016). To detect the appearance of these pathological network states across a sample of experiments, we calculated a recurrence index for every state with respect to the other states in each condition. The recurrence index is the relative proportion of recurrence of any state:

$$R_{\text{Index}} = \frac{R_i}{\sum \mathrm{R}_{n \neq i}}$$

where R_i is the recurrence of a given state; the appearance of the state has values 1 (one appearance) to p, where p is the number of times in which the state appeared repeatedly without alternation. This number was divided by the sum of recurrences of the other states in the experiment. In the case some network states have an excess of recurrence (dominant pathological states) circuits will be divided into two populations of network states those with high and those with low recurrence and the variance of that sample will reflect this sampling separation. In the cases where there is no predominance of any network state, all of them would have a similar recurrence index and sample variance would be smaller. In this way, we could compare all different states through sampling different experiments using neuronal ensembles no matter the duration of the particular conditions. In this case, recurrence of network states of compared samples used the O'Brien Homogeneity of Variance test.

Statistical analysis

To determine the significance threshold for coactivity peaks, Monte Carlo simulations were used; this test was programmed into a MATLAB script (MATLAB R2015a; The MathWorks, Inc. Natick, MA, USA). GraphPad Prism (GraphPad Software, Inc. La Jolla, CA, USA) was used to compare the different activity metrics among the four groups: Ctrl, DA-depleted, Ctrl + CtxS and DA-Depleted + CtxS. Tests used and their purposes are indicated as follows: multiple comparison Kruskal–Wallis ANOVA test with the *post hoc* Dunn test for pairwise comparisons, paired Wilcoxon *t*-test with a one-tail Spearman approximation to compare the activity of the same sample from one condition to another, the contingency pie chart test to compare the proportion of activity from each cellular population, the Friedman ANOVA test with *post hoc* Dunn test to compare the activity of individual cells in experiments with three different treatments, Kolmogorov–Smirnov tests to compare distributions of data sets (MATLAB) and O'Brien Homogeneity of Variance test to compare the recurrence index in the different conditions (MATLAB). Note that samples with dominant states have their variance increased.

Suppliers & reagents

The reagents used were as follows: Calcium Orange (Molecular Probes®, Life technologies, Mexico City, Mexico); pluronic acid (pluronic TM F-127, P3000MP; Life Technologies Corporation, OR, USA); 6-OHDA (6-hydroxydopamine hydrochloride; Sigma-Aldrich H4381-100MG); L-DOPA (3,4-dihydroxy-L-phenylalanine, Sigma-Aldrich D9628); and apomorphine (R-(-)-apomorphine hydrochloride hemihydrate Sigma-Aldrich A4393-250MG).

Results

Cortical stimulation in brain slices

The spontaneous cellular activity in the dorsal striatum was recorded for several minutes (Ctrl; Fig. 1A). A single train of 10 pulses at

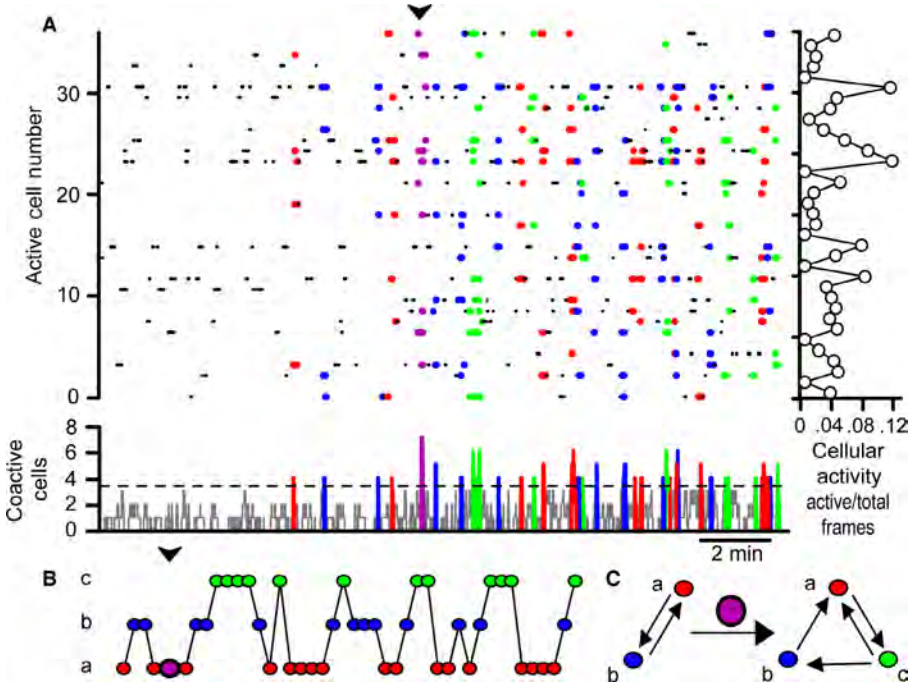

FIG. 1. Cortical stimulation activates the striatal microcircuit. (A) Raster plot of a cortical stimulation (CtxS) protocol. The moment of stimulation is shown with an arrowhead on top. Each row represents the activity of a single cell over time. Colored dots represent cells that activate together significantly. At the bottom, a coactivity histogram with the sum of active neurons per frame is shown. The dotted line shows the threshold for significant coactivity peaks ($P < 0.05$, after Monte Carlo simulations). Significant activity peaks were classified as neuronal ensembles using hierarchical cluster analyses. Different ensembles are shown in the histogram and raster plot with different tones and thicker lines. The right histogram represents individual cellular activity: the sum of the active frames divided by the total number of frames. (B) Once ensembles were identified, each dot in the sequence graph represents its activation: ensembles time sequence. Note network states that alternate their activity (a–c: bottom, middle and top). The stimulus is represented by the larger (purple) dot with an arrowhead at the top. (C) Transitions summary: before the stimulus, only two ensembles were significant and rarely active. After the stimulus, there were three ensembles that activate more frequently showing transitions between them.

40 Hz in motor cortex layer V or in cortical afferents (CtxS; Fig. 1A arrowhead) could activate the striatal microcircuit revealing continuous sequences of significant peaks of neuronal coactivity for at least 30 min. In this way the evoked activity of dozens of neurons was observed simultaneously, using calcium imaging with single-cell resolution in horizontal mouse brain slices without adding any drugs to the preparation (cf. Carrillo-Reid *et al.*, 2008). A raster plot of this activity is shown in Fig. 1A following such stimulus; each row represents the activity of a single neuron. At the bottom, a histogram of the summed activity along time shows significant peaks of coactivity where the dashed line represents the significance threshold determined with Monte Carlo simulations ($P < 0.05$). Significant coactivity peaks are marked in the raster plot and bottom histogram with thicker (or colored) dots or lines. In the plot to the right, individual cellular activity over the course of the experiment measured as the sum of activity per cell divided by the number of frames is illustrated. The moment of CtxS evokes a significant activity peak which is composed by stimulated neurons and is different to the spontaneous peaks of coactivity that follow. The significant coactivity peaks were grouped according to their similarity (see Methods) and classified, using hierarchical cluster analysis, as neuronal ensembles (raster plot) or network states (temporal sequences). The temporal sequence of ensembles activation is shown in Fig. 1B. Clearly, CtxS activates the microcircuit increasing the number of spontaneously active ensembles ($n = 5$ slices from different animals). The time sequence is summarized into network states transition cycles before and after CtxS (Fig. 1C). Note a change in the number of active ensembles after CtxS, thus generating reverberating microcircuit dynamics (Carrillo-Reid *et al.*, 2008).

In the DA-depleted striatum, there is an excess of neuronal activity as compared to the non-stimulated control striatum (Jáidar *et al.*, 2010; Plata *et al.*, 2013a,b; Pérez-Ortega *et al.*, 2016).This can be observed in the raster plot and coactivity histogram in Fig. 2 before CtxS is given. This hyperactivity is characterized by the excessive recurrence of one of the network states (Jáidar *et al.*, 2010; Pérez-Ortega *et al.*, 2016). After CtxS, alternations between network states become more balanced and transitions are recovered; this new dynamics is maintained for several minutes after stimulation (Fig. 2A; CtxS is marked with an arrowhead). Time sequence of ensembles activation (Fig. 2B) shows that before CtxS, there are several coactivity peaks with one of them exhibiting high recurrence (state 'c' at top), as though the microcircuit is trapped in state 'c'. As a consequence, transitions cycles per 3 min are commonly open (Fig. 2C left). After CtxS transitions, cycles became closed (Fig. 2C right; Pérez-Ortega *et al.*, 2016).

To compare global activity in the striatal microcircuit under different treatments, we analyzed cumulative activity (summed activity of coactive cells over time; from histograms at the bottom in Figs 1A and 2A) taking all the cells from each experiment. Solid lines in Fig. 3A illustrate cumulative activity in a representative experiment. Straight lines were fitted to experimental data (dashed). The non-stimulated striatal microcircuit (Ctrl) shows the lowest spontaneous activity along time. Significant higher activity appears after cortical stimulation (CtxS) in control conditions ($n = 5$; Wilcoxon *t*-test; $P < 0.01$), and the DA-depleted striatal microcircuit was confirmed to have higher spontaneous activity than the non-stimulated control (Fig. 3B; slopes of fitted straight lines were used to show box plots of samples distributions; $P < 0.05$; $n = 7$; Kruskal–

INFORME DE LABORES 2019

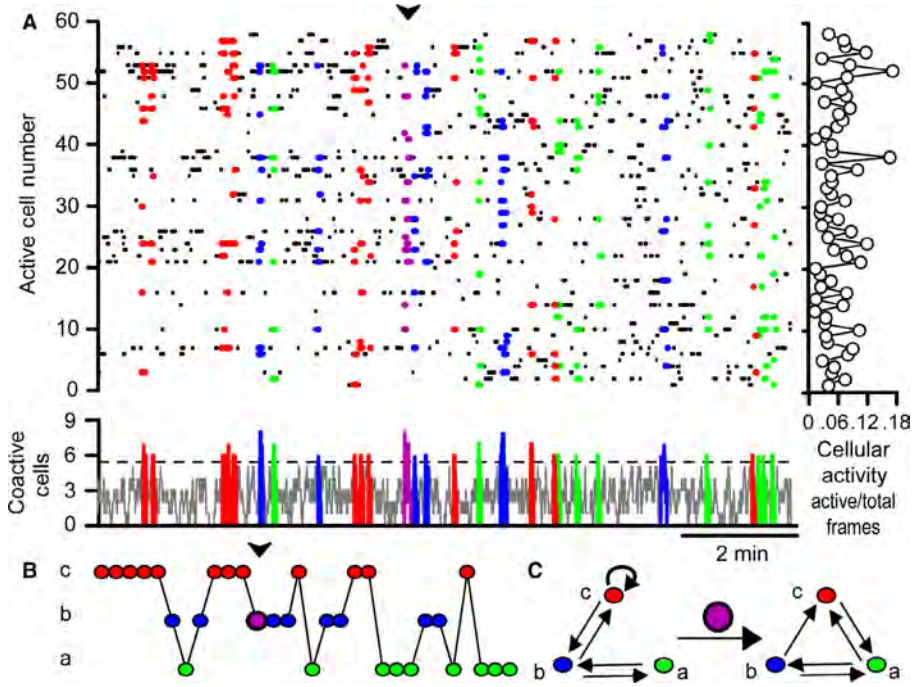

FIG. 2. Cortical stimulation modifies network state transitions in the DA-depleted striatal microcircuit. (A) Raster plot of a DA-depleted slice microcircuit before and after CtxS. Stimulation is signaled with an arrowhead on top. Each row represents the activity of a single neuron over time. Coactivity histogram is at the bottom with the sum of active neurons per frame. The dotted line shows the threshold for significant activity peaks. The significant activity peaks were classified into neuronal ensembles after hierarchical clustering. Different ensembles are shown in the histogram and raster plot with different tones (or colors) and thicker dots and lines. Individual cellular activity, the sum of all the active frames divided by the total number of frames, is at right. (B) Time sequence of ensembles activation showing significant peaks of coactivity represented by circles. The position and letters represent the ensembles to which they belong, a–c (bottom, middle and top). The stimulation is signaled by a larger circle with an arrowhead on top. Note that in the DA-depleted microcircuit, a dominant ensemble activates more recurrently than the others (c). However, after CtxS, activity of ensembles alternates more between different ensembles. (C) Network states transition cycles. Before the CtxS, a network state activates recurrently (pseudo-loop) with little participation of other states. After the stimulus, transitions between states become more frequent showing closed cycles and reverberating dynamics.

Wallis ANOVA with *post hoc* Dunn tests). After cortical stimulation, the DA-depleted microcircuit did not significantly increase its cumulative activity in spite of the changes induced in circuit behavior (Fig. 2). Similar results were found when we measured significant peaks of coactivity (Fig. 3C). Only the analysis of cumulative distributions of individual cellular activity showed that, first, non-stimulated control circuit activity distribution is different from all other distributions ($P \leq 0.0000124$), and second, that cellular activity distribution of the DA-depleted microcircuit was different to the one found after CtxS, both in control ($P = 0.000205$) and in DA-depleted stimulated circuits ($P = 0.000043$; Fig. 3D; Ctrl $n = 116$ cells, Ctrl + CtxS $n = 161$ cells, DA-depleted $n = 440$ cells, DA-depleted + CtxS $n = 180$ cells; Kolmogorov–Smirnov tests). We conclude that the differences between control and pathological microcircuits do not mainly consist of differences in global neuronal activity but more subtle differences in network behavior and composition.

Cellular activity in the DA-depleted striatum before and after cortical stimulation

Because changes in global neuronal activity cannot explain changes in circuit behavior in the DA-depleted microcircuit after CtxS, we asked whether CtxS induces change in the neuronal subpopulations making up circuit activity by comparing neuronal activity present in the circuit before and after CtxS. Simply, cells were classified into three classes (i, ii, iii) according to their activity before and after CtxS (Fig. 4A): cells that decreased or stopped their activity after CtxS (i), cells with constant activity before and after CtxS (ii) and cells whose activity increased or that became recruited into the circuit after CtxS (iii). A decrease or increase in 20% of cellular activity was used as threshold to classify neurons into the different groups. If the activity changed in a smaller proportion, cells were considered as constant activity cells (ii). Cells that changed their activity (i, iii) are illustrated in Fig. 4B. This analysis showed that while some cells stopped or decreased their activity, others began or increased their activity after CtxS. Finally, we quantified the contribution of each population before and after CtxS, for all the experiments. Before CtxS, most of the activity was generated by group 'i' (62%). After CtxS, most of activity (64%) came from group 'iii'. This change in active neuronal subpopulations might explain the changes in microcircuit dynamics observed in Fig. 2. Therefore, besides changing the microcircuit's activity, CtxS recruits a new neuronal subpopulation while stopping the firing of another subpopulation; this effect of CtxS lasted for at least 30 min. Over longer periods of time (> 30 min), the effects of the stimulus were lost.

Figure 5 shows an experiment in which neuronal activity was followed over a longer period of time. Figure 5A is the raster plot of neuronal activity. Each row represents the activity of a single cell over the course of the experiment, and three temporal segments or epochs of activity are shown divided by vertical dotted lines (1–3). Epoch 1 is a sample of the activity before stimulation, Epoch 2 is the period right after the stimulus, and Epoch 3 is at least 30 min after the stimulation. According to the activity in each epoch, cells were divided into five groups (i-v, right part of the raster), according to their decrease, increase or no change in their activity in any of

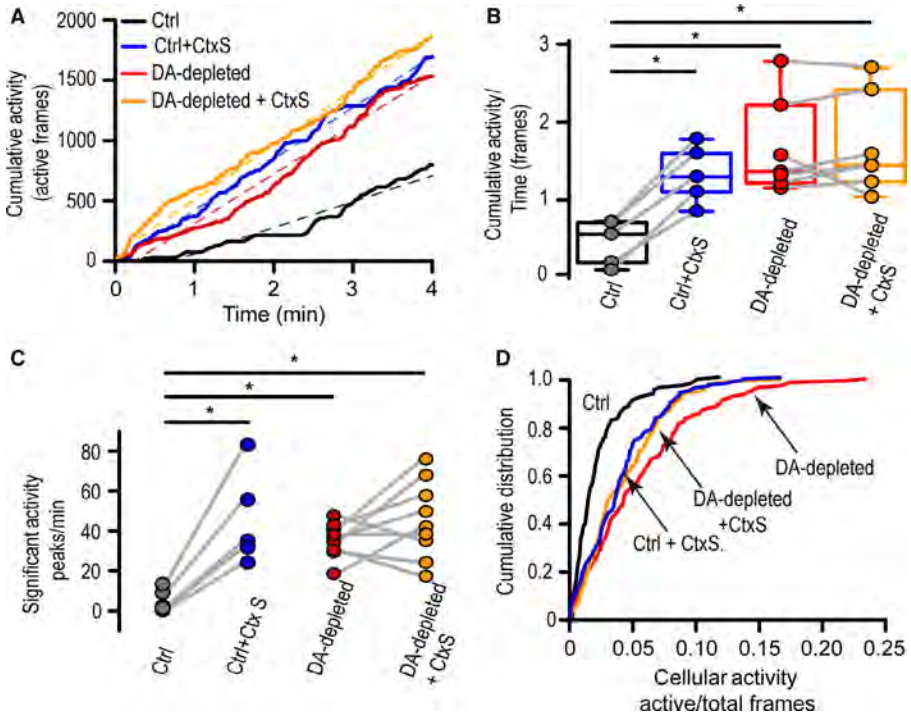

FIG. 3. Neuronal cumulative activity in the striatal microcircuit under different conditions. (A) Continuous lines: cumulative activity (sum of coactive cells per frame along time) of single representative experiments under different conditions: control without stimulus (Ctrl), cortical stimulation in control conditions (Ctrl + CtxS), DA-depleted striatal microcircuit without stimulus (DA-depleted) and DA-depleted striatal microcircuit after a cortical stimulus (DA-depleted + CtxS). Straight lines (dashed) are fitted to the data. (B) Cumulative activity over time for all the experiments. Box plots show the distribution of slopes from the lines fitted to cumulative activity (shown in A) for all of the experiments and conditions. There is a significant increase in neuronal activity after CtxS in control conditions ($P < 0.05$). DA depletion also shows increased activity compared to the controls without stimulation ($P < 0.05$). There is no significant increase in activity between the stimulated control and DA-depleted microcircuits. CtxS does not significantly increase the total activity of the DA-depleted microcircuit; it only changes the behavior of the circuit (Fig. 2). (C) Number of significant coactivity peaks before and after CtxS in Ctrl and DA-depleted microcircuits ($P < 0.05$). (D) Average cumulative distribution functions of cellular activity over time for all experiments and conditions. The cumulative distribution of cellular activity in non-stimulated controls is different to all other conditions ($P \leq 0.0000124$). The activity distribution of the stimulated control circuit is similar to that from the stimulated DA-depleted microcircuits ($P \leq 0.000205$; Ctrl $n = 116$ cells, Ctrl+CtxS $n = 161$ cells, DA-depleted $n = 440$ cells, DA-depleted + CtxS $n = 180$ cells; Kolmogorov–Smirnov tests) (Global Kruskal–Wallis ANOVA for (B) and (C): $P < 0.05$). '*' indicates statistical significance.

the three epochs, using a 20% change as threshold. As shown in Fig. 5C, group i reduced its activity after CtxS but has high activity before and 30 min after CtxS (epochs 1 and 3). Cells in group ii have high activity before CtxS, but their activity goes down after CtxS, and it does not return at a later time (epochs 2 and 3). Group iii becomes more active right after CtxS and even more active 30 min after CtxS (epochs 2 and 3). Group iv cells show the highest activity right after CtxS. Group v has nearly constant activity at all times. We made coactivity histograms for each population and compared them with the whole coactivity histogram (Fig. 5B; gray histogram in the background) to better illustrate the contribution of each neuron group to the whole circuit activity. For example, the greater contribution right after the CtxS was from group iv. To conclude, individual neuronal activity changes after CtxS and this change is reverted 30 min after the stimulus. We next investigated how these changes in neuronal activity rearrange microcircuit dynamics after CtxS.

Changes in architecture and dynamics of the DA-depleted microcircuit after cortical stimulation

Functional neuronal network connectomics was used to follow the changes that CtxS induces in the DA-depleted striatum (Fig. 6). In each graph, the nodes are active neurons during an epoch represented by circles in the periphery of a circular visualization, and functional connections were chosen as the moments of neuronal coactivity in an activity peak. One type of graph used the groups of cells as defined in Fig. 5; neurons were grouped according to the changes in activity they undergo after CtxS (Fig. 6A2 and 30 min after CtxS; Fig. 6A3). It can be seen that some neuron groups get most connections before CtxS (i and ii), while after CtxS, other groups come into action and become highly connected (iii and iv) although groups i and ii remain active. However, 30 min after CtxS, most connected groups change again: Group i recovers its connections, and surprisingly, group iii remains strongly connected while group iv is severely reduced in the number of neurons and connections (Fig. 6A3). Taken together, these data indicate that the microcircuit is temporarily remodeled by CtxS.

We also used a more traditional way to group the same neurons: those neurons making up the significant activity peaks in the coactivity histograms built from raster plots of neuronal activity in Figs 1 and 2 defined as neuronal ensembles (Carrillo-Reid *et al.*, 2008, 2011; Pérez-Ortega *et al.*, 2016). This neuronal ensemble definition is based on the proved Hebbian assumption that neurons that fire together have preferential connections with each other (Carrillo-Reid *et al.*, 2016), nodes again are seen as circles in the perimeter. These different ways of analyzing neuron groups do not coincide because in this case, neurons may belong to more than one

INFORME DE LABORES 2019

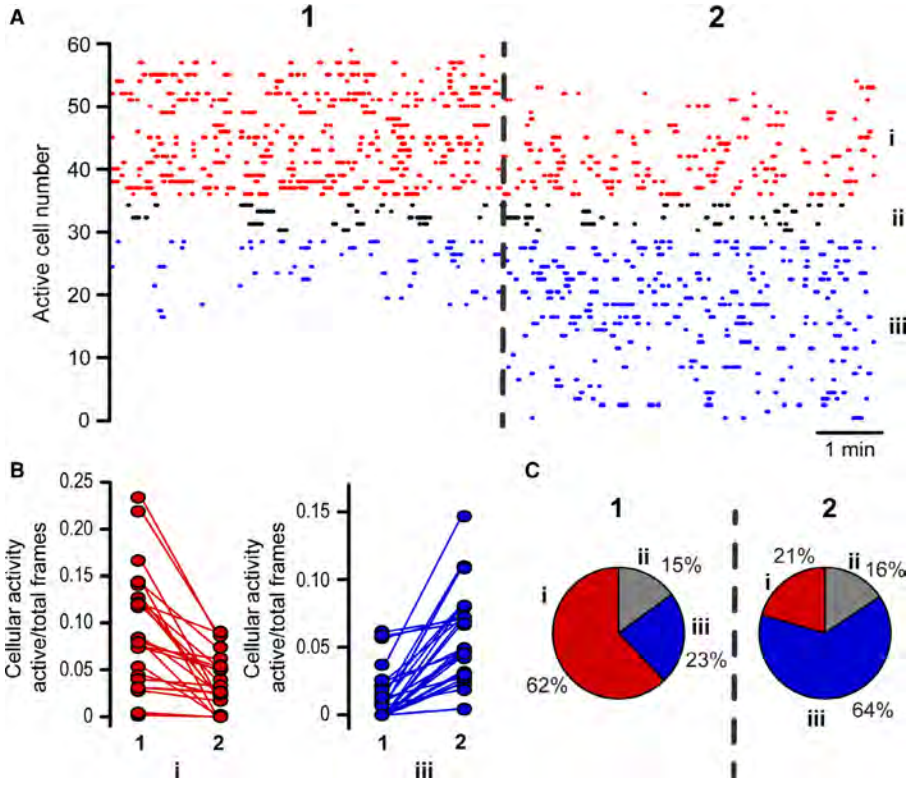

FIG. 4. Changes in neuronal subpopulations before and after cortical stimulation in the DA-depleted striatal microcircuit. (A). Raster plot of a representative experiment of CtxS in a DA-depleted slice. Each row represents the activity of a single neuron over time. Neurons were sorted and grouped according to the activity before (1) and after CtxS (2, dashed line). The neurons at the top: had greater activity before the stimulus and reduced or stopped their activity after the stimulus (i). Neurons at the bottom enhanced their activity after the stimulus or were even recruited by the stimulus; hence, they were not active before (iii). Middle neurons had similar activity in both conditions (ii). The threshold to consider a change in activity as significant was a decrease or increase in 20% from one epoch to the other. (B) Activity of the neurons classified into each group before and after the stimulation. Cells in group "i" decreased their activity after CtxS. Some of these cells stopped their activity. Activity of cells in group iii increased after CtxS, while many other cells in this group began their activity after CtxS. C. Pie plots illustrating percentages of activity generated by neurons classified into groups i–iii, in each epoch, for all the experiments. There was significant change in neuronal subpopulations active (n = 10 microcircuits, 451 cells, contingency of pie charts $P < 0.0001$) after CtxS.

ensemble or significant peak of coactivity (neurons that participated in more than one ensemble are indicated by labels). Functional connections are still defined as moments of coactivity. In spite of the different grouping methods, both networks show similar phenomena after CtxS, suggesting intrinsic robustness. Before CtxS (Fig. 6B1), most connections were monopolized by ensemble 'b'; this state of affairs changed after CtxS (Fig. 6B2) when several ensembles connect with each other and a group of neurons participate in all ensembles. Finally, 30 min after the stimulus (Fig. 6B3), ensemble 'b' becomes again the one with more neurons and gets most of the connections. To summarize, both methods of graphing show that CtxS changes both the neurons participating in the circuit as neuronal ensembles and their connectivity. Moreover, if each main group from the ensembles coactivity networks is taken as a network state, we can see that transitions between network states show a different evolution after CtxS.

Thus, time sequences of transitions between network states show that before CtxS (Fig. 6C1), state 'b' is dominant as it is the most recurrent and attracts more transitions. Right after the stimulus (Fig. 6C2), transitions between all three main ensembles are more balanced; 30 min after the stimulus (Fig. 6C3), the pathological dynamics returns: Network state 'b' becomes the most recurrent and transitions decrease as though the circuit gets trapped in one state. To conclude, a cortical stimulus changes the architecture and dynamics of the DA-depleted microcircuit even if neuronal activity remains high as compared to the control non-stimulated microcircuit (Fig. 3B). Previous work has shown that application of L-DOPA turns the DA-depleted microcircuit less active, similar to the control non-stimulated microcircuit (Plata *et al.*, 2013a). However, it has not been shown whether this less active microcircuit would resemble the control-stimulated microcircuit upon CtxS (Fig. 3B).

Effects of cortical stimulation in the presence of L-DOPA actions in a DA-depleted microcircuit

Figure 7 is similar to Fig. 5; it shows changes in neuronal activity in the DA-depleted microcircuit under two different treatments, first, the administration of 10 μM L-DOPA, and second, a cortical stimulation (CtxS) during L-DOPA actions. The aim was to see whether the evoked circuit activity during L-DOPA corresponds more to a control-stimulated circuit or, else, better resembles the pathological network. Experiments were followed more than 30 min. Neurons were divided into five groups (i–v), according to their change in activity during the different epochs of the experiment. The raster plot (Fig. 7A1) and the histogram of coactivity (Fig. 7B1) show what neuronal subpopulations were preferentially activated in the DA-depleted microcircuit before the stimuli i and ii. After adding L-DOPA to the superfusion, activity of all neurons decreased (Figs 7A,B2; Plata *et al.*, 2013a); thus, Epoch 2 when L-DOPA was administered was not considered for measuring activity changes as

© 2017 Federation of European Neuroscience Societies and John Wiley & Sons Ltd

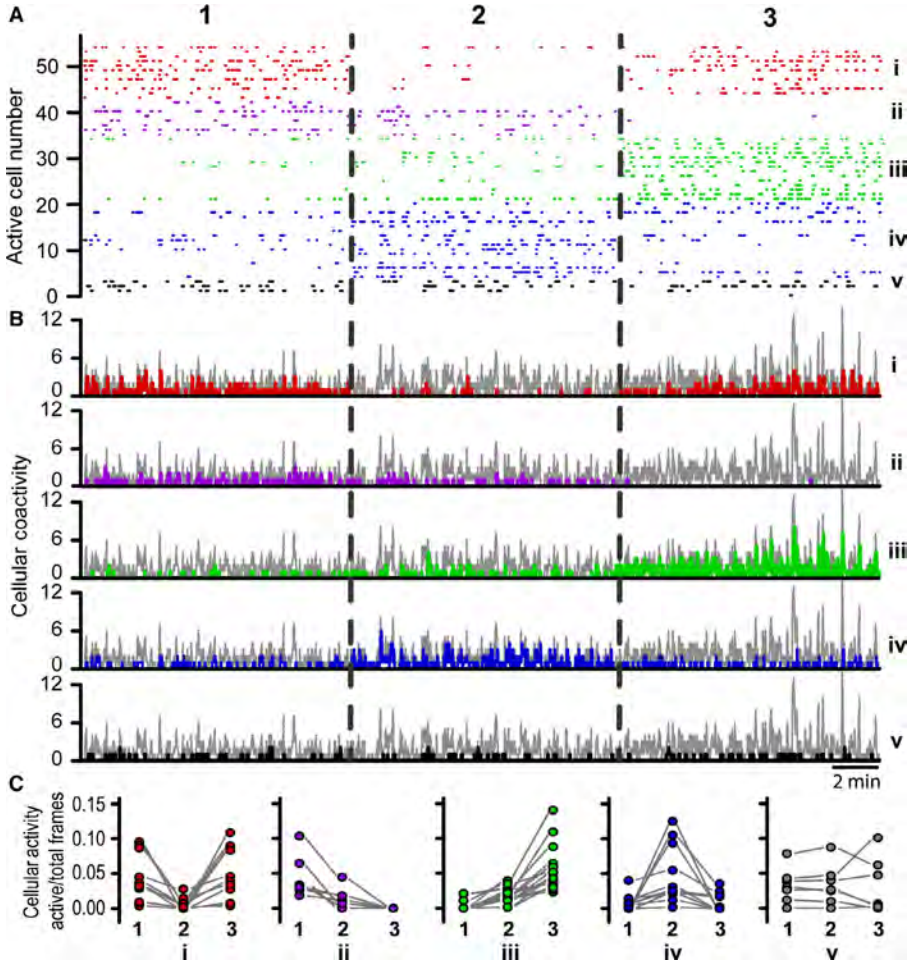

FIG. 5. The effects of cortical stimulation on the DA-depleted microcircuit are temporary. Thirty minutes after CtxS, the active neuronal subpopulations change again. The present representative experiment was divided into three epochs (1–3). (1) Before stimulation, (2) right after CtxS and (3) > 30 min after CtxS. (A) The raster plot of neuronal activity shows three fragments of each epoch divided by vertical dashed lines, the moment of CtxS was removed. Each row represents the activity of a neuron during the three epochs. Neurons were divided into five subpopulations according to their activity in each epoch: (i) Neurons that had high activity before CtxS, low activity right after CtxS, and recovered or had larger activity 30 min after CtxS. (ii) Neurons that had high activity before CtxS, less activity right after CtxS and that did not recover their activity 30 min after CtxS. (iii) Neurons with low or no activity before CtxS, which increase their activity right after CtxS and even more activity 30 min after CtxS. (iv) Neurons with the greatest activity right after CtxS but less activity before and 30 min after CtxS. (v) Neurons that kept constant activity before and after CtxS. The threshold to consider a significant change in activity was 20%. (B) Contribution of each neuronal subpopulation to the whole coactivity histogram. The histogram of each neuronal subpopulation (i–v) is shown over the total histogram (light gray) to demonstrate the contribution of each subpopulation per epoch. (C) Activity of each cell group per epoch (1–3) divided into the different subpopulations (i–v).

no significant peaks of coactivity were present. After CtxS (Figs 7A,B3) activity clearly increased, however, a recruitment of different neuronal subpopulations which now contribute to the circuit activity resembling a control-stimulated circuit is observed (e.g., iii and iv), these subpopulations do not participate in the initial pathological dynamics. Thirty minutes after CtxS in the presence of L-DOPA (Figs 7A,B4), a set of neurons that were active before the administration of the drug and CtxS reactivate. A subpopulation of neurons (v) did not change its activity along the experiment. The contribution of each subpopulation to the total histogram of activity is shown in Fig. 7B. Figure 7C shows the activity of each neuron set during epochs 1, 3 and 4. We conclude that the DA-depleted microcircuit reconfigures itself after L-DOPA plus CtxS differentially changing the activity of diverse neuronal subpopulations.

Next, we asked how the architecture and dynamics of the remodeled microcircuit change under these conditions. To appreciate the remodeling in microcircuit architecture and dynamics, we built two types of networks (Fig. 8; cf. Fig. 6). One points out the subpopulations of neurons that change their activity after L-DOPA and CtxS (Fig. 8A epochs 1, 3, 4), and the other one shows the neurons that form part of the neuronal ensembles during the significant peaks of coactivity (Fig. 8B epochs 1, 3, 4). In the first case, the number of elements making the groups as well as their connections changed after L-DOPA and CtxS and tended to return to the original circuit after 30 min. In the second case, there is a dominant ensemble 'b' in the original DA-depleted microcircuit (Jáidar *et al.*, 2010; Pérez-Ortega *et al.*, 2016) that clearly stays after L-DOPA plus CtxS. However, it allows more transitions between ensembles after CtxS in the presence of L-DOPA, and its preponderance does not return after 30 min. When we make the time sequence of transitions between main ensembles or network states (Fig. 8C epochs 1, 3, 4), clearly the number of transitions between the three states increases. In contrast to the experiment without L-DOPA, they remain alternating their activity after 30 min. We conclude, first, that L-DOPA decreases the activity of the DA-depleted microcircuit in a way that significant peaks of coactivity become hard to observe,

INFORME DE LABORES 2019

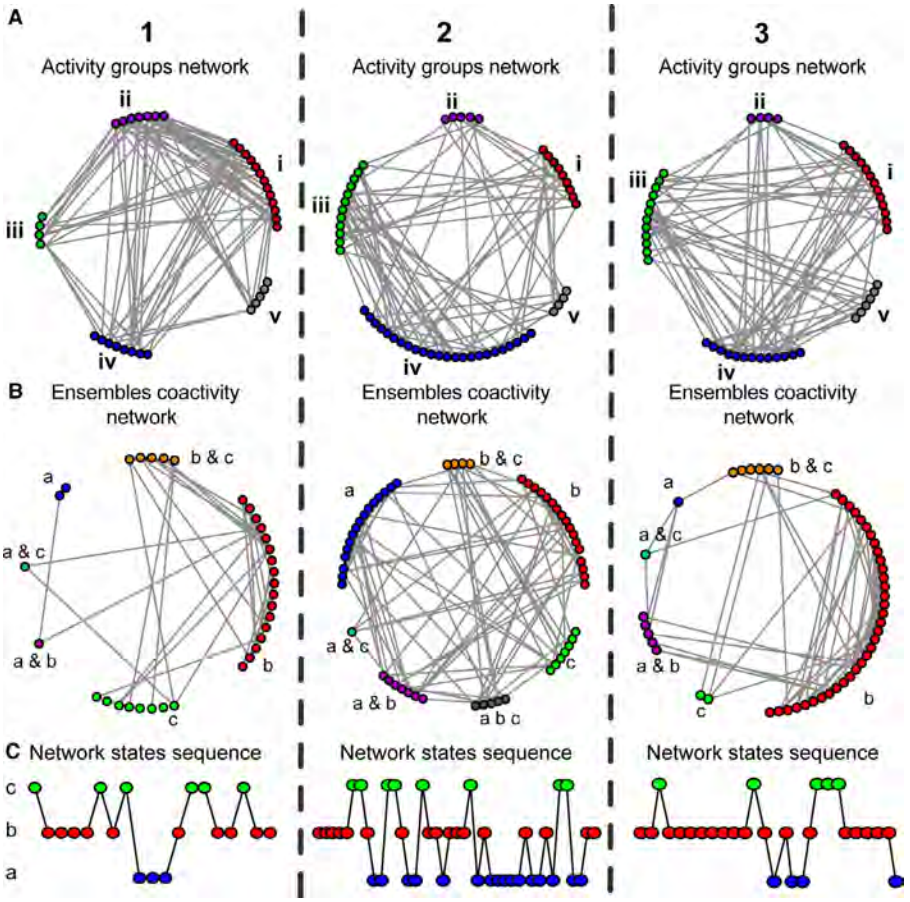

FIG. 6. The effect of corticostriatal stimulation on microcircuit architecture and dynamics. We illustrate microcircuit architecture with two types of graphs: activity group networks and ensembles coactivity networks. (A) Activity group networks separate groups of neurons (nodes represented by circles in the perimeter) according to their activity before (1), right after (2) and 30 min after (3) the cortical stimulus (Fig. 5). The functional connections between them (gray lines, see Methods) indicate moments of coactivation in significant activity peaks. Only active neurons during a given epoch are represented. Before CtxS groups i and ii get most connections, after CtxS group iii and iv have most connections but members of groups i and ii remain connected. Thirty minutes after CtxS, group i recovers many connections and surprisingly group iii remains strongly connected while group iv is severely decreased. (B) Ensemble coactivity networks are sets of neurons (nodes seen as circles in the periphery) that form significant peaks of coactivity in the coactivity histograms obtained from the raster plots (Figs 1 and 2). There can be neurons belonging to more than one ensemble. Functional connections are also defined as moments of coactivity. Groups of neurons in (A) and (B) do not coincide since they illustrate divergent ways to define neuronal groups; however, they show similar phenomena. Neurons that participated in more than one ensemble are indicated by labels. Still, note that before CtxS (1), most connections are monopolized by ensemble b, right after the stimulus (2) several ensembles share connections and one of them has neurons that belong to all ensembles, and finally, 30 min after the stimulus (3) the b ensemble has recruited more members and gets most connections again. C. Time sequences of network states illustrate the dynamics of such architectures: before CtxS most transitions occupy state b (1), right after CtxS (2) the number of transitions increases between the three major ensembles and 30 min after CtxS (3) the dominant ensemble returns, transitions decrease and the network gets trapped most time in network state b.

thus dissolving the most recurrent activity of the dominant ensemble (Plata *et al.*, 2013a). In addition, when the circuit was turned on by a CtxS in the presence of L-DOPA actions, it did not behave as the pathological DA-depleted circuit but showed alternating behavior between ensembles. In contrast to CtxS without L-DOPA, it remains behaving this way after 30 min. Thus, the striatal microcircuit became functional for a longer period of time.

Because cumulative distributions of cellular activity showed statistical differences between different treatments (Fig. 3D), we compared these distribution with those obtained with both cortical stimulus and L-DOPA (Fig. 9) taking into account all cells from all samples. In the case of CtxS only, cumulative distributions for DA-depleted microcircuits have a significant difference with the initial distribution right after CtxS ($P \leq 0.0135$; Figs 3D and 9A). However, this difference is lost 30 min after the stimulus (Fig. 9A).

In the case of CtxS plus L-DOPA, Fig. 9B shows, first, that L-DOPA reduced cellular activity in the DA-depleted microcircuit ($n = 7$, Wilcoxon t-test $P = 0.015$, data not shown). Second, after CtxS during L-DOPA actions, cumulative distribution of cellular activity increased as the circuit was turned on (Figs 2, 7, 8); however, it remained significantly different to the original cellular activity distribution of the DA-depleted microcircuit ($P = 0.00000003$). Third, in contrast with the case without L-DOPA, the circuit remained with this level of activity after 30 min. This means that in the presence of L-DOPA, the evoked activity by CtxS resembles that of a control-stimulated circuit and remains for longer periods of time. That is, L-DOPA reduces the activity to that of a control not activated circuit, and upon stimulation, it behaves as a control-stimulated circuit. Pie charts of Fig. 9C and D show the contribution of neuron groups as defined by their cellular activity (Figs 5, 7: i–v) under each condition and for all of experiments. Pie chart contingency chart tests show that there is no significant difference between equivalent experimental conditions in both sets of experiments: DA-depleted + CtxS (Fig. 9C) vs. DA-depleted + L-DOPA + CtxS (Fig. 9D). For DA-depleted neurons, most activity comes from subpopulations i and ii across all experiments ($P = 0.6227$ comparing

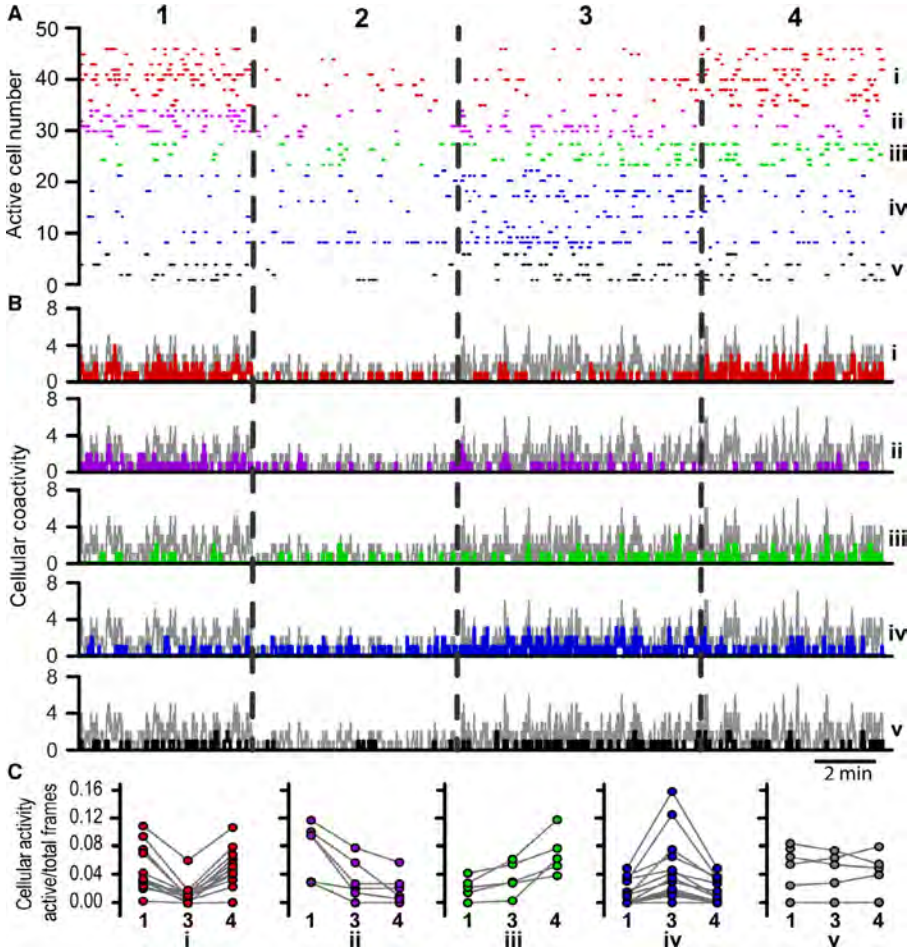

FIG. 7. Corticostriatal stimulation of the DA-depleted microcircuit during L-DOPA action. During the increased spontaneous neuronal activity of a DA-depleted microcircuit (1), 10 μM L-DOPA was administered in the bath saline (2); then, cortical stimulation was delivered (3), and activity was followed after 30 min (4). As in Fig. 5, neurons were sorted in the raster plot (A) and in the histograms of coactivity (B) according to their decrease or increase in activity and their participation in the whole activity is illustrated (pale histogram in the background). The threshold to consider a significant change in activity is 20%. During L-DOPA administration, all neuronal activity decreased to levels found in non-stimulated control microcircuits (2) and no significant peaks of coactivity were found in this experiment. Therefore, activity changes were compared only for epochs 1, 3 and 4 and neurons were divided into five subpopulations. (A) Sorted raster plot where each row is the activity of a single cell along time. (B) Coactivity histograms. Before stimulation (1), activity was high in neuron groups i and ii (C), after L-DOPA (2), activity decreased in all groups, and after CtxS in the presence of L-DOPA (3), activity returned; however, other neuron groups, iii and iv, contribute to the activity together with some neurons from groups i and ii. After 30 min of CtxS (3), activity in groups i and iii returned while that in groups ii and iv decreased. Neurons in group v did not change their activity except during L-DOPA. C. Activity of neuronal subpopulations during epochs 1, 3 and 4.

DA-depleted circuits from both sets of experiments). After CtxS without (Fig. 9C2) or with L-DOPA (Fig. 9D3), a significant renovation ($P = 0.0001$) of the neuronal subpopulations contributing to the circuit occurred: now group iv and part of group iii contribute with most neurons in the microcircuit, and there were no significant differences with or without L-DOPA ($P = 0.16$). Thirty minutes after CtxS, group i returns and group iv activity decreases in both samples while many neurons from group iii remain showing no significant differences with or without L-DOPA (Figs 9C3, D4; $P = 0.2078$). We conclude that CtxS reconfigures the active neuronal populations in the presence or absence of L-DOPA, but that 30 min after the stimulus, neuronal groups that sustained the DA-depleted microcircuit return. However, it is shown below that dynamics of these circuits differ depending on L-DOPA actions.

Figure 10A and B illustrates patterns of network states recurrence under different conditions in two samples of experiments (see recurrence index in Methods): DA-depleted + CtxS (Fig. 10A) and DA-depleted + L-DOPA + CtxS Fig. 10B). When a network state has a high pathological recurrence (Jáidar *et al.*, 2010; Pérez-Ortega *et al.*, 2016) with respect to the other states, the sample exhibits two different clusters and augmented variance as that seen in the left box of Fig. 10A, B (DA-depleted microcircuit). When no network states has a significant higher recurrence than the other states, sample distribution appears homogenous as a single cluster with no dominant network state, as seen in the middle box plots of Fig. 10A,B (DA-depleted circuits + CtxS and DA-depleted circuits + L-DOPA + CtxS). That is, CtxS eliminates the pathological ensemble in both cases: without ($P = 0.007586$; O'Brien test for Homogeneity of Variance in this and other P values of this section) and with L-DOPA ($P = 0.03712$), restoring ensembles alternation ($n = 12$ network states from four experiments in each condition obtained from eight different slices and animals). However, a difference between the two conditions was evident 30 min after CtxS: without L-DOPA highly recurrent pathological ensembles returned (Fig. 10A right box; $P = 0.01532$ compared with CtxS). In addition, highly recurrent ensembles appeared to be more recurrent than in the initial DA-

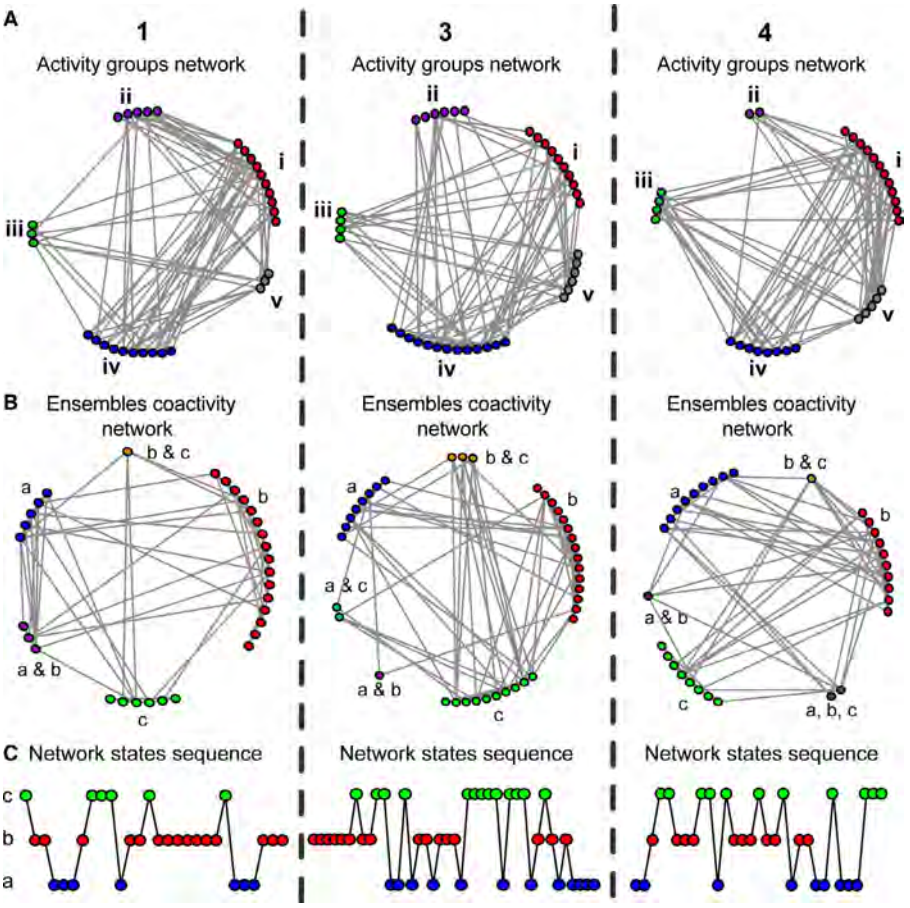

FIG. 8. The effects of L-DOPA and corticostriatal stimulation on the DA-depleted microcircuit architecture and dynamics. (A) Microcircuit built with neuronal subpopulations that changed their activity after the treatments: neuronal networks per epoch: (1) DA-depleted microcircuit before CtxS, circuit while L-DOPA is administered is omitted (2), (3) In the presence of L-DOPA, microcircuit right after CtxS and (4) 30 min after stimulation. Each neuron is a node (circles in the perimeter), each link is a moment of coactivity. Only active neurons in a given epoch are represented, and they are classified into groups according to Fig. 7 (i–v). See the changes in the number of elements and connections of each group after CtxS. (B) Ensembles coactivity networks composed by neurons that make significant peaks of coactivity: main ensembles a–c, neurons that participated in more than one ensemble are grouped separately as indicated by labels. Changes in ensembles and connectivity are obvious after CtxS in the presence of L-DOPA. (C) Network states time sequences per epoch. A more recurrent state (b) is not lost but allows more transitions to other states after L-DOPA and CtxS (3). In contrast to CtxS alone (cf. Fig. 6), transitions persist after 30 min.

depleted condition ($P = 0.01869$) as though the parkinsonian state returned worse than before. In contrast, in the presence of L-DOPA, the microcircuit remained without highly recurrent ensembles 30 min after CtxS (Fig. 10B right box; $P = 0.03582$ as compared to the original DA-depleted circuits). Taken together, these results demonstrate that even when neuronal subpopulation activity or neuronal ensembles tend to return after being temporarily reconfigured by CtxS (Figs 6, 8, 9), L-DOPA prevents the circuit to regain its pathological activity.

Discussion

Cortical stimulation in control and DA-depleted microcircuits

It is being discussed whether the signs and symptoms of parkinsonism have a cortical origin (Arbuthnott & Garcia-Munoz, 2016) as abnormal neuronal correlations are recorded in the motor cortex before motor signs of the disease are apparent (Li *et al.*, 2012). Some cortical influences over striatal circuitry and its changes during parkinsonism have been described (Calabresi *et al.*, 1996, 2015; Hammond *et al.*, 2007; Pérez-Ortega *et al.*, 2016). Accordingly, extradural cortical stimulation in patients (Cilia *et al.*, 2007; Bentivoglio *et al.*, 2012), transcranial magnetic stimulation of the cortex in patients and rodents (Kanno *et al.*, 2004; González-García *et al.*, 2011; Dileone *et al.*, 2017), direct motor cortex stimulation in primates and patients (Drouot *et al.*, 2004; Benninger *et al.*, 2010), optogenetic cortical stimulation in rodents (Gradinaru *et al.*, 2008; Sanders & Jaeger, 2016) and antidromic stimulation of corticofugal axons in rodents (Li *et al.*, 2007, 2012) all relieve parkinsonian signs. In the present work, we asked what the mechanisms are. Therefore, our aim was to observe the changes produced in the striatal microcircuit by cortical stimulation in *in vitro* brain slices of DA-depleted striata.

The control striatal microcircuit is characterized by having low spontaneous activity which increases during action initiation (e.g., Cui *et al.*, 2013). *In vitro*, we have shown that activity increases with network-related behavior after adding an excitatory drive to the superfusion saline such as NMDA at low concentrations (Grillner, 2006). Once turned on, microcircuit activity is characterized by exhibiting significant spontaneous peaks of neuronal coactivity that resemble neuronal ensembles, whose neurons work in concert. This allowed us to use neuronal coactivity in a given time frame to build functional connections and microcircuit representations (Carrillo-Reid *et al.*, 2008; Pérez-Ortega *et al.*, 2016). Network activity

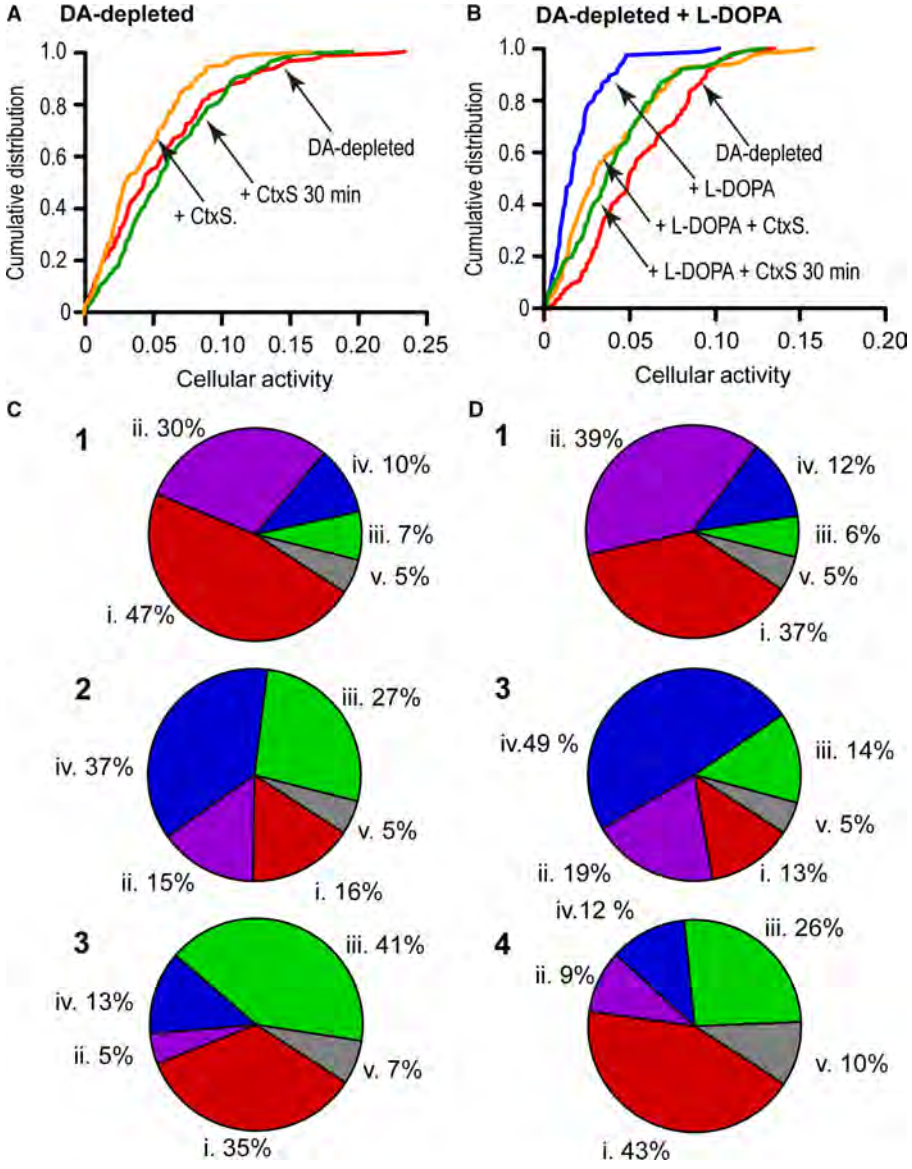

FIG. 9. Cellular activity groups under different conditions for all experiments. (A) Cumulative activity distribution of the cellular activity for the DA-depleted microcircuit treated with CtxS only: there is a significant difference between DA-depleted activity and DA-depleted plus CtxS distributions ($P \leq 0.0135$), this difference disappears after 30 min of the stimulus. (B) Cumulative activity distribution of the cellular activity for the cases of L-DOPA plus CtxS; there is a significant difference in activity after L-DOPA administration ($P = 9.4 \times 10^{-15}$). Activity is recovered after CtxS in the presence of L-DOPA and remains significantly different than that of the DA-depleted microcircuit ($P = 0.00025$). In contrast to CtxS alone, activity distribution remains significantly different after 30 min when L-DOPA was present ($P = 0.0253$; Kolmogorov–Smirnov tests). (C, D) Pie charts illustrating the contribution of different neuronal subpopulations as classified by their activity before and after CtxS (see Figs 5 and 7) for all experiments pooled together. (1) Groups i and ii were predominant in DA-depleted circuits in both cases ($P = 0.6227$). After CtxS, a significant renovation in the neuron subpopulations making up the circuits was observed without (C2) and with L-DOPA (D3). A rise in the neurons of group iv was evident in both cases ($P < 0.0001$), but there was no significant difference in this neuronal redistribution without or with L-DOPA ($P = 0.16$). Thirty minutes after CtxS, group i returns and group iv decreases in both cases ($P = 0.2078$ comparing C3 and D4). Contingency pie chart tests.

revealed high-order processing as ensembles show recurrence and alternating activity with reverberating closed cycles during various minutes, and are modulated in different ways by cholinergic or dopaminergic agonists (Carrillo-Reid *et al.*, 2009, 2011). *In vivo* research has shown that, indeed, this activity encodes motor actions in space (Klaus *et al.*, 2017). Here, we show that it is possible to evoke this network behavior without adding chemical excitatory drives such as NMDA, and instead, using an adequate cortical electrical stimulus (see Methods and Fig. 1). Once it is evoked, microcircuit activity can be followed for more than 30 min in brain slices *in vitro*. Activity recorded in the striatal microcircuit arises from several neuronal subpopulations. Some cholinergic and GABAergic interneurons have spontaneous activity (Goldberg & Wilson, 2010; Tepper *et al.*, 2010), which suggests that they are participating in the microcircuit. Additionally, both low threshold spiking interneurons and cholinergic interneurons communicate with each other through ionotropic and metabotropic receptors (Elghaba *et al.*, 2016).

The DA-depleted parkinsonian microcircuit has dynamics that radically differ from that of the control microcircuit (Jáidar *et al.*, 2010; López-Huerta *et al.*, 2013; Plata *et al.*, 2013a; Pérez-Ortega *et al.*, 2016). A dominant neuronal ensemble with a high level of

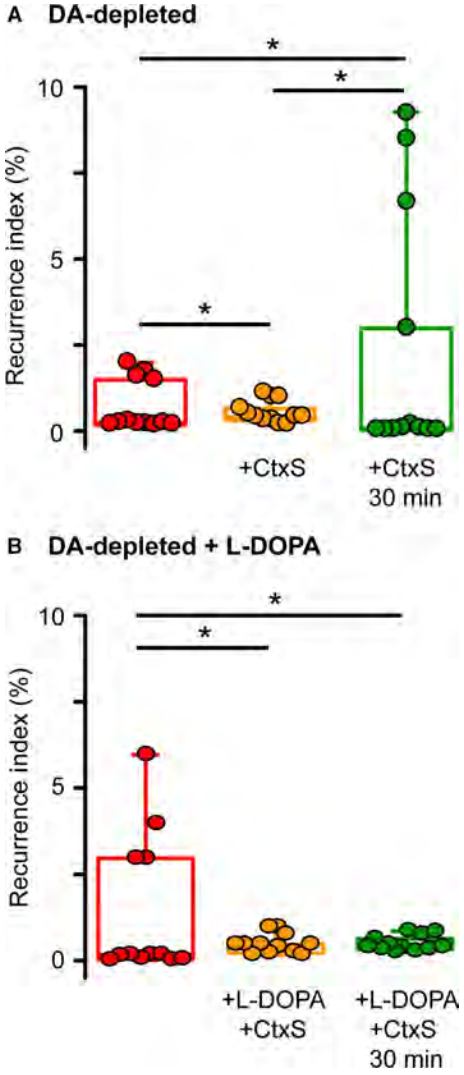

FIG. 10. Recurrence of network states. To test whether the recurrence is predominant in certain network states, we calculated the recurrence of each network state with respect to the others across all experiments (see Materials and methods). In the case some network states have an excess of recurrence (dominant pathological states), the circuit will be divided into two populations of network states those with high and those with low recurrence and the variance of that sample will reflect this separation. In the cases where there is no predominance of any network state, all of them would have similar recurrence and sample variance would be smaller. (A) Box plots comparing recurrence of network states in DA-depleted circuits before and after CtxS: before CtxS, there clearly are two subpopulations of network states one of them with higher recurrence than the others (left). After CtxS, all networks states tended to group together (middle; $P = 0.007586$ with respect to DA-depleted circuits). However, 30 min after CtxS, network states separated again and dominant networks states became even more recurrent (right; $P = 0.01532$ with respect to CtxS and $P = 0.01869$ with respect to DA-depleted circuits before CtxS), suggesting that the parkinsonian state returned worse than before. (B) Comparison of network states recurrence before and after CtxS plus L-DOPA. DA-depleted circuits showed network states with high and low recurrence (left). After CtxS during L-DOPA actions, all network states tended to have the same recurrence (middle; $P = 0.03712$ with respect to DA-depleted circuits). In contrast to the case without L-DOPA, 30 min after CtxS in the presence of L-DOPA, the circuits remained with network states with the same incidence of recurrence (right; $P = 0.03582$ with respect to the DA-depleted circuits). $N = 12$ network states taken from four different circuits and slices from different animals. (O'Brien Homogeneity of Variance test). '*' indicates statistical significance.

recurrence absorbs most neurons and connections in the observed circuits, thus trapping them in a single network state during most of the time (Figs 2, 9, 10). Transitions between network states become scarce, which is very metaphorically, as it corresponds to the motor impairment shown by parkinsonian subjects. By obtaining a recurrence index (see Materials and methods and Fig. 10), we found that DA-depleted microcircuits divide their ensembles into those with high and those with low recurrence, thus increasing the variance. Because previous reports show that cortical stimulation ameliorates Parkinsonism, we wanted to confirm this *in vitro*. Observing whether ensembles with high recurrence are decreased. Thus, another finding of this work is that cortical stimulation releases the microcircuit activity from the parkinsonian state, allowing the circuit to return to ensembles alternation and transitions. By observing graphed microcircuits built with single neurons as nodes and coactivity time frames as the functional connections, it is seen that highly recurrent ensembles that monopolize most activity and connections decrease, leaving way to more balanced connections among different ensembles. In patients, this phenomenon can be related to events of *Kinesia Paradoxa*, in which a strong sensory input may temporarily alleviate the signs of PD (Banou, 2015). In addition, new neuronal subpopulations are recruited into the active circuit and other neuronal subpopulations, that sustain the pathological state, stop firing. Some neurons lower their activity while others increase it. A working hypothesis to explain how some neurons are either silenced or recruited probably would involve the action of striatal inhibitory interneurons known to receive special large numbers of cortical synapses (Bennett & Bolam, 1994; Gittis *et al.*, 2010; Planert *et al.*, 2010). These interneurons have also been reported to connect densely with striatal projection neurons (Straub *et al.*, 2016). Apparently, these interneurons are necessary to observe control network activity such as neuronal ensembles alternation and reverberatory behavior (Pérez-Ortega *et al.*, 2016). To conclude, a cellular substrate that may explain how cortical stimulation may be acting to alleviate parkinsonism was encountered. This finding correlates with changes in long-term synaptic plasticity found in DA-depleted striatal synapses (Calabresi *et al.*, 1996; Ghiglieri *et al.*, 2012). Nonetheless, the effects of CtxS on the DA-depleted microcircuit only last for a few minutes. After 30 min, most tested microcircuits had returned to the parkinsonian state.

The most used treatment for PD is L-DOPA which greatly ameliorates motor signs (Mercuri & Bernardi, 2005) and improves somatosensorial responses (Ketzef *et al.*, 2017). *In vitro*, L-DOPA has been shown to help in the recovery of control long-term synaptic plasticity (Ghiglieri *et al.*, 2012). In agreement with previous data, the present results demonstrate that L-DOPA returns the DA-depleted striatal microcircuit into a low-activity circuit, similar to the one found in control conditions (Plata *et al.*, 2013a). Therefore, a main question to ask was whether in the presence of L-DOPA, activity evoked in the striatal DA-depleted microcircuit corresponds to the alternating activity between neuronal ensembles similar to the one found in control conditions or else the pathological circuit comes into action. We found that cortical stimulation during L-DOPA actions induces new subpopulations of neurons to activate while many neurons that were active during pathological activity become silent.

In the presence of L-DOPA, CtxS produced network activity similar to control-stimulated circuits and similar to CtxS of DA-depleted circuits. However, in contrast to CtxS without L-DOPA, L-DOPA allowed circuits to remain as in control conditions for longer periods of time. Cumulative distribution of cellular activity did not return to

© 2017 Federation of European Neuroscience Societies and John Wiley & Sons Ltd

resemble the DA-depleted microcircuit during the rest of the recording period even though cells that participated in the pathological state reactivated. Therefore, not all phenomena can be explained with changes in neuronal participation. In the presence of L-DOPA, changes in network dynamics evoked by cortical stimulation such as alternation between neuronal ensembles and closed cycles of reverberatory activity lasted for the rest of the recording period (more than 30 min), even when much activity of original subpopulations of neurons returned. Neuronal ensembles that monopolized most activity in the pathological microcircuit were dissolved, and more balanced connections and alternations with other ensembles remain.

If we think of the cortical stimulation as the command that initiates action, the action initiated in the presence of L-DOPA was more similar to the control-stimulated microcircuit, than to the pathological one.

In conclusion, L-DOPA and cortical stimulation work synergically. Therefore, the question becomes whether the two treatments may be balanced somehow as to reduce L-DOPA dosage if continuous cortical stimulation devices are developed.

Streptomyces are mycelial bacteria adapted to grow in soil. They have become important producers of biomolecules with medical applications, but their growth in industrial fermenters is challenged by their peculiar morphology in liquid culture: the hyphae tend to clump and grow as large pellets, which are oxygen- and nutrient-limited, grow slowly and present diminished protein production. Here, by implementing an experimental evolution strategy, a *S. coelicolor* strain, 2L12, with dispersed morphology and reduced pellet size in liquid culture and no defects in either differentiation or secondary metabolism was selected. Genome sequencing revealed a single amino acid substitution in a sensor kinase, Sco5282, of unknown function to be responsible for the morphological changes. Moreover, genetic and biochemical scrutiny identified Sco5283 as the cognate response regulator and demonstrated that the acquired mutation activates this two-component system. Finally, transcriptomic analysis of the mutant strain revealed changes in expression of genes involved in central processes such as glycolysis, gluconeogenesis, stress-signaling pathways, proteins secretion and cell envelope metabolism. Thus a novel two-component system is proposed to play a key role in the control of *Streptomyces* extracellular metabolism.

INTRODUCTION

Streptomyces is a genus of soil-dwelling mycelial actinobacteria (Hopwood, 2007). In the presence of nutritious substrates in the soil, their spores are able to germinate, leading to growth of hyphae that adhere to the soil particles and to each other, and grow as a packed vegetative mycelium (Bobek et al., 2017). When conditions become suboptimal, they go through a developmental program, growing out of the soil and forming the reproductive aerial mycelium (Flärdh and Buttner, 2009). There is a concerted lysis of the vegetative hyphae, which releases nutrients for the growing aerial mycelium (Manteca et al., 2005). During this stage antibiotics are also produced preventing

competitors from feeding on the lysed mycelium. Subsequently aerial hyphae septate by undergoing synchronous cell divisions, which later become chains of spores. This is the only stage of the *Streptomyces* life cycle in which unigenomic cells exist (Bush et al., 2015; Zhang et al., 2016).

This genus has been widely studied because of the vast array of antibiotics they produce. In recent years many species have also been exploited for the production of heterologous proteins. Because of their mycelial morphology, *Streptomyces* growth in liquid media is unlike that of unicellular bacteria. For example, germinating spores of the model organism *S. coelicolor* tend to clump together, and the hyphae stick to each other, leading to growth as tight mycelial pellets (Zacchetti et al., 2016). As a consequence, the inner hyphae have limited access to nutrients and oxygen (Walisko et al., 2015), leading to slower growth rates. This morphology in liquid cultures has also a clear impact on production of different molecules: while pelleted forms present increased antibiotic synthesis (Martin and Bushell, 1996; Manteca et al., 2008) they are disadvantageous for protein production, because of the reduced contact with inducer molecules (van Wezel et al., 2006).

For this reason, strategies have been developed to control the morphology of mycelia in liquid culture. Increasing agitation or viscosity of the medium (by addition of sucrose, for example) are simple methods that intensify shear forces, reducing aggregation but also increasing energy input and mechanical stress on the cells (van Dissel et al., 2014). A different approach has been to engineer strains where hyphae do not aggregate. For example, deletion of *cslA*, which encodes a cellulose synthase-like enzyme, leads to pellet dispersion. However, this mutant also exhibits pleiotropic effects on growth and differentiation (Xu et al., 2008). A different set of genes, *matAB*, were identified among the mutations in a dispersed-growing strain of *S. lividans*, a close relative of *S. coelicolor*, isolated from a chemostat after 100 generations (van Dissel et al., 2015). These genes were initially identified for their similarity to a biofilm operon of *Staphylococcus* spp., and their deletion was sufficient to induce dispersed growth in both *S. lividans* and *S. coelicolor* (van Dissel et al., 2015). More recently the *mat* genes have been shown to be responsible for synthesis of extracellular poly-β-1,6-*N*-acetylglucosamine, which provides hyphal adhesion to hydrophylic surfaces (van Dissel et al., 2018).

We sought to isolate new strains of *S. coelicolor* with a dispersed-growth phenotype through directed evolution. A study about the origin of multicellularity in the unicellular yeast *Saccharomyces cerevisiae* described an experimental evolution method to isolate aggregating mutants, based on the selection of fast-sedimenting cell clumps, eventually obtaining "multicellular" strains (Ratcliff et al., 2012). We adapted this method to obtain slower sedimenting *S. coelicolor* strains by applying the opposite selection: subculturing the slower sedimenting pellets. One of the obtained strains, 2L12, showed significantly reduced pellet size and dispersed growth even in medium without sucrose, although its secondary metabolism and differentiation in solid medium was not affected. We show that this phenotype is caused by an activating mutation in a histidine kinase of a novel two-component system. Finally, transcriptomic analysis of the 2L12 mutant strain revealed molecular targets able to explain the dispersed growth phenotype of the selected mutant strain.

MATERIALS AND METHODS

Streptomyces Cultures

Streptomyces spores were obtained from MS agar plates and preserved in 20% glycerol at −20°C (Kieser et al., 2000). Liquid cultures were grown in LB + 25% sucrose or 2xYT (Kieser et al., 2000), without sucrose. Growth curves were performed in 2xYT or YEME media (Kieser et al., 2000), using freshly harvested spores to give an initial OD_{450} = 0.01. Samples (10 mL) were taken at the indicated times and filtered through 0.45 μm cellulose acetate filters (Millipore, HAWP02500); the mycelium was then dried at 100°C for dry weight determination. Total actinorhodin was determined by lysing 1 mL aliquots of the culture with 1 M KOH, which were then centrifuged to remove debris and measuring OD_{640} (Kieser et al., 2000).

Experimental Evolution

Spores of *S. coelicolor* M145 were used to inoculate test tubes (16x150 mm) containing 2.5 mL of LB + 25% sucrose, which were incubated with orbital shaking at 30° C. After 48 h of growth, the tubes were left standing without shaking for 10 min to allow most of the mycelial pellets to sediment. Then, the upper 0.2 mL of each culture was transferred to a new tube with fresh medium and incubated as before. The process was repeated every 48 h until the culture consisted of slow sedimenting mycelium which appeared visibly dispersed. When this stage was reached, the mycelium was transferred to MS agar plates and allowed to sporulate. Spores were then streaked onto fresh plates for single colony strain purification. Spores from individual colonies were tested in LB + 25% sucrose, and spore preparations were made of those strains maintaining dispersed morphology after single colony purification.

Microscopy and Pellet Size Determination

Six independent cultures of M145 and 2L12 were grown in non-viscous medium (2xYT), and the morphology of mycelial pellets was analyzed using a Nikon Eclipse 6000 microscope. In order to measure the complete pellets of strain M145, consecutive bright-field images under 10× amplification were taken and stitched together using the ImageJ plugin Stitching (Preibisch et al., 2009) as pellets of the wild type were often too large to fit in a single field. The area of the cross-section of the pellet was measured using ImageJ tools.

DNA Extraction, Genome Sequencing and Mutation Analysis

For total DNA isolation, a modification of procedure 4 of Hopwood et al. (1985) was used. Briefly, 25 mL cultures of strains M145 and 2L12 were grown in LB+25% sucrose medium for 48 h, the mycelium was then harvested by centrifugation, washed with 25 mL of a 10% sucrose solution, and resuspended in 5 mL of lysis

buffer (25 mM Tris–Hcl, 25 mM EDTA, pH = 8.0) containing 5 mg of freshly dissolved lysozyme and 250 μg of RNase A, and incubated at 37 C for 1 h. After lysis, 2.5 mL of a 2% SDS solution was added followed by vortexing for 30 s. The resulting lysed mycelium was extracted several times with an equal volume of saturated phenol:chloroform until a clear interphase was observed after centrifugation. Total DNA was then precipitated with ethanol, dried and resuspended in 0.5 mL of distilled water. The libraries were constructed with a TrueSeq DNA PCR-Free Library Prep kit (Illumina, 215962), and sequenced in an Illumina MiSeq equipment at a 2 × 150 cycles configuration at the Unidad Universitaria de Secuenciación Masiva y Bioinformática of the Universidad Nacional Autónoma de México[1].

For variant calling, pair-end reads were aligned to the reference *S. coelicolor* A3(2) genome (NC_003888.3) using Bowtie 2 software (Langmead and Salzberg, 2012). Variant calling was performed using Samtools (Li, 2011) and VCFtools (Danecek et al., 2011). Only variants with a quality score above 100 were considered, and analyzed individually against the reference genome using Artemis (Carver et al., 2012). Variants present in both M145 and 2L12 were filtered out, as were variants with a lower quality score not present in at least 95% of all individual reads. The bam files used for variant calling, which contain all the sorted and aligned reads, are available from the NCBI with accession no. PRJNA499125.

Sedimentation Time Determination

Spores of the strains to be tested were used to inoculate liquid LB + 25% sucrose medium to obtain dispersed mycelium, which was then used to inoculate 2xYT medium at a 1:20 ratio. Mycelial pellets were cultured for 48 h at 30°C. To measure the sedimentation time of the pellets, cultures were diluted with one volume of water and left to settle at the bottom of the tube before taking 0.5 mL to overlay on top of a 2 cm column of a 10% sucrose solution in a 13 × 100 mm test tube. The time reported in this work is the time it took for the first pellet in each tube to reach the bottom of the solution.

Genetic Manipulation

PCR targeting (Datsenko and Wanner, 2000) was performed as described by Gust et al. (2004). The *aac3(IV)-oriT* (apra) cassette described by Gust et al. (2004), which confers resistance to apramycin, was amplified with oligonucleotides SCO5282For and SCO5282Rev (**Table 1**) and used to replace the *sco5282* gene in cosmid StCB12 (Redenbach et al., 1996). This cosmid (StCB12Δ*sco5282*::apra) was introduced by conjugation from the non-methylating *Escherichia coli* strain ET12567/pUZ8002 (Gust et al., 2004) into the wild type strain M145 to obtain apramycin-resistant exconjugants, which were then tested for kanamycin resistance. A kanamycin sensitive exconjugant was purified and confirmed by PCR as a Δ*sco5282*::apra null mutant (strain IB94). The StCB12Δ*sco5282*::apra cosmid was also used to clone the *sco5282-D125G* allele by introducing it into strain 2L12, and selecting exconjugants resistant to both apramycin and kanamycin, in order to obtain strains with the cosmid inserted into the chromosome. These strains were grown non-selectively in liquid culture, and covalently closed circular DNA was purified, which was then introduced into *E. coli* strain DH5α by transformation, with selection for kanamycin and ampicillin resistance. About half of the colonies were resistant to apramycin and carried the StCB12D*sco5282*::apra cosmid, whereas the other half were apramycin-sensitive and therefore carried the StCB12*sco5282-D125G* allele, which was confirmed by DNA sequencing. The StCB12*sco5282-D125G* cosmid was introduced into strain IB94 to replace the apramycin resistance cassette with the cloned *sco5282-D125G* allele, yielding strain M145*sco5282-D125G*. Allele replacement was confirmed by sequencing the PCR product obtained from chromosomal DNA of the resulting

strain with primers SCO5282Up and SCO5282Down, which flank the kinase gene.

The apramycin resistance gene of strain IB94 was removed by recombination between the FLP sites of the cassette, resulting in a 81 bp non-polar scar sequence (Gust et al., 2004). This apramycin-sensitive Δ*sco5282*::*scar* strain (IB95) was used in subsequent studies. The same procedure was followed to obtain strains lacking both genes for the two-component system, resulting in strains IB96 (Δ*sco5282-sco5283*::apra) and IB97 (Δ*sco5282-sco5283*::*scar*), using primers SCO5283For and SCO5282Rev.

Genetic Complementation

Wild-type and mutant *sco5282* kinase genes were amplified by PCR with *Pfu* Ultra DNA polymerase (Agilent Technologies) from chromosomal DNA of M145 and 2L12, respectively, using primers clSCO5282For and clSCO5282Rev, which add an in-frame NdeI site at the start codon, and an EcoRI site at the 3′ end after the stop codon. The blunt-end PCR products were cloned in plasmid pBlueScript II SK (Alting-Mees and Short, 1989) digested with EcoRV, and their DNA sequence was confirmed using universal M13 primers. The wild type and mutant genes were then subcloned in vector pIJ6902 (Huang et al., 2005) using NdeI and EcoRI, thereby placing them under control of the inducible promoter P_{tipA}. The resulting plasmids were transferred to *S. coelicolor* via conjugation with *E. coli* ET12567/pUZ8002. Sedimentation times of the mycelial pellets of the complemented strains were measured in the absence of thiostrepton.

Merodiploid Strains

The ampicillin-resistance gene of cosmids StCB12 and StCB12*sco5282-D125G* were replaced by PCR targeting with the apramycin-resistance cassette from pIJ784 bearing the origin of transfer *oriT* (Gust et al., 2004), so that they could be introduced to *Streptomyces* by conjugation. Exconjugants for each cosmid were selected and maintained in the presence of both kanamycin and apramycin, to select for the presence of the integrated cosmids. Sedimentation times of the mycelial pellets grown in the presence of 25 μg/mL kanamycin were determined as described above.

Phosphorylation Assays

The *sco5283* gene coding for the response regulator was amplified by PCR with primers clSCO5283for and clSCO5283rev (**Table 1**) and cloned in pET28a using the NdeI and EcoRI sites. The region encoding the cytosolic domain of the wild type and mutant sensor kinases (amino acids 80-375), were amplified by PCR from the wild type *sco5282* and mutant *sco5282-D125G* genes, respectively, with primers clSCO5282sol and clSCO5282rev (**Table 1**) and also cloned in pET28a with NdeI and EcoRI. The plasmids were then introduced into *E. coli* Rosetta 2 (Novagen) for protein expression. Protein purification was carried out using a Ni-NTA Superflow Cartridge (QIAGEN, 30721) in an FPLC system (ÄKTAprime plus; GE Healthcare) according to the manufacturer instructions.

Autophosphorylation and transphosphorylation assays were performed as described by Álvarez and Georgellis (2012).

RNA Extraction, Sequencing and Analysis

For RNA extraction, three independent cultures of strains IB97 and M145-D125G were grown in 2xYT medium until mid-log phase (24 h), in shaking flasks without coils to allow pellet formation. Mycelium was harvested by filtration as described in Hopwood et al. (1985) and RNA isolation was carried out as described in Kieser et al. (2000), but using a modified Kirby mixture (1% SDS, 6% EDTA, 6% saturated phenol solution, 150 mM β-mercaptoethanol, 50 mM Tris–Hcl, pH = 8.3) as follows: pellets were filtered through ice-cold Whatman paper after pouring the cultures over a funnel containing ice, placed above the filter; the filter was washed with ice-cold water and the mycelium was then scraped into ice-cold modified Kirby solution and vortexed with an equal volume of 4 mm glass beads for 2 min, then five pulses of 30 s. The suspension was extracted with equal volumes of phenol:chloroform until the interphase was clear, then precipitated with sodium acetate and isopropanol. Total nucleic acids were treated with RNAse-free DNAse I (Ambion, AM2222; Thermo Fisher Scientific) until no PCR product was detected after 30 cycles using primers ATTB_FOR and ATTB_REV (**Table 1**). rRNA was depleted by subtractive hybridization with the Ribo-Zero Gram-positive kit (Illumina, MRZGP126); mRNA libraries for each of the three independent cultures of each strain were constructed using the TrueSeq stranded mRNA Library Prep kit (Illumina 20020594) and sequenced in an Illumina NextSeq 500 equipment, with up to 10^7 paired reads/sample. Raw RNA sequencing reads are available through the NCBI Sequence Read Archive (BioProject Accession No. PRJNA499125).

Sequences were mapped to the reference genome of *S. coelicolor* A3(2) (NC_003888.3) and differential expression evaluated with packages DESeq2 1.18.1 (Love et al., 2014), edgeR 3.20.9 (Robinson et al., 2010) and NOISeq 2.22.1 (Tarazona et al., 2011). Genes were considered differentially expressed if they showed a $\log_2$ fold-change above 1 and an FDR-controlled *p*-value below 0.05. Genes that resulted positive with at least two tests were annotated with eggNOG-mapper (Huerta-Cepas et al., 2017).

RT-qPCRs to Validate Differential Gene Expression

RNA obtained as described before was used in RT-qPCR using the Luna Universal One-Step RT-qPCR kit (NEB, E3005S), following the manufacturer's instructions with 100 ng total RNA/reaction plus 5% DMSO (NEB, B0515). Differential expression was calculated according to the ΔΔCt method (Livak and Schmittgen, 2001), using the *hrdB* gene as calibrator. Primers used are listed in **Table 1**.

Statistical Analysis

Pellet size and differential gene expression were compared by Student's *t*-test. Due to the asymmetrical distribution of the sedimentation time, the corresponding assays were analyzed by the non-parametric Kruskal-Wallis test for multiple comparisons, with *post hoc* Dunn test with Benjamini-Hochberg

correction of experiment-wise error rate. Statistical significance was determined at p-value < 0.05. All statistical procedures were performed using R version 3.4.4 (R Core Team, 2018).

RESULTS

Experimental Evolution for Selection of Slow-Sedimenting Strains

Since wild type *S. coelicolor* grows in liquid medium as tight, dense mycelial pellets that settle quickly when the culture is left without shaking, we sought to isolate mutants showing dispersed growth by adapting a gravity-based sedimentation strategy used previously by Ratcliff et al. (2012). Our strategy consisted of sequentially transferring the uppermost part of settled cultures for reinoculation, as opposed to the strategy used to isolate multicellular derivatives of *S. cerevisiae*, which consisted of sequentially transferring the lower part of the settled cultures. Thus, any mutation which allowed for more dispersed mycelium and less dense mycelial pellets would be positively selected. By applying this selection to independent cultures of the wild type M145 strain, we observed more dispersed morphologies appearing after 12–56 transfers. The different isolates were transferred to solid medium and purified from single colonies after one sporulation round. Most of the purified strains no longer showed dispersed growth in liquid medium, or showed increased antibiotic production and reduced spore viability and were no longer considered. Only one strain, which was named 2L12, was phenotypically indistinguishable from M145 on solid MS medium and retained the slower sedimenting, dispersed growth phenotype when reinoculated in liquid medium.

Microscopically, the main difference between strain 2L12 and the parental strain M145 was the pellet size when both were grown in liquid media without sucrose (**Figure 1**). The pellets of 2L12 were smaller, like the one shown in **Figure 1** (with an area of 0.242 mm^2), and frequently appeared breaking apart, suggesting increased fragility. Pellets of the wild type M145 frequently reached at least the size of the pellet shown in **Figure 1** (with an area of 0.621 mm^2). It is worth noting that, under these conditions, we never found in the 2L12 strain a pellet of the size depicted for M145, whereas on almost every experiment the wild type pellets reached at least this size (**Supplementary Table S1**) The growth rate of 2L12 was indistinguishable from that of M145, either in liquid YEME medium with 34% sucrose or in 2xYT medium (**Figures 2A,B**), indicating that the reduced pellet size was not due to a major growth defect.

In order to have an objective way to compare the phenotypes of the M145 and 2L12 strains, we measured the time it took for the pellets of either strain to settle through a 2 cm high column of a 10% sucrose solution in a 1 cm wide test tube, since loose and smaller pellets would take longer to settle to the bottom of the tube because of their lower density. As expected, the selected

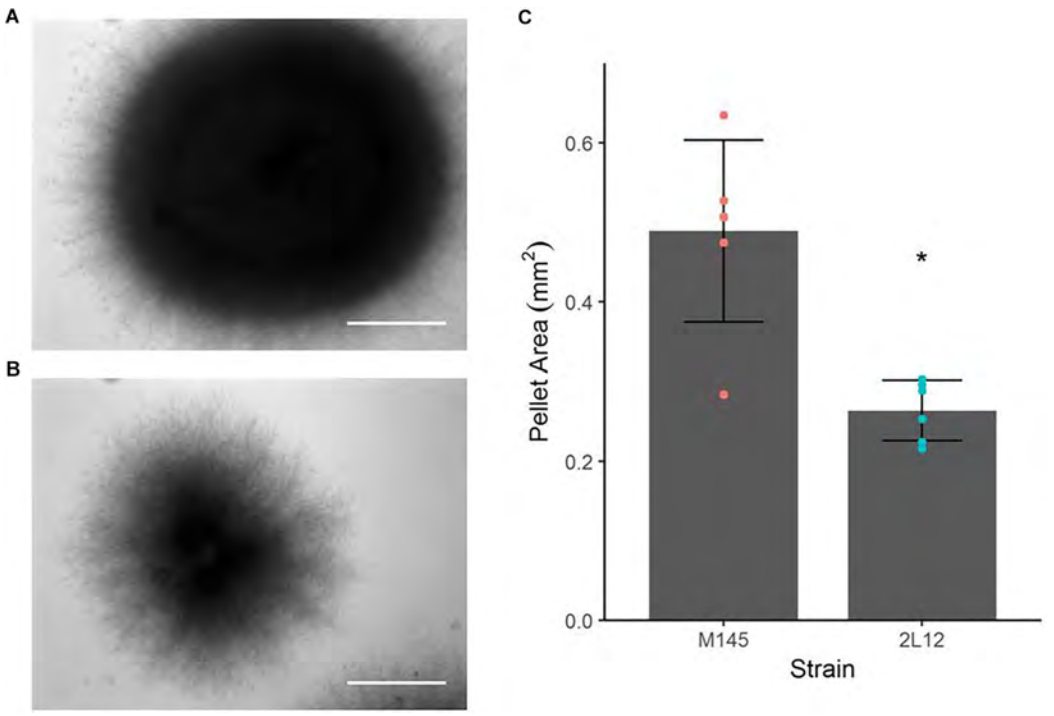

FIGURE 1 | Pellet morphology of strains M145 and 2L12. Bright field microscopy of representative pellets, grown in 2xYT medium. **(A)** M145 pellet with an area of 0.621 mm^2 and **(B)** 2L12 pellet with an area of 0.242 mm^2. These areas are around the average of the distribution for each strain. It is worth noting that under these conditions, no pellets were found in the 2L12 strain of the size shown for M145, whereas in almost every experiment the M145 pellets reached at least this size. The scale bar corresponds to 0.2 mm. **(C)** Pellet area quantification. Each dot represents the average area of pellets from an independent culture; the raw data for each independent culture are shown in **Supplementary Table S1**. Bars represent mean ± standard deviation. An asterisk indicates significant difference at $p < 0.01$.

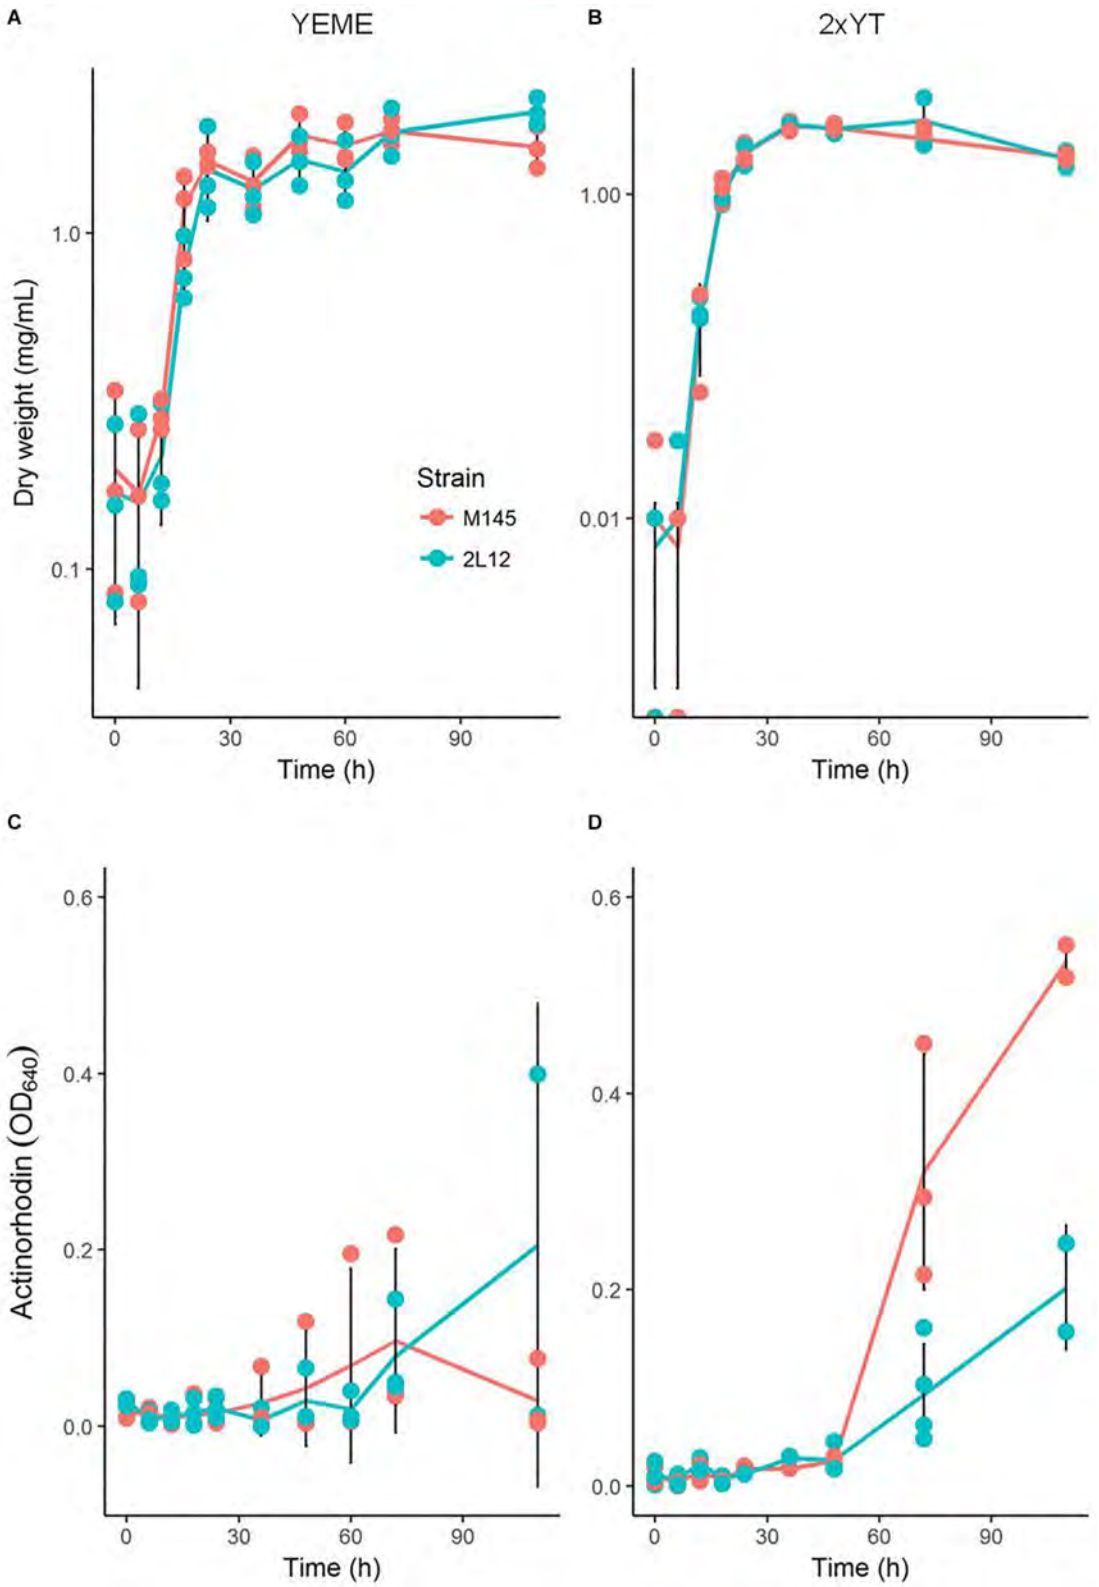

FIGURE 2 | Growth and actinorhodin production by M145 and 2L12 strains. **(A,B)** show the growth curves in YEME and 2xYT media, respectively; **(C,D)** show actinorhodin production in YEME and 2xYT media. Each dot represents a measurement from each of three independent cultures; black vertical lines represent the means ± standard deviation.

2L12 strain settled significantly slower to the bottom of the tube than the M145 wild type strain (**Figure 3**), confirming the validity of our experimental evolution strategy (i.e., slower sedimentation due to increased mycelial dispersion).

We also measured total actinorhodin production of both strains grown in liquid media. In YEME, where neither strain forms large pellets due to the increased viscosity caused by the 34% sucrose present in the medium, there was no significant difference in actinorhodin production (**Figure 2C**). On the other hand, in 2xYT, where the wild type strain forms large, dense, pellets, only M145 produced actinorhodin (**Figure 2D**). This is consistent with previous studies which showed that most antibiotic production takes place inside pellets (Manteca et al., 2008). Together, these results demonstrate that, although strain 2L12 produces less actinorhodin under this condition, this difference is due to its morphology and is not caused by a mutation specifically affecting synthesis of this antibiotic.

A Single Amino Acid Substitution Is Responsible for the Dispersed Growth Phenotype of Strain 2L12

In order to determine the genetic change responsible for the phenotype of 2L12, we sequenced the genome of this strain and also the genome of the isogenic M145 wild-type strain, grown from the same spore vial used for the evolution experiment that led to isolation of 2L12. After variant calling and filtering, a single nucleotide change, a T to C transition in nucleotide 5,754,703 of the *S. coelicolor* genome sequence (GenBank accession NC_003888) appeared as the likely mutation responsible for the differences observed between both strains (**Supplementary Table S2**). This mutation lies in the *sco5282* gene, which encodes a histidine kinase of a two-component system of unknown function. This kinase gene is translationally coupled to an upstream gene, *sco5283*, which encodes an OmpR-type response regulator. The Sco5282 kinase is predicted to be membrane-anchored by two transmembrane domains, followed by a cytosol located HAMP domain, which functions as a signal transmitter domain in many two-component sensor kinases (Parkinson, 2010). The HAMP domain is followed by the histidine kinase (HisKA) domain and a C-terminal HATPase domain (**Figure 3A**). The mutation found in 2L12 causes a substitution of an aspartate to a glycine (D125G) in the second helix of the HAMP domain of the kinase (herein referred to as *sco5282-D125G*). Analysis of the variants between genome sequences revealed two other possible mutations: one inside the *sco4820* gene and the other one in the intergenic region between *sco6571* and *sco6572*. However, these variants had much lower quality scores (179 and 160, vs. 222 of *sco5282-D125G*) and, in the case of the variant in the *sco4820* gene, not all the

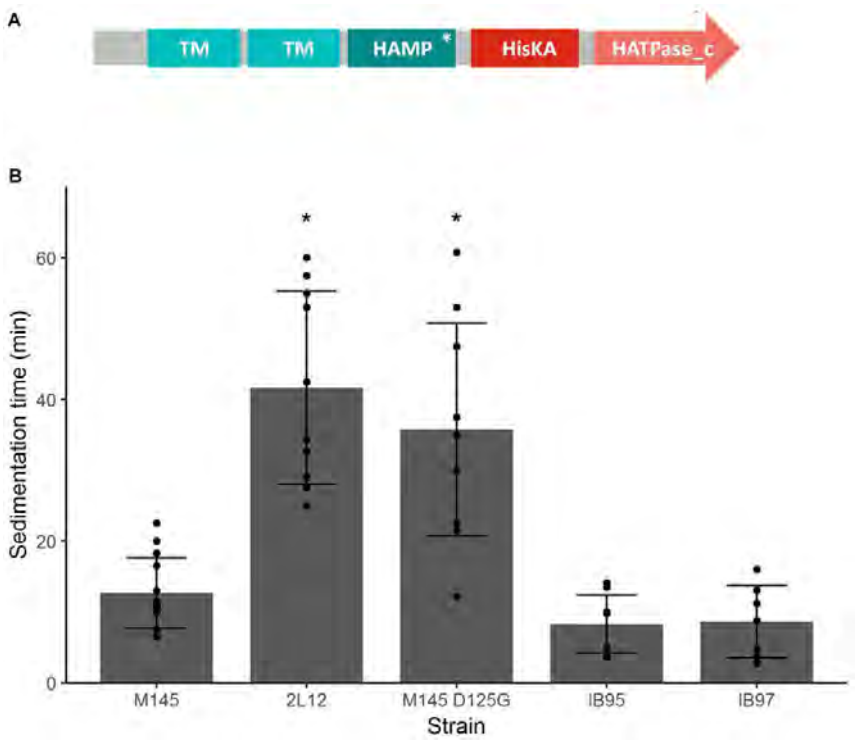

FIGURE 3 | (A) Domain structure of the Sco5282 histidine kinase. TM, transmembrane domain; HAMP, HAMP domain; HisKA, histidine kinase domain, HATPase_c; ATPase domain. An asterisk shows the position of the D125G mutation. **(B)** Sedimentation time of *sco5282* mutants. Spores were germinated in viscous medium, then grown in thin medium. Pellets were deposited on top of a 2 cm tall 10% sucrose solution, and the time it took for the first pellet to reach the bottom of the tube was measured. Each dot represents the measurement from an independent culture; bars show the mean ± standard deviation; asterisks indicate statistical significance ($p < 0.01$).

aligned reads showed the presence of this putative mutation, as opposed to *sco5282-D125G* where the mutation was present in all the aligned reads (**Supplementary Table S2**). For this reason, we focused on the mutation in the *sco5282* gene. Interestingly, when the presence of Sco5282/Sco5283 orthologs was analyzed by reciprocal BLASTP searches using the Actinoblast database (Chandra and Chater, 2014[2]) this two-component system was found to be prevalent in the *Streptomycineae*, but not in other actinomycetes suborders (**Supplementary Figure S1**).

To demonstrate that the *sco5282-D125G* allele was responsible for the phenotype of strain 2L12, we transferred it to the wild type M145 background by recombining this mutation *in vivo*, using the StCB12 cosmid (which carries the *sco5282* and *sco5283* genes) as described in Materials and Methods. This resulting strain, M145*sco5282-D125G*, was grown in liquid culture and its sedimentation time was measured. It was found that this strain had the same slow-sedimentation phenotype as the 2L12 strain, demonstrating that the mutation in the histidine kinase gene *sco5282* is sufficient to cause a dispersed, slow-sedimenting morphology (**Figure 3B**). We also constructed a mutant carrying an in-frame deletion of the *sco5282* gene, IB95, and a mutant lacking both the kinase and response regulator genes (Δ*sco5282-5283*), IB97, and tested their sedimentation time. Interestingly, a wild-type phenotype, with fast sedimentation times was obtained for both the IB95 and IB97 mutant strains (**Figure 3B**). This result suggested that the *sco5282-D125G* allele is a gain-of-function mutation. It also implies that, during normal growth this two-component system is most likely inactive, since the absence of the Sco5282 kinase resulted in wild-type growth. To confirm that the *sco5282-D125G* allele is responsible for the dispersed morphology phenotype, we cloned the mutant allele under the control of the P_{tipA} promoter in the integrative expression vector pIJ6902, and introduced it into strain IB95, to complement the Δ*sco5282* null mutation. As can be seen in **Figure 4**, expression *in trans* of the mutant allele restored the dispersed growth phenotype, even without adding thiostrepton as inducer. This indicates that the mutant *sco5282-D125G* allele is able to produce a dispersed morphology even when it is expressed at the low constitutive level observed for the P_{tipA} promoter in the absence of thiostrepton (Ali et al., 2002). When the same plasmid was introduced into strain IB97, the mutant kinase alone did not cause the slow-sedimenting phenotype (**Figure 4**), indicating that the Sco5282-D125G mutant kinase exerts its effect through the Sco5283 cognate response regulator.

The D125G Mutation Is Recessive

Since the *sco5282-D125G* allele appeared to be a gain of function mutation, we decided to determine whether it was dominant over the wild type gene. To this end, we introduced the pIJ6902 plasmid derivative carrying the mutant *sco5282-D125G* allele into the wild type M145 strain. Surprisingly, the mutant allele did not promote dispersed growth in the presence of the wild type gene (**Figure 4**) and therefore appeared to be recessive. To confirm this, we constructed merodiploid strains by inserting either the wild type StCB12 or the mutant StCB12*sco5282-D125G* cosmids into both the M145 and 2L12 strains, through homologous recombination. In this way, two copies of the two-component system, each one expressed from its own promoter, could be

[2]http://streptomyces.org.uk/actinoblast

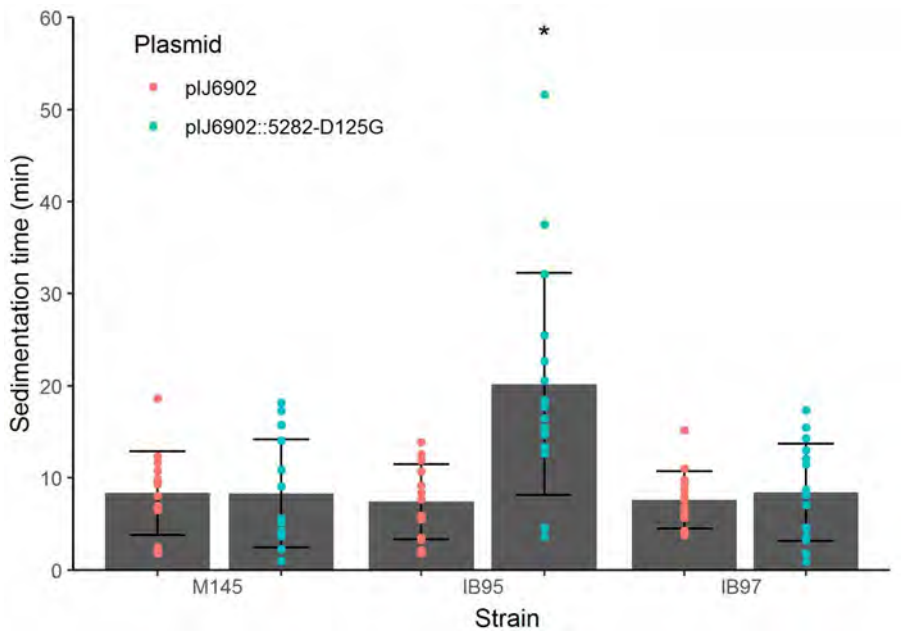

FIGURE 4 | Sedimentation times of complemented strains. Vector pIJ6902 was introduced either empty or with the cloned *sco5282-D125G* gene into the indicated strains. Each dot represents the measurement from an independent culture; bars show the mean ± standard deviation; an asterisk indicates statistical significance ($p < 0.01$).

tested in the proper homozygous or heterozygous combinations. Measuring the sedimentation time of these strains revealed that insertion of a wild-type cosmid in strain 2L12 resulted in a wild-type phenotype, whereas insertion of the D125G cosmid did not result in a dispersed-growth phenotype in M145 (**Figure 5**). Both wild-type and mutant cosmids were also introduced into strain IB97, resulting in wild-type and mutant phenotypes, respectively (**Figure 5**). Taken together these results confirm that the *sco5282-D125G* mutation is recessive and also rule out the possibility that doubling the gene dose of the neighbor genes which are present in the cosmid might affect the growth phenotype.

The D125G Substitution in the HAMP Domain Results in Activation of the Sco5282 Kinase

As mentioned above, the D^{125} to G mutation in Sco5282 appears to result in enhanced phosphorylation of the Sco5282/Sco5283 two-component system. To test this, His_6-tagged versions of the Sco5283 protein and also of the cytosolic portions of the wild-type and mutant Sco5282 proteins were overexpressed in *E. coli*, purified by Ni-NTA-agarose affinity chromatography and used in *in vitro* autophosphorylation and transphosphorylation assays with [γ-^{32}P]ATP (**Figure 6**). Although both the wild type and the mutant kinase proteins had similar kinetics regarding their autophosphorylation, the mutant Sco5282-D125G kinase exhibited a significantly higher transphosphorylation rate of the Sco5283 response regulator as compared to the wild type Sco5282 kinase protein. Net phosphorylation of Sco5282-D125G was also higher in the presence of Sco5283 as compared to Sco5282. Thus the D125G substitution in the Sco5282 kinase appears to be an activating mutation.

Transcriptomic Differences Between Dispersed and Pelleting Strains

Since strain 2L12 is carrying an activating mutation in the Sco5282/Sco5283 two-component system, it is reasonable to argue that its dispersed growth is caused by the activation of genes that are normally not expressed or that have a low expression level. To investigate which genes were affected, we decided to analyze the transcriptomes of a strain with wild-type morphology and one with dispersed morphology. In order to maximize the differences in expression of target genes of the two-component system, we chose the strain M145*sco5282-D125G* as the strain exhibiting dispersed slow-sedimenting growth, and IB97 (i.e., the null Δ*sco5282-5283* mutant) as the tightly pelleting fast-sedimenting strain. Total RNA was extracted from three independent cultures of each strain at mid-log phase grown in 2xYT, the medium where morphological differences are maximal. After rRNA subtraction the samples were sequenced and gene abundances were compared using three statistical packages: DESeq2 (Love et al., 2014), edgeR (Robinson et al., 2010) and NOISeq (Tarazona et al., 2011). Comparisons were made between M145*sco5282-D125G* and IB97, so that positive $\log_2$ Fold Change represents genes that were either highly overexpressed in the dispersed strain, or repressed in the pelleting strain. 437 genes were found to be differentially expressed, and 354 of them were identified by all three statistical tests. Genes

identified by at least two tests were annotated with the program eggNOG-mapper (Huerta-Cepas et al., 2017) to assign functional categories (**Figure 7**). Differential expression of relevant genes mentioned in the sections below and shown in **Tables 2–4**, was validated by qPCR as described in "Materials and Methods," and shown in **Table 5**. A table showing the differentially expressed genes identified by all three statistical packages is provided as **Supplementary Table S4**.

Genes Involved in Envelope Maintenance

Among the most overexpressed genes in the dispersed M145*sco5282-D125G* strain were many involved in protein secretion and envelope maintenance (**Table 2**). The single most overexpressed gene was *sco0753* which encodes a 77 amino acid peptide of unknown function. This gene is located upstream of an operon for a secretion system (*sco0754-sco0756*), homologous to a type I secretion system and similar to bacteriocin secretion systems (Håvarstein et al., 1995). The Sco0753 peptide has been predicted as a probable bacteriocin-like ribosomal lanthipeptide (van Keulen and Dyson, 2014). It is predicted to be very hydrophobic (57% of hydrophobic amino acids) reminiscent of the hydrophobic proteins that coat the hyphae during differentiation helping them to break free from the aqueous medium (Flärdh and Buttner, 2009). The fact that these four genes are conserved in many *Streptomyces* species, with the same genomic organization, suggests that this hydrophobic peptide is exported by the above mentioned secretion system.

Another gene with upregulated expression in the dispersed strain was *mbl2* (*sco6166*), which encodes one of the three MreB homologs present in *S. coelicolor*. Previous studies have shown that *mbl2* was expressed only in vegetative mycelium and repressed during differentiation (Heichlinger et al., 2011), in contrast to the other two paralogs, MreB and Mbl1, which were found to regulate cell wall deposition during sporogenic cell division, with a similar role to the one played by homologous proteins in unicellular bacteria.

The Sec system component SecDF (*sco6160*) was also greatly overexpressed in the dispersed strain. This protein consists of domains paralogous to SecD and SecF, but fused into a single

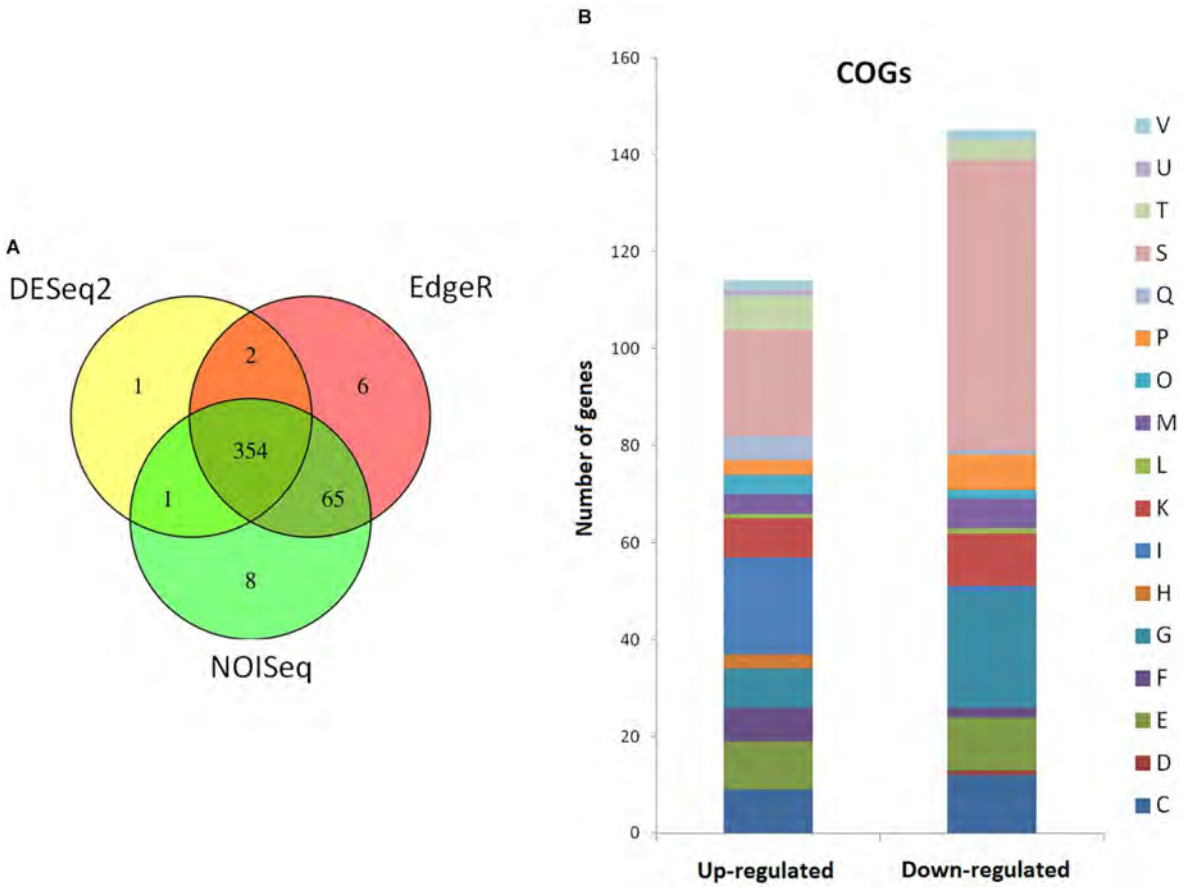

FIGURE 7 | Summary of the differentially expressed genes. **(A)** Venn diagram showing the number of differentially expressed genes as analyzed by the statistical analysis packages DESeq2, EdgeR, and NOISeq. **(B)** Cluster of orthologous groups (COG) annotation of RNAseq-identified differentially expressed genes. polypeptide, which is normally expressed at very low levels (Zhou et al., 2014). It appears to be part of an operon which includes a two-component system, since all these genes had similar expression levels. SecDF promotes the release of secreting polypeptides, providing the proton motive force and enhancing protein secretion (Tsukazaki et al., 2011). This suggests that the dispersed strain is dealing with protein secretion stress, although it is not yet possible to tell whether this is a cause or a consequence of the mutant morphology.

On the other hand, exopolysaccharide synthesis proteins were repressed in the dispersed-growing strain. Of special interest is the gene encoding the MatB protein (*sco2962*), whose absence is known to lead to mycelial dispersion (van Dissel et al., 2015). However, the upstream gene, *matA*, was not differentially expressed. Further analysis is required to determine whether these genes are transcribed as a single unit, and in that case, the mechanism by which the system Sco5282-Sco5283 could be affecting such differential regulation. Even though *cslA* and *glxA* were not part of the set of genes identified by all three statistical analysis packages as differently expressed, their expression levels were lower in the dispersed mutant, and in the case of *cslA* this reduced expression was found to be statistically significant by two of the packages (see **Supplementary Table S3**).

Primary Metabolism Genes

A majority of the genes identified as differentially expressed were annotated in the primary metabolism category. This was not surprising, since pellet formation is known to exert stress on the cells and limit the amount of oxygen and nutrients available to hyphae. Therefore, cell metabolism must adapt to the different conditions imposed by the morphology.

The main metabolic routes affected were those for branched-chain amino acids and purine degradation, which were stimulated in the dispersed strain, along with the regulatory enzymes of gluconeogenesis (**Table 3**). Glycolysis, on the contrary, was repressed in this strain. Together, these findings suggest that strain M145 *sco5282-D125G* is taking up carbon from amino acids and purines, the main components of 2xYT

medium, while the pelleting IB97 strain is using carbohydrates. Most likely this is a consequence of the lysis occurring inside the pellets, which releases murein for the growing hyphae to feed on.

It is noteworthy that the genes for glyceraldehyde-3-phosphate dehydrogenase, for which *S. coelicolor* has three copies, were all differentially expressed. Two of them, including the most important *gap* gene during vegetative growth (*sco1947*, Li and Townsend, 2006) were repressed in the dispersed strain, while *sco7040* was overexpressed. This suggests specialized functions for the enzyme encoded by each gene, that may be related to their role in glycolysis and gluconeogenesis.

Other genes, strongly repressed in the dispersed strain, are those of the pentose-phosphate pathway.

Regulatory Genes

The genes for 24 transcriptional regulators were found to be differentially expressed. Of those with known function, regulators of stress responses that indirectly promote differentiation and sporulation stand out. For example, SigB (*sco0600*) is an osmotic stress response sigma factor (Cho et al., 2001), which promotes differentiation by activating SigM (*sco7314*, Lee et al., 2005) and its own anti-anti-sigma factor RsbV (*sco4005*, Lee et al., 2004). Although SigK is a negative regulator of sporulation, its transcript is accumulated at the onset of the differentiation process (Mao et al., 2009). RamR is an orphan response regulator which also promotes sporulation indirectly (Keijser et al., 2002). All of these stress-response sporulation-promoting genes are overexpressed in the pelleting IB97 strain (**Table 4**), in agreement with previous knowledge that tight clumping induces stress in the mycelium.

No direct regulators of sporulation were identified, with the exception of WhiD, a regulator required for sporulation that normally is not expressed in liquid media, where no sporulation takes place (Molle et al., 2000). Nevertheless, this regulator was overexpressed in the dispersed mutant (**Table 4**), opposite to the trend of the indirect sporulation regulators. It has to be mentioned that little is known about

the role of WhiD, other than the fact that it possesses a [4Fe-4S] nucleus capable of binding oxygen and nitric oxide (Jakimowicz et al., 2005; Crack et al., 2009).

Recently, it has been revealed that cytosolic copper is a major modulator of germination and development in *S. coelicolor*, and that its levels depend on the copper export system, encoded by the *sco2730* and *sco2731* genes. As is shown in **Supplementary Table S3**, no significant differences in the expression of these genes was observed in the dispersed mutant.

No regulators of antibiotic biosynthesis were differentially expressed, which is probably due to the fact that the RNA samples were taken at mid-log phase, when there is no antibiotic biosynthesis.

Gas Vesicles

Among the most differentially expressed genes was one of the two clusters of gas vesicle genes in the *S. coelicolor* genome (genes *sco6499-sco6508*). Despite being widespread among actinobacteria, there are no reports of functional gas vesicles in these organisms (van Keulen et al., 2005). Transcriptional activation of this cluster has been seen in mutants of the arginine-synthesis regulator gene *argR* (Botas et al., 2018), of the nitrogen sensor *glnK* (Waldvogel et al., 2011), in response to saline stress, in a SigB dependent manner (Lee et al., 2005) and in the presence of antibiotics that target cell wall biosynthesis (Hesketh et al., 2011). These genes were greatly overexpressed in strain IB97, suggesting that their expression might be related to the general stress response shown by this strain.

DISCUSSION

In this study, we set up an experimental approach to focus on the factors governing mycelial aggregation in liquid culture. By working with liquid *S. coelicolor* cultures, it is possible to restrict the phenomenon to the non-sporulating vegetative mycelium. By applying a very general selective pressure, as is sedimentation speed, it was possible to isolate many

different slow-sedimenting strains with dispersed morphology. Even though none of them reached a level of dispersion or fragmentation like the one seen in *S. venezuelae*, the fact that several different mutational events could be found, even in such a relatively short time (12 transfers), indicates that submerged culture morphology is a multifactorial trait that can be affected through many different ways. Initial concerns that too many mutations could arise in such experiments, complicating further analysis, were dissipated upon discovery that few generations were needed to obtain a visibly distinct phenotype, given that many different independent cultures were set up since the beginning. Strain 2L12 appeared on the 12th transfer, the fastest of all cultures used in this study, and it is most likely because of this that it differed from the wild type strain by a single point mutation.

It was important to identify mutations that did not have pleiotropic effects that could be causing fragmentation as a secondary effect to other major metabolic changes or that showed altered viability or differentiation. In this regard, we chose to work with strain 2L12 because it did not have any differentiation or sporulation problems. Even more so, growth kinetics showed that it was indistinguishable from wild-type M145, proving that it had no major defects in primary metabolism. It was surprising to find that in medium without sucrose, where morphological differences are the most pronounced between the two strains, growth proceeded at exactly the same rate, since pelleted forms are known to show reduced growth (Walisko et al., 2015). Nevertheless, it has been reported previously that those differences are especially seen in bioreactors, and not in cultures grown in shake flasks (van Dissel et al., 2015).

Metabolic adaptations were expected to take place in order to compensate for the different morphologies. Indeed, a third of the functional categories assigned to the differentially expressed genes belong to primary metabolism (**Figure 7**). Thus, the two different strains were on two different metabolic states despite growing at the same rate: the slow-sedimenting dispersed strain was using the carbon source in the medium through gluconeogenesis, whereas the fast-sedimenting tight-pelleting strain was using carbohydrates. This difference is probably due to the increased lysis that the pelleting strain is going through, since it has a larger proportion of hyphae inside the pellets, which is where lysis takes place (Manteca et al., 2008). Nonetheless, the pellets continue to grow (Manteca et al., 2008), which is the reason that they reach the same final biomass (**Figure 2A**).

An Activating Mutation in the HAMP Domain

Genome sequencing revealed that strain 2L12 had a single point mutation that caused a substitution of an aspartate residue for a glycine in the HAMP domain of a histidine kinase of a two-component system of unknown function. Transferring the mutant allele to a wild-type background demonstrated that this mutation was sufficient to confer the dispersed slow-sedimenting phenotype. Further genetic analysis showed that this is not a loss-of-function mutation, that it does not change the specificity of the kinase for its cognate response regulator, and that it is a recessive allele. These are interesting findings for a HAMP domain mutation. The HAMP domain is composed of two helices, AS1 and AS2 that form a 4 helix-bundle when the kinase dimerizes. A phase-stutter at the contact of the helices allows them to rotate upon detection of the signal (Parkinson, 2010). Aspartate 125 is located in the membrane-distal part of the AS2 helix, opposite to the contact side of the helices, suggesting that it is probably not directly involved in the conformational changes of signal transmission.

Nevertheless, a substitution for a glycine is likely to interrupt the helical structure. Previously, destabilizing mutations in the membrane-distal half of the AS1 helix were identified as activating mutations of the PhoQ kinase (Matamouros et al., 2015). A model was proposed in which interactions between the HAMP and catalytic domains repress kinase activity. Extracellular signaling would disrupt these interactions, leading to kinase activation (Matamouros et al., 2015). Therefore, destabilizing mutations in the HAMP domain could lead to increased kinase activity. In this work, a similar mutation was found in the AS2 helix, with the same activating effect. Even though *in vitro* autophosphorylation was almost identical between the wild-type Sco5282 and Sco5282-D125G kinases, transphosphorylation of the response regulator by Sco5282-D125G was greatly increased, with a maximal phosphorylation level of the target almost twice that of the wild type. A possibility could be that the equilibrium between phosphorylation and dephosphorylation in the mutant kinase is displaced toward phosphorylation, resulting in increased activation *in vivo*.

This model could also explain why the activating D125G mutation is recessive. The HAMP domain is where the kinase dimerizes. In a heterozygous cell, both wild-type and mutant monomers are produced, which entails formation of heterodimers. These molecules would have one destabilized HAMP domain and one functional, which may still interact with the catalytic domain and repress it. Thus, heterodimers would display wild-type transphosphorylation activity, and consequently a wild-type phenotype.

Transcriptional Changes Related to the Dispersed Morphology

Streptomyces morphology is a complex trait. Even though all species have a common life cycle in the soil, growing as a multicellular vegetative mycelium, their growth in the laboratory reveals widely different morphologies. *S. venezuelae* and *S. coelicolor* can form similar vegetative mycelia on solid medium, and yet they represent opposite sides of the morphology spectrum in liquid media: the first grows as fragmented, separate hyphae, while mycelium of the latter becomes inextricably matted in giant nets (van Dissel et al., 2014), which results in formation of large, dense pellets. Many parallels have been drawn between pelleted growth and biofilm formation: like a biofilm, a pellet's matrix is composed of different polymers, at least extracellular DNA and polysaccharides (Xu et al., 2008). Polysaccharides are produced in germinating hyphal tips, to allow adhesion to the substrate and to each other (Zacchetti et al., 2016). Most surprisingly, when faced with nutrient scarcity, pellets disassemble, like a starving biofilm (Zacchetti et al., 2018).

Perhaps because most morphological studies of this genus have focused on sporulation, the part of the life cycle that occurs outside of the substrate, little is known about the importance of hyphal aggregation and biofilm-like mycelial growth. Some components of this extracellular matrix, however, are already known to be important in the *Streptomyces* life cycle: the polysaccharide synthesized by CslA is necessary to guide the hydrophobic chaplin layer that allows aerial hyphae to erect out of the water (de Jong et al., 2009). The other polysaccharide known to be a part of the *Streptomyces* extracellular matrix, synthesized by MatAB, seems to be non-essential for surface growth (van Dissel et al., 2015). Of course, nothing is known about the timing and regulation of these events.

The phenotype of strain 2L12 could be explained by the reduced expression observed in the *matB* gene, whose deletion is known to be sufficient to obtain dispersed growth. This is an important finding, since the Sco5282/Sco5283 two-component system would be the first identified regulator which affects expression of these exopolysaccharide synthases. Since *clsA* and *glxA* expression is also reduced, it is likely that reduced aggregation caused by lower expression of these genes also contributes to the phenotype. Even, though there is reduced expression of *matB,* the expression of the upstream *matA* gene is not altered, suggesting that changes in *matB* expression are most likely not caused by direct regulation by Sco5283. Therefore it appears it is more probable that reduced expression of *matB* is an indirect effect, probably exerted by one of the 24 transcriptional regulators identified as differentially expressed (**Figure 7**), 16 of which have no known targets. Further indication that *matAB* is not part of the direct regulon of Sco5282/Sco5283 is its narrow distribution among *Streptomyces* species: whereas *matAB* is lacking in some species like *S. venezuelae*, *sco5282-sco5283* has orthologs in all *Streptomyces* genomes present in StrepDB (Chandra and Chater, 2014).

Other genes identified as differentially expressed are more likely to be direct targets of the Sco5282-Sc05283 system. The lantibiotic-like peptide Sco0753 was the single most overexpressed gene in the strain carrying the activating Sco5282-D125G allele, with over 60-fold overexpression. Together with its putative secretion system encoded downstream, these genes were almost completely silent in the null mutant. *S. coelicolor* is known to produce another lantibiotic-like peptide

with morphogenic properties, SapB, which is a surfactant peptide required for aerial mycelium erection in some conditions (Willey et al., 2006). It is possible that the Sco0753 peptide could induce changes in the surface of hyphae, although it is unlikely to function exactly as SapB, since it has no cysteins, which lantibiotics require to be processed (Sahl and Bierbaum, 1998).

Another morphogenic protein identified as differentially expressed was the MreB paralog Mbl2. Of the three paralogs encoded in the *S. coelicolor* genome, Mbl2 seems to be expressed exclusively in the vegetative mycelium and its deletion does not affect sporulation in solid medium (Heichlinger et al., 2011). Given the role of MreB coordinating synthesis of the cell wall, it is an obvious candidate to contribute to the alterations observed in strain 2L12.

Other genes differentially expressed suggest an activated protein secretion stress response. SecDF, which is normally not expressed, was activated in the presence of the constitutive kinase. It is interesting that a previous study considered the two-component system Sco5282-Sco5283 as a candidate homolog of *Bacillus subtilis* CssRS, which responds to the Sec secretion pathway stress. It was dismissed because its transcript levels remained unchanged after induction of protein secretion stress (Gullón et al., 2012), although that does not disprove the possibility that it may act as a sensor in this route. Sco5282 has only four amino acids in its extracellular loop, leaving the transmembrane helices as the only regions that could act as a sensor domain, for example to detect stalled Sec complexes. Curiously, among the overexpressed genes in our RNA-seq experiment, there was a serine protease, Sco1741, like the HtrA-like proteases of the CssRS response (Gullón et al., 2012). Protein secretion rate is bound to affect cell envelope structure, since it controls the rate at which remodeling enzymes can be translocated. Thus, strain 2L12 could have a weaker extracellular matrix due to improved secretion of polysaccharide-degrading enzymes.

Further research will be needed to discern the role of these proteins in vegetative mycelium morphology.

In general, our study provides insight into the molecular adaptations to morphological constraints. Most transcriptomic studies are performed in viscous media, where *Streptomyces* forms few or small pellets. In our experiment, RNA samples were specifically taken from 2xYT, a medium that promotes pellet formation, so that the main difference between strains was the pellet size. It is interesting that our results provide further confirmation that pelleted growth induces stress in the cells, as seen by the activation of many stress sigma factors in the null mutant. Surprisingly, gas vesicle genes were also activated in this condition. This cluster had been seen to be activated upon saline stress, in a SigB-dependent manner. SigB is also activated during pelleted growth, suggesting that it may also be regulating gas vesicle genes in this condition, which is unrelated to saline stress. A simple explanation could be that inner hyphae are lacking oxygen, and gas vesicles are formed in an attempt to find shallow waters with greater oxygen pressure. Another explanation is that gas vesicle proteins have a different role in a more generalized stress response, as has been previously suggested (Lee et al., 2005; Hesketh et al., 2011; Botas et al., 2018), in a process thus far unknown.

Even though this study has been carried out only with *S. coelicolor*, the prevalence of orthologs of the Sco5282/Sco5283 two-component system among different members of the *Streptomycineae* raises the possibility that genetic manipulation to activate this system could be used to modify morphology of *Streptomyces* species that grow in a pelleted form. It will also be interesting to explore whether the altered morphology can be used as a tool to increase extracellular enzyme production.

DATA AVAILABILITY

The datasets generated for this study are available in the NCBI Sequence Read Archive accession number PRJNA499125.

AUTHOR CONTRIBUTIONS

EA-P, DG, GS-C, and LS-G designed the experiments. EA-P, GG-C, DG, and LS-G performed the experiments. EA-P carried out the statistical analysis. EA-P and LS-G wrote the first draft of the manuscript. All authors contributed to the manuscript revision, and read and approved the submitted version.

FUNDING

This work was supported in part by the grant 220020 from the CB2013 fund of the Consejo Nacional de Ciencia y Tecnología (México), and received additional funding from the Programa Institucional La Producción de Biomoléculas de Interés Biomédico en Bacterias y Hongos, of the Instituto de Investigaciones Biomédicas.

ACKNOWLEDGMENTS

We are grateful to the Consejo Nacional de Ciencia y Tecnología (Mexico) for the funding provided. EA-P received a scholarship from the Consejo Nacional de Ciencia y Tecnología as a postgraduate student in the Programa de Maestría y Doctorado en Ciencias Bioquímicas of the Universidad Nacional Autónoma de México.

Abstract—Neurogenesis in the substantia nigra (SN) has been a controversial issue. Here we report that neurogenesis can be induced in the adult rodent SN by transplantation of embryoid body cells (EBCs) derived from mouse embryonic stem cells. The detection of Sox2$^+$ dividing (BrdU$^+$) putative host neural precursor cells (NPCs) between 1 and 6 days post-transplantation (dpt) supported the neurogenic capacity of the adult SN. In agreement with the awakening of NPCs by EBCs, only host cells from implant-bearing SN were able to generate neurosphere-like aggregates in the presence of Egf and Fgf2. Later, at 15 dpt, a significant number of SN Dcx$^+$ neuroblasts were detected. However, a continuous BrdU administration after transplantation showed that only a fraction (about 20–30%) of those host Dcx$^+$ progeny derived from dividing cells and few BrdU$^+$ cells, some of them NeuN$^+$, survived up to 30 dpt. Unexpectedly, 25–30% of Dcx$^+$ or Psa-Ncam$^+$ cells at 15 dpt displayed astrocytic markers such as Gfap and S100b. Using a genetic lineage tracing strategy, we demonstrated that a large proportion of host Dcx$^+$ and/or Tubb3$^+$ neuroblasts originated from Gfap$^+$ cells. Remarkably, new blood vessels formed in association with the neurogenic process that, when precluded, caused a reduction in neuroblast production. Accordingly, two proteins secreted by EBCs, Fgf2 and Vegf, were able to promote the emergence of Dcx$^+$/Psa-Ncam$^+$, Tubb3$^+$ and NeuN$^+$/BrdU$^+$ cells *in vivo* in the absence of EBCs. We propose that the adult SN is a mostly silent neurogenic niche with the ability to generate new neurons by typical and atypical mechanisms. **© 2019 IBRO. Published by Elsevier Ltd. Key words: neurogenesis, astrocytes, substantia nigra, transdifferentiation, transplantation.

INTRODUCTION

In the mammalian adult brain only two neurogenic regions show abundant production of new neurons (Alvarez-Buylla and Lois, 1995;Alvarez-Buylla and Garcia-Verdugo, 2002). The neurogenic niches that harbor dividing neural stem cells (NSC) are the subventricular zone (SVZ) lining the lateral ventricles (Lois and Alvarez-Buylla, 1993) and the subgranular zone (SGZ) in the hippocampus (Cameron et al., 1993). Adult neurogenesis in other brain areas, especially in those affected by neurodegenerative diseases, has been the focus of recent studies (Gould, 2007). In particular, evidence that supports neurogenesis in the substantia nigra (SN) remains controversial. While there is evidence that the SN contains proliferating precursor cells with a demonstrated plasticity to generate new neurons when transplanted to a neurogenic niche (Lie DC et al., 2002), others postulate that dopaminergic neurogenesis continue throughout life, though at a low rate (Albright et al., 2016;Morrison, 2016) and could be increased by a lesion (Zhao et al., 2003;Shan et al., 2006). Conversely, Frielingsdorf et al. (2004) reported the absence of dopaminergic neurogenesis. Alternatively, evidence has been provided to support that new neurons in the SN upon damage may originate from NPCs (neural precursor cells) residing in the aqueduct periventricular region (Hermann et al., 2006;L'Episcopo et al., 2014).

Commonly, neurogenesis in the adult brain is estimated by detecting dividing cells and the presence of neural markers. The caveat of approaches based in these determinations is the assumption that neuronal differentiation in all regions and conditions occurs by a similar mechanism. It is worth considering that the inability to detect neurogenesis in certain

regions may be related to the poor environment for NPC differentiation or for survival of mature neurons under regular physiological conditions. A pro-neurogenic environment may be constantly present or emerge upon particular physiological conditions or damage. We recently showed that the capacity of the adult brain to support neurogenesis could be determined by transplanting cells with neurogenic potential. Embryoid body cells (EBCs) derived from mouse embryonic stem cells (ESCs), which possess a high neurogenic potential (Baizabal and Covarrubias, 2009), efficiently differentiate into neurons in distinct adult brain host regions and conditions. The striatum shows poor capacity to support neurogenesis, but this capacity improves after an experimental damage. Interestingly, the intact SN promotes neurogenesis of transplanted cells with high efficiency, similar to that determined within a classical neurogenic area. Therefore, new neurons in the SN could originate from either migrating NPCs or latent NSCs awaiting for activation signals.

In the present study, we tested the hypothesis that cells with neurogenic potential exist in the adult SN. This consideration arose from the observation of putative Dcx^+/$Psa\text{-}Ncam^+$ neuroblasts surrounding implanted EBCs, particularly abundant in the SN. We provide evidence of the emergence of cells with NPC characteristics in the SN few days after transplantation. Interestingly, many of those Dcx^+/$Psa\text{-}Ncam^+$ neuroblasts appeared to derive from non-dividing glial cells, which are coincident with recent reports supporting that astrocytes are the source of new neurons (Magnusson et al., 2014;Nato et al., 2015). We conclude that new neurons in the SN could originate from residing cells through typical and atypical mechanisms in the presence of proper inducing signals, some of which could be angiogenic factors.

EXPERIMENTAL PROCEDURES

Embryoid body formation

Two mouse ESC lines were used to generate embryoid body aggregates (EBs): the R1 and its derivative R1B5 that constitutively expresses the enhanced green fluorescent protein (Egfp). To generate EBs, we followed the protocol described by Maya-Espinosa et al. (2015). Briefly, ESCs were seeded on gelatin-coated culture plates covered with mitomycin-treated mouse embryonic fibroblasts (MEFs) as feeder cells and grown in M15 medium (DMEM medium supplemented with 15% FBS, 1 mM sodium pyruvate 1X glutamax, 0.1 mM non-essential amino acids, 0.1 mM 2-mercaptoethanol from Gibco). After two days *in vitro*, ESCs were seeded on plates without feeder cells but supplemented with 1000 U of leukemia inhibitory factor (Lif; Chemicon) for 3 days. To form EBs, 5×10^5 ESCs were transferred to non-adherent 10 cm bacterial culture dishes and cultivated during 4 days without Lif; during this time evident aggregates were formed most of them surrounded by endodermal-like cells (Maya-Espinosa et al., 2015). For transplantation, 4-day EBs (Fig. 1A) were disaggregated with 0.25% trypsin, centrifuged and resuspended in Optimem medium (Gibco).

Animals

We used 2–3 months old Wistar male rats (300 g) or 2–3 months old wild-type mice (28–30 g). Depending on the transplantation protocol, in some cases host mice were those of the 129/Sv strain carrying the *Egfp*, the *tdTomato/Egfp* [B6.129(Cg)-*Gt(ROSA)26Sor* $^{tm4(ACTB\text{-}tdTomato\text{-}EGFP)Luo}$/J, https://www.jax.org/strain/007676; referred ahead as tdTomato mice], or two transgenes *Gfap-cre/ERT2* [B6.Cg-Tg (*GFAP-cre/ERT2*)505Fmv/J, https://www.jax.org/strain/012849] and *–tdTomato/Egfp*. In tdTomato mice, all cells constitutively express *tdTomato*, whereas in *Gfap-cre/ERT2*;*Gt(ROSA)26Sor* $^{tm4(ACTB\text{-}tdTomato,\text{-}EGFP)}$ double transgenic mice, after CreERT2-induced recombination in the presence of tamoxifen, only *Gfap* expressing cells turn off *tdTomato* and turn on *Egfp* expression. One week before surgery, double transgenic mice were administered with i.p. tamoxifen (200 mg/kg), five doses in total, one every other day. All animals were maintained under standard colony conditions (12-h light/12-h dark cycle) with food and water *ad libitum*. Animals were sacrificed by a pentobarbital overdose and underwent transcardiac perfusion with a 0.1 M PBS solution followed by a 4% PFA solution. The experiments were carried out in accordance with the local bioethical committee (project number 293) of the Instituto de Biotecnología (Universidad Nacional Autónoma de México).

Transplantation of EBCs and infusion of Fgf2 and Vegf

Stereotaxic coordinates for SN were obtained from Paxinos and Watson (2005) for adult rats (AP −5.0, L −2, DV −8.0) and from Franklin and Paxinos (2013) for adult mice (AP −3.0, L −1.2, DV −4.2). Animals were transplanted under ketamine (10 mg/kg)–xylazine (1 mg/kg) anesthesia by injection of 1 µl of the cell suspension (approximately 1.5×10^5 cells in rats and 5×10^4 cells in mice) using a 5-µl Hamilton syringe. As controls, we considered the intact contralateral SN and animals injected with the delivery medium Optimem. For cell proliferation analysis, rats were injected with one 50 mg/kg i.p. dose of BrdU per day during the first 6 days post-trasplantation (dpt), whereas mice were injected with one 50 mg/kg i.p. dose of BrdU every day from day 3 to day 15. For Fgf2 (fibroblast growth factor) and Vegf (vascular endothelial growth factor) infusions in the SN, 10 ng of recombinant human Fgf2 (Peprotech) and 10 ng of recombinant human Vegf (Peprotech) were embedded in Puramatrix hydrogel (BD) (1:1) and injected in the same coordinates used for EBCs under ketamine–xylazine anesthesia. Angiogenesis inhibition was attained by administering 20 mg/kg i.p. of cyclosporine A (CypA; Sandimmune, Novartis) diluted in saline solution (0.9% *w/v* NaCl), one every other day during 15 days, to tdTomato mice previously transplanted with R1B5 EBCs, as described above.

Neurosphere culture

Neurosphere formation assays were performed on 6-day transplanted and intact contralateral SN in the presence of Egf (epidermal growth factor) and Fgf2 (20 ng/ml each;

INFORME DE LABORES 2019

Peprotech). We followed a protocol similar to the one described by Baizabal et al. (2012). Briefly, we dissected the SN, and the SVZ as a positive control, under a stereoscopic microscope. The dissected tissue was placed in a 6-cm culture dish containing DMEM/F12 and cut into ≈1-mm pieces. Then, the tissue was transferred to a dissociation solution [124 mM NaCl, 5 mM KCl, 3.2 mM $MgCl_2$, 0.1 mM $CaCl_2$, 26 mM $NaHCO_3$, 10 mM D-glucose, 0.2 mg/ml kynurenic acid, 0.67 mg/ml type IV hyaluronidase (SIGMA) and 1.33 mg/ml trypsin (ThermoFisher Scientific)] and incubated for 1 h at 37 °C. This step was followed by the addition of a trypsin inhibitor solution (1 mg/ml; SIGMA) and mechanical dissociation. The cell suspension derived from each tissue fragments was centrifuged at 1500 rpm for 7 min and the pellet was resuspended in 1 ml neurosphere culture media [DMEM/F12 supplemented with 25 μg/ml insulin (Gibco), glutamax 1× (ThermoFisher Scientific), 100 μg/ml transferrin, 20 nM progesterone, 60 μM putrescine, 30 nM selenium, and 2 μg/ml heparin (SIGMA)] containing Fgf2 and Egf (20 ng/ml each). To remove undissociated tissue fragments and debris, the suspension obtained was filtered through a 70-μm nylon membrane (BD Falcon). 1.8×10^5 cells were seeded in 35-mm culture dishes. Cultures were maintained at 37 °C in humidified 5% CO_2–95% atmospheric air incubators for 18 days.

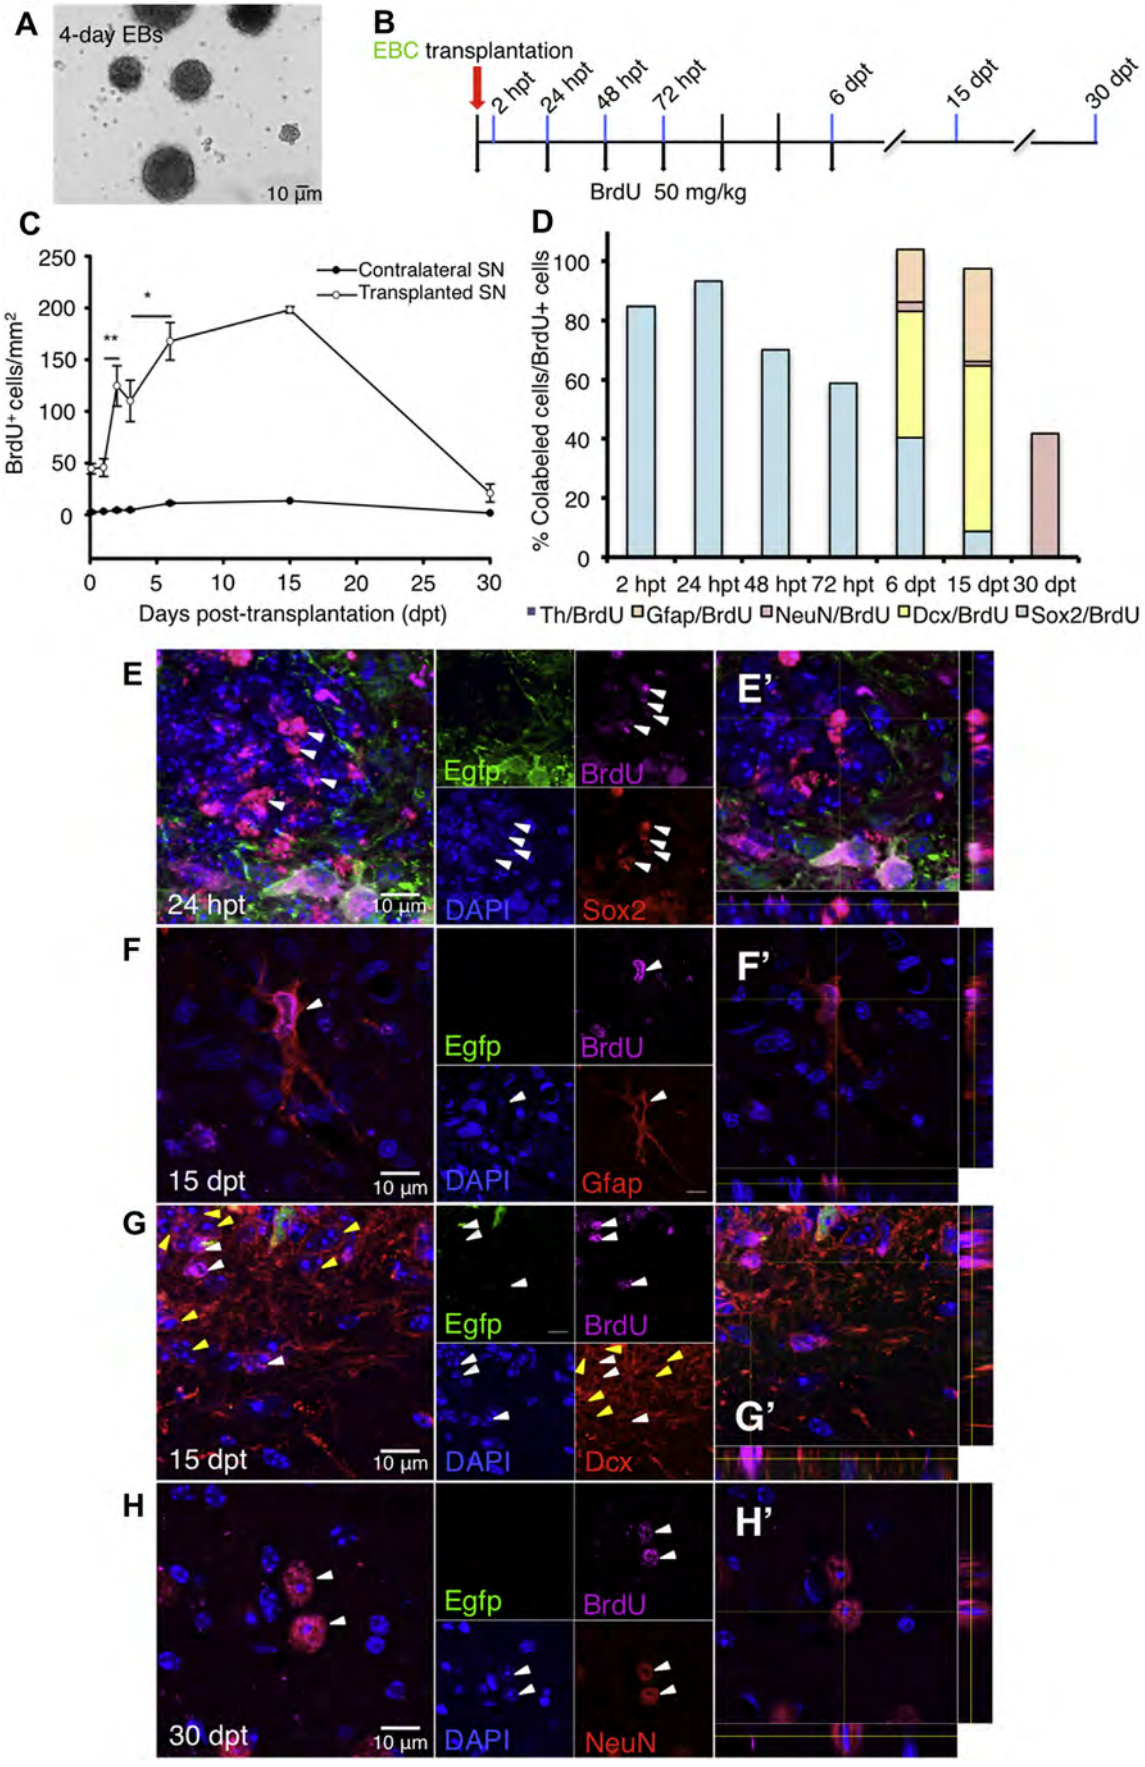
A similar procedure was followed to evaluate the generation of neurospheres from SN cells that were exposed *in vitro* to Vegf and Fgf2 delivered from a Puramatrix hydrogel (BD). Briefly, 20 ng of Vegf and Fgf2 were embedded in a proportion 1:1 with hydrogel. Then, the mixture was left to settle down for 30 min and hydrogel polymerization was induced by adding 50 μl of neurosphere culture media. Finally, 5×10^4 cells were seeded per well (24-well microplate) and cultured for 12 days at 37 °C in a humidified 5% CO_2–95% atmospheric air incubator to allow the formation of neurospheres. At the end of the culture, the number of neurospheres was determined.

Tissue preparation and immunolabeling

All brains were removed and cryopreserved in a 30% sucrose solution. Brain 30-μm coronal sections were obtained using a cryostat and stored as free-floating in an antifreeze solution (25% ethylene glycol, 25% glycerol and 50% 0.1 M PBS) until immunolabeling. We followed a standard technique for immunochemistry, except for BrdU detection in which we added a 1-N HCl incubation step at 37 °C for 30 min after permeabilization. Three slices per brain were selected for analysis of each immunophenotypical marker. Brain slices were rinsed three times with 0.1 M TBS, followed by a 0.1% Triton X-100 incubation and treated with 1× immune DNA-retriever citrate buffer (Bio SB) at 65 °C for 30 min, and washed three times with TBS. After blocking in a 10% donkey serum/0.1% TX-100 solution, the slices were incubated in the corresponding primary antibody (Table 1) solution (containing 1% donkey serum/ 0.1% TX-100) overnight at 4 °C. After three times rinsing in TBS, slices were incubated for 2 h at room temperature with the appropriate secondary antibody (Table 1) 1:1500 in a solution containing 2% donkey serum/ 2% TX-100. Finally, the brain slices were counterstained with a 1:10,000 DAPI solution, rinsed with TBS and mounted in glass slides with Prolong Gold (ThermoFisher Scientific) mounting medium. We used typical neurogenic zones and regions (SVZ-OB and SGZ-dentate gyrus) as internal controls for the proliferation marker BrdU, and NSC and neuroblast markers.

Imaging and cell counting

Since no difference in response to EBC transplantation was evident for cells in the SN pars compacta or the SN pars reticulata portions, the whole SN was considered for the analysis. Endogenous reporter gene expression such as *Egfp* from the R1B5 cell line or the *tdTomato/Egfp* from the transgenic mice allowed us to discriminate between the host and the transplanted cells. We use an Olympus FV1000 confocal microscope for image acquisition. Cell and blood vessel counting was carried out in coronal sections considering the area comprised within the adjacent 600 μm to the transplanted cells or the hydrogel and covering their rostrocaudal distribution. We obtained three brain slices from at least three independent subjects, and two photomicrographs were taken from each slice with a 20× objective; Z stack images were taken with a 60× objective to analyze co-expression when required. All results are expressed as the mean ± SEM (cells/mm^2, blood vessels/mm^2 or transplant diameter) or as the percentage (mean ± SEM) of double positive cells from the total Gfap or Egfp positive cells when applicable.



Statistical analysis

Cell count data were analyzed with the Shapiro–Wilk normality test and Levene equal variance test to confirm their normal distribution. To compare two groups the t-student test was done and to compare three or more groups we performed a one way-ANOVA test. SIGMAPLOT V12.0 software (Systat Software, Inc.) was used for all statistical analysis of data. For comparisons between the number of $BrdU^+$ cells at two subsequent time points (i.e. 2 hpt vs 24 hpt; 24 hpt vs 48 hpt), the multiple comparison procedure (Fisher LSD Method) was applied. P values of statistically significant differences are indicated as: *$p < 0.05$ or **$p < 0.01$.

RESULTS

Transplantation of EBCs stimulates neurogenesis in the adult rat and mouse SN

Proliferation of putative NPCs has been associated with active neurogenesis. Accordingly, BrdU incorporation occurred above basal levels immediately (2 h) after transplantation of EBCs to the adult rat SN increasing, with an apparent synchrony (considering a 20-h cell cycle), up to 48 h post-transplantation (hpt; Fig. 1B, C and Table 2). After this period, incorporation rate diminished by 72 hpt, but a significant number of $BrdU^+$ cells continued to be detected the following days and few remained at 30 dpt (Fig. 1C and Table 2). Very few cells incorporated BrdU in the contralateral

SN (Fig. 1C and Table 2). The NPC identity of most $BrdU^+$ cells detected shortly after transplantation (i.e., up to 72 hpt) is supported by the detection of Sox2 in the majority of them (Fig. 1D, E, E' and Table 3).

Sox2 expression, as well as other similar markers, is not exclusive of NPCs. In particular, reactive astrocytes proliferate upon brain damage and express several NPC markers (Gotz et al., 2015). Actually, many glial cells with reactive astrocyte characteristics (i.e., high levels of Gfap, hypertrophy and proliferation) were found after EBCs transplantation (Fig. 1D, F, F' and Table 3). However, since reactive astrocytes have no neurogenic potential *in vivo*, the NPC identity of the proliferating $Sox2^+$ cells emerging in response to EBCs transplantation can be determined by tracing the neuronal progeny from them (i.e., those retaining the incorporated BrdU). In agreement with this possibility, as incorporation of BrdU diminished, an increasing number of $BrdU^+$ cells were also positive for the immature neuronal marker Dcx (white arrowheads in Fig. 1G; see also Fig. 1D and Table 3) but, in addition, many endogenous Dcx^+ cells detected were not positive for BrdU (yellow arrowheads in Fig. 1G; see also Table 3). In coincidence with the disappearance of transplanted cells, very few cells derived from the proliferating NPCs remained in the long term (30 dpt; Fig. 1C). Occasionally, $BrdU^+$ cells containing the mature neuronal marker NeuN were found at this time (Fig. 1D, H, H' and Table 3). Similar to the fate of NPCs derived from the transplanted cells (Maya-Espinosa et al., 2015), no cell positive for Th, an early marker of dopaminergic neurons, derived from dividing NPCs.

Similar results were obtained when transplantations were performed in the mouse (Fig. 2A). Several $BrdU^+$ cells were detected at 6 dpt, their number increased by 15 dpt, but very few were found at 30 dpt (Fig. 2B and Table 4). NPCs were detected by the presence of Sox1 and Nes (also named Nestin), markers more restricted to activated NPCs than Sox2 (Venere et al., 2012;Codega et al., 2014). At 6 dpt, a significant proportion of $BrdU^+$ cells expressed *Nes* and *Sox1* (Fig. 2C–E and Table 5). Supporting the NPC identity of these proliferating cells, nearly half of the $BrdU^+$ cells detected at 15 dpt expressed *Dcx* (Fig. 2C, F, F' and Table 5) but, in addition, many endogenous Dcx^+ cells detected were not positive for BrdU (yellow arrowheads in Fig. 2F). Since administration of BrdU was maintained from

Fig. 1. Transplantation of EBCs induces neurogenesis in the adult rat SN. (A) ESCs form spherical aggregates (EBs) under non-adherent conditions. For transplantation, 4-day EBs were disaggregated. (B) Schematic representation of the experimental strategy in the rat; EBCs from R1B5 cells ($Egfp^+$) were used for these experiments. (C) BrdU-labeled cells in the adult rat transplanted SN (white circles) and contralateral SN (dark circles). Error bars indicate SEM; P values are indicated as $*p < 0.05$ and $**p < 0.01$. (D) Percentage of $BrdU^+$ cells colabeled with: Sox2, Gfap, Dcx, NeuN and Th in the rat SN at different time points after transplantation. (E–H) Confocal Z-projections showing $BrdU^+$ cells colabeled with the neural markers Sox2 (at 24 hpt), Gfap (at 15 dpt), Dcx (at 15 dpt) and NeuN (at 30 dpt) in the rat SN. White arrowheads indicate cells colabeling with BrdU and yellow arrowheads in (G) indicate those only labeled with Dcx. (E'–H') Orthogonal views. Scale bar 10 μm. INFORME DE LABORES 2019

Table 2. BrdU-labeled cells per mm^2 (mean ± SEM) in the transplanted adult rat SN.

Post-transplantation period	Rat	
	Contralateral SN	Transplanted SN
2 hpt (n = 2)	1.23, 3.70	39.56, 49.45
24 hpt (n = 3)	3.29 ± 0.41	45.74 ± 8.56
48 hpt (n = 4)	4.32 ± 1.28	124.56 ± 19.58
72 hpt (n = 4)	4.63 ± 1.05	110.04 ± 20.05
6 dpt (n = 5)	11.20 ± 1.21	167.68 ± 18.12
15 dpt (n = 3)	13.51 ± 2.55	198.20 ± 3.17
30 dpt (n = 2)	1.63, 1.63	12.36, 29.67

BrdU-labeled cells were counted (see Material and Methods) at different times post-transplantation. The corresponding contralateral SN was used as control for each time. The number of subjects (n) per group is specified between parentheses.

the 3 to 15 dpt, and up to just 2 h before sacrifice, neuroblasts without detectable BrdU unlikely emerged due to incorporated BrdU dilution after extensive proliferation. At 30 dpt, some $BrdU^+$ expressed *NeuN* (Fig. 2C, G ,G' and Table 5) but, again no $BrdU^+$ cell was found positive for Th (Fig. 2C). Furthermore, no cell positive for Lmx1a or Neurog2, two early markers of mesencephalic dopaminergic progenitors detected in embryos before *Th* expression (Guerrero-Flores et al., 2017), was found. It is relevant to mention that in mice, in contrast with observations in rats [present report and in Maya-Espinosa et al., 2015], transplanted EBCs continued proliferating and a large mass of transplanted cells was commonly observed at 30 dpt, a condition that might affect the final outcome.

Transplanted EBCs efficiently differentiate into Dcx^+ neuroblasts in the SN (Maya-Espinosa et al., 2015). To discard the possibility that the Dcx^+ cells detected in previous experiments were not the result of EBCs progeny that downregulated *Egfp* expression, we transplanted wild-type EBCs to an $Egfp^+$ host brain (Fig. 3A, A') or the $Egfp^+$ R1B5 EBCs to the brain of tdTomato mice (Fig. 3B, B'). As expected for the host origin of Dcx^+ cells surrounding the implant, a high proportion of them were $Egfp^+$ cells (315.6 ± 26.7 cells/mm^2) or $tdTomato^+$ (358.24 ± 42.18 cells/mm^2), respectively. Nonetheless, EBCs carried the inducing neurogenic factor, since very few cells incorporated BrdU and no Dcx^+ cell was found in the contralateral intact SN or after injecting the basal culture medium (Optimem) without EBCs (Figs. 1C, 2B and Tables 2 and 4). In agreement with this conclusion, mouse embryonic fibroblasts (MEFs) transplantation to the SN of $Egfp^+$ mice produced a moderate glial reaction but no Dcx^+ cell was found at 15 dpt (Fig. 3C).

Table 3. BrdU-labeled cells per mm^2 (mean ± SEM) colabeling with neural, neuronal and glial cell markers in the transplanted adult rat SN.

Post-transplantation period	Cell markers	Number of cells (% $BrdU^+$ cells)
2 hpt	$Sox2^+/BrdU^+$	35.85 (84.72%)
(n = 2)	$Sox2^+/BrdU^-$	80.98
24 hpt	$Sox2^+/BrdU^+$	41.62 ± 6.3 (93.15 ± 3.43%)

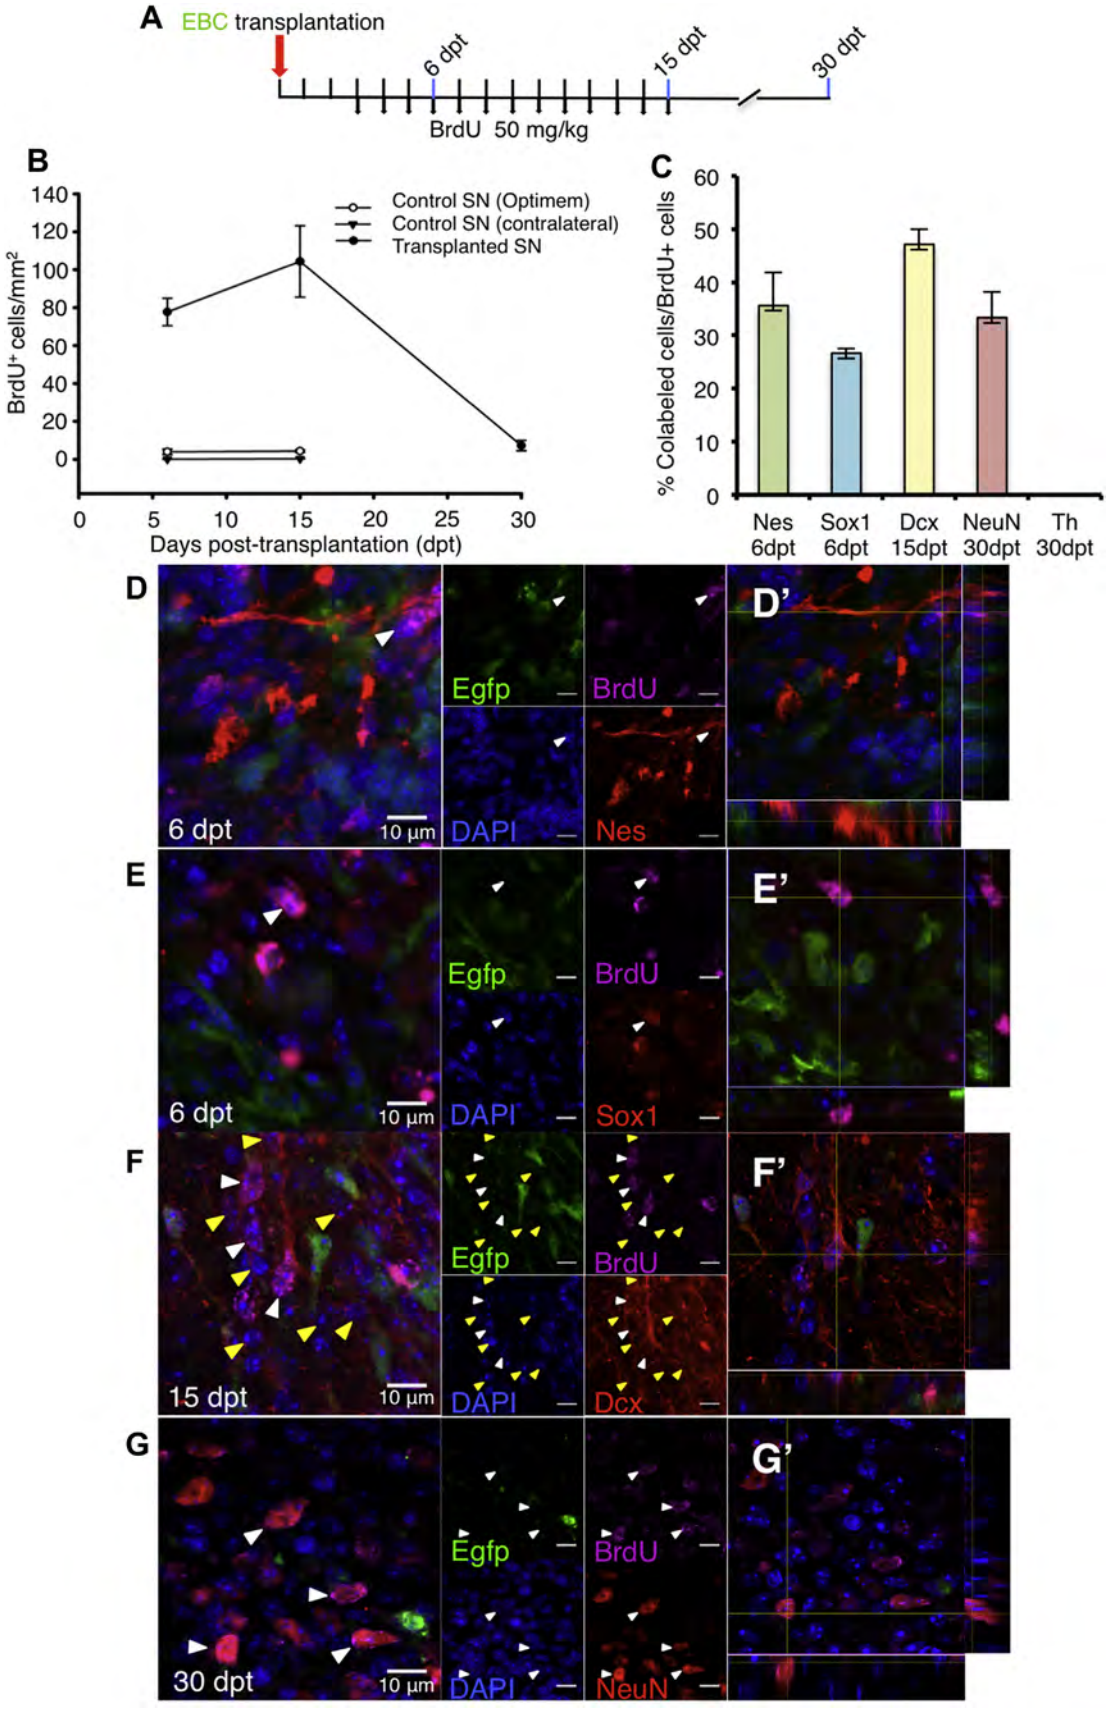
6 dpt	$Sox2^+/BrdU^+$	68.85 ± 14.18 (46.08 ± 5.99%)
(n = 5)	$Sox2^+/BrdU^-$	233.2 ± 46.27
15 dpt	$Sox2^+/BrdU^+$	12.71 ± 4.75 (8.87 ± 4.87%)
(n = 3)	$Sox2^+/BrdU^-$	7.24 ± 4.64
6 dpt	$Nes^+/BrdU^+$	30.91 ± 6.18 (28.84 ± 9.61%)
(n = 3)	$Nes^+/BrdU^-$	90.25 ± 8.65
6 dpt	$Dcx^+/BrdU^+$	68.92 ± 6.02 (48.73 ± 6.65%)
(n = 4)	$Dcx^+/BrdU^-$	106.33 ± 11.95
15 dpt	$Dcx^+/BrdU^+$	91.84 ± 23.95 (55.83 ± 4.64%)
(n = 3)	$Dcx^+/BrdU^-$	175.21 ± 44.06
6 dpt	$Gfap^+/BrdU^+$	39.56 ± 2.47 (17.46 ± 0.60%)
(n = 3)	$Gfap^+/BrdU^-$	77.48 ± 23.56
15 dpt	$Gfap^+/BrdU^+$	51.1 ± 4.36 (30.11 ± 3.66%)
(n = 3)	$Gfap^+/BrdU^-$	97.26 ± 27.98
6 dpt (n = 4)		4.94 ± 0.8 (3.05 ± 1.27%)
15 dpt (n = 3)	$NeuN^+/BrdU^+$	2.47 ± 0 (1.42 ± 0.85%)
30 dpt (n = 2)		8.65 (41.87%)
30 dpt (n = 2)	$Th^+/BrdU^+$	0%

BrdU-labeled cells that also showed the markers indicated were counted (see Material and Methods) at different times post-transplantation; cells positive for the marker but negative for BrdU were also counted. The number of subjects (n) per group and the percentage (mean ± SEM) of total $BrdU^+$ cells are specified between parentheses.

INFORME DE LABORES 2019

Cells of the transplanted adult mouse SN generate neurospheres

To confirm the emergence of cells with NPC characteristics after transplantation of EBCs, we performed a neurosphere formation assay for cells derived from the intact and transplanted SN at 6 dpt (Fig. 4A). In agreement with the abundant number of cells expressing NPC markers found at this stage in the transplanted SN, neurospheres-like aggregates were formed with cells from the host tissue (51.0 ± 10.8 neurospheres from 1.8 × 10^5 total cells; Fig. 4B, C) but none from cells of the intact SN. The time to form these neurospheres was longer than that required to form neurospheres from SVZ cells (15 vs. 7 days, respectively; Fig. 4B, C). In addition, they were generally smaller in size in comparison with those derived from the SVZ (around 80 vs. 250 μm diameter) and evidently different from those flat colonies formed by the EB-derived cells (Egfp$^+$; Fig. 4B, bottom panel). Nonetheless, to confirm their NPC properties and similarity to SVZ cells they were able to produce secondary neurospheres (Fig. 4D) and expressed typical neurosphere markers such as *Nes* and *Gfap* (Fig. 4E; right panel).



Non-dividing resident Gfap$^+$/S100b$^+$ cells acquire neuroblast markers after EBCs transplantation

The number of total Dcx$^+$ cells detected in the rat SN after EBCs transplantation moderately increased (1.5-fold) from 6 dpt to 15 dpt (Table 3). However, although BrdU was applied during the first 6 days after transplantation, only a fraction of those Dcx$^+$ cells colabeled with BrdU (approximately 30% at 15 dpt). Thus, activation of NPCs and generation of Dcx$^+$ cells might occur after 6 dpt. However, for transplantation to mouse SN, BrdU was applied daily from 3 to 15 dpt and, yet, the proportion of Dcx$^+$/BrdU$^+$ was not larger than 20% of total Dcx$^+$ cells (Table 5). This would mean that the remaining 80% Dcx$^+$ cells originated from non-dividing progenitor cells. Accordingly, many Sox2$^+$ cells emerging at 6 dpt did not show BrdU incorporation (Tables 3 and 5). These observations opened the possibility to the participation of a differentiated cell type (e.g., astrocytes) as a precursor of neuroblasts by a mechanism that does not involve cell divisions. In the adult brain, Gfap$^+$ cells represent either parenchymal astrocytes or NSCs in the neurogenic areas. In the intact SN, Gfap$^+$ cells are scattered mainly within the SNpr and the glia limitans layer (Fig. 3D, left panel). Interestingly, we found many Gfap$^+$ cells around the implanted cells (Fig. 3D, right panel), with a corresponding reduction in the glia limitans layer, some of which were also labeled for Dcx at 6 dpt (4.15 ± 0.97% of total Gfap$^+$ cells within 600 μm from the transplant border, n = 3; Fig. 5H), which number markedly increased by 15 dpt (25.46 ± 2.37%, n = 7; Fig. 5B, B', F, F′, I). Similar results were obtained in Dcx colabeling determinations with S100b at 15 dpt (29.42 ± 4.4% S100b$^+$/Dcx$^+$, n = 7, Fig. 5G, G', I; see also S100b/Psa-Ncam colabeling, n = 3, in Fig. 5E, I), a marker that characterizes a terminal maturation stage of astrocytes (Raponi et al., 2007) and is not expressed by SVZ NSC (Codega et al., 2014).

The fact that the number of Dcx$^+$ cells increased while the proportion of Dcx$^+$ cells also positive for Gfap remained constant (17.51 ± 3.38% at 6 dpt and 18.15 ± 2.29% at 15 dpt) suggests that the co-expression of astrocytic and neuroblast markers is a transient event. As expected, Psa-Ncam$^+$/Sox2$^+$ cells were rarely detected (0.75 ± 0.29% of total Psa-Ncam$^+$ cells, n = 4; Fig. 5A, I), but a significant proportion of cells Sox2$^+$/Gfap$^+$, (39.85 ± 4.02% at 6 dpt, and 32.16 ± 1.09% at 15 dpt, n = 3; Fig. 5C, C', H, I) or Nes$^+$/Gfap$^+$ (38.83 ± 4.36% at 6 dpt and 57.02 ± 3.05% at 15 dpt, n = 3; Fig. 5D, D', H, I) were found. Many of those cells might be reactive astrocytes, but the possibility that some of them represent a transient event to become a neuroblast should be considered. In concordance with data of a recent report by Magnusson et al. (2014), these observations suggest that fully differentiated parenchymal astrocytes can give rise to new neurons, in our case, possibly through a direct transdifferentiation process that does not require cell divisions. It is important to mention that at 15 dpt Dcx$^+$/Tubb3$^+$ cells or Dcx$^+$/Th$^+$ positive cells were not detected discarding a neuronal dedifferentiation process. Tubb3 is a neuronal marker present in young and mature neurons that emerges as Dcx disappears.

Resident Gfap$^+$ cells give rise to new neurons in the transplanted SN

To confirm our previous findings, EBCs from wild-type ESC (R1 line) were transplanted to the SN of double transgenic mice Gfap-Cre/ERT2;*Gt(ROSA)26Sor$^{tm4(ACTB-tdTomato,-EGFP)}$*. Before transplantation, these mice were treated with tamoxifen such that the tdTomato sequence was floxed by the Cre/ERT2 and *Egfp* expression occurred in Gfap$^+$ cells (Fig. 6A). Using this protocol, the recombination efficiency obtained was around 30% of all Gfap$^+$ cells detected in the SN; full recombination might not be achieved likely due to a variable *Gfap* expression among astrocytes (Ganat et al., 2006), but it is relevant to mention that >85% of Egfp$^+$ expressed *Gfap* in the contralateral SN. We were not able to detect any Egfp$^+$/NG2$^+$ (oligodendrocyte precursor cell) or Egfp$^+$/O4$^+$ (oligodendrocyte), while some Egfp$^+$/Nes$^+$ and many Egfp$^+$/Dcx$^+$ cells (Fig. 6C, C', E) were detected after transplantation. At 15 dpt, 70.48 ± 2.79% (519.78 ± 89.65 cells/mm^2; n = 3) of the Egfp$^+$ cells were also positive for Gfap (Fig. 6B, E) and 29.35 ± 3.29% (196.32 ± 25.10 cells/mm^2; n = 3) at 30 dpt (Fig. 6E). Interestingly, among the Egfp$^+$ cells, 53.49 ± 8.07% (484.49 ± 76.13 cells/mm^2) and 24.46 ± 4.82% (152.69 ± 33.5 cells/mm^2) at 15 dpt (n = 4), and 23.98 ± 1.90% (132.68 ± 33.03 cells/mm^2) and 27.27 ± 2.97% (189.38 ± 56.18 cells/mm^2) at 30 dpt (n = 4) cells were Dcx$^+$ or Tubb3$^+$, respectively (Fig. 6C–E). Consistent with the above determinations showing that some Gfap$^+$ cells were also expressing neuroblast markers (Fig. 5), the percentage of cells with neuroblast/neuronal markers among the Egfp$^+$ cells was larger than the percentage of cells that were Egfp$^+$/Gfap$^-$. These results confirm that a high percentage of putative neuroblasts emerging around the implanted EBCs in the SN derived from Gfap$^+$ cells and could generate new neurons. In fact, in addition to the detection of Egfp$^+$ cells colabeling with neuronal markers, a neuronal morphology could be revealed in some of them (Fig. 6F).

INFORME DE LABORES 2019

Angiogenic EBC-secreted factors induce neurogenesis in the SN in the absence of EBC transplantation

In comparison with the intact SN (Fig. 7A), an increased immunoreactivity to CD31, a blood vessel marker, was associated with the emerging Dcx$^+$ cells in the EBCs transplanted SN (Fig. 7B). Furthermore, some of these Dcx$^+$ cells showed a tight association with blood vessels (Fig. 7C; white arrowheads in inset Fig. 7C'), suggesting an interaction similar to the one observed in migrating neuroblasts from the SVZ to the olfactory bulb (Bovetti et al., 2007;Whitman et al., 2009). It is relevant to note that blood vessels are evident in the tdTomato mouse without any specific labeling (see Figs. 7 and 8). To determine the role of blood vessels in the EBC-induced neurogenic process, tdTomato mice were treated with CypA, a calcineurin inhibitor that reduces Vegf-mediated angiogenesis (Hernandez et al., 2001;Rafiee et al., 2004), after transplanting R1B5 EBCs to the SN. In comparison to controls (Fig. 7D, D'), mice treated with CypA (Fig. 7E, E') showed a marked reduction in transplant growth (Fig. 7F; 252.48 ± 15.14 μm vs. 432.26 ± 89.0 μm, n = 3) in association with a decreased number of CD31$^+$ blood vessels around it (Fig. 7G; 256.23 ± 11.11 blood vessels/mm^2 vs. 212.51 ± 0.786 blood vessels/mm^2, n = 3). Interestingly, these effects were accompanied by a significant reduction in the number of Dcx$^+$ putative neuroblasts (Fig. 7D, E, H; 101.05 ± 8.59 cells/mm^2 vs. 358.24 ± 42.18 cells/mm^2, n = 3). In agreement with these observations, a reduction in blood vessels (control group, 366.15 ± 18.31 blood vessels/mm^2 vs. CypA group, 323.24 ± 7.72 blood vessels/mm^2; n = 3) and in the number of Dcx$^+$ cells (control group, 43.39 ± 2.06 cells per field vs CypA group, 36.46 ± 6.58 cells per field; n = 3) was also observed in the neurogenic dentate gyrus of CypA-treated mice.

Considering these latter observations and the soluble factors secreted by EBCs in culture (Fathi et al., 2009;Ngangan et al., 2014), we tested Vegf and Fgf2 as molecules contributing to the activation of neurogenesis in the SN, both with angiogenic (Cuevas et al., 1993;Seo et al., 2013) and neurogenic (Kim et al., 2006;Luo et al., 2015;Shen et al., 2016) properties. Interestingly, we observed that Vegf alone or in combination with Fgf2 (embedded in Puramatrix hydrogel) promoted the generation of neurospheres from SN cells, whereas no neurosphere was formed in presence of the hydrogel vehicle alone (data not shown). Therefore, Vegf and Fgf2 were embedded in hydrogel and implanted in the SN of tdTomato mice for their *in vivo* delivery and testing of their neurogenic inducing activity. Fifteen days postinjection (dpi), in contrast with the SN injected with the vehicle (Fig. 8A), though in a smaller quantity than that generated by transplanted EBCs (185.15 ± 5.39 cells/mm2, n = 4 vs. 358.24 ± 42.18 cells/mm^2, n = 4), many Dcx$^+$ cells were detected (Fig. 8B). Furthermore, and similar to the SN with transplanted EBCs, we detected an association between Dcx$^+$ cells and blood vessels (Fig. 8C, C'). At 30 dpi the number of Dcx$^+$ cells decreased (92.17 ± 3.77 cells/mm^2, n = 3; Fig. 8D, D', I) while NeuN$^+$ (82.52 ± 20.29 cells per mm^2, n = 5; Fig. 8E, E', G–I) and Tubb3$^+$ cells (146.51 ± 6.8 cells/mm^2, n = 3; Fig. 8F, I) appeared around the implanted hydrogel (those within a 600-μm distance from the implanted hydrogel) suggesting a progressive neurogenic process, going from Dcx neuroblast, transiting through Tubb3 immature neurons, up to becoming Tubb3/NeuN mature neurons (Zhang and Jiao, 2015).

Table 4. BrdU-labeled cells per mm^2 (mean ± SEM) in the transplanted and control adult mouse SN.

Post-transplantation period	Mouse		
	Vehicle	Contralateral SN	Transplanted SN
6 dpt	3.98 ± 1.43 (n = 3)	0.09 ± 0.03 (n = 5)	77.67 ± 7.2 (n = 10)
15 dpt	4.32 ± 0.61 (n = 3)	0.29 ± 0.02 (n = 4)	104.4 ± 18.85 (n = 4)
30 dpt	ND	ND	7.21 ± 2.71 (n = 7)

BrdU-labeled cells were counted (see Material and Methods) at different times post-transplantation. The corresponding contralateral SN and the SN injected with the vehicle (Optimem medium) were used as controls for 6 and 15 dpt (ND, not determined). The number of subjects (n) per group is specified between parentheses.

However, in mice that were continuously administered with BrdU after injection of factors, only 16% of all NeuN$^+$ cells around the hydrogel colabeled with BrdU (13.18 ± 2.62 NeuN$^+$/BrdU$^+$ cells/mm^2, n = 3; Fig. 8E, E', I), possibly meaning poor survival of new neurons. We traced the possible astrocytic origin of new neurons induced by Vegf and Fgf2 by searching for Egfp$^+$ neurons/neuroblasts around the growth factors-embedded hydrogel in the SN of mice Gfap-Cre/ERT2;*Gt(ROSA)26Sor* $^{tm4(ACTB-tdTomato,-EGFP)}$ previously treated with tamoxifen. Interestingly, some Dcx$^+$/Egfp$^+$ at 15 dpi (Fig. 9A, A') and Tubb3$^+$/Egfp$^+$ cells at 30 dpi (Fig. 9B, B') were detected, as well as some Egfp$^+$ cells with neuronal morphology (Fig. 9C), though the proportion was apparently low. Therefore, the combination of Vegf and Fgf2 is capable of inducing a conversion from poorly dividing Gfap$^+$ cells to new neurons in the SN, as observed after EBCs transplantation, although with much lower efficiency. Accordingly, very few cells co-localizing Gfap and Psa-Ncam (4.56 ± 1.94%, n = 3; Fig. 9D) were found, in comparison with the high frequency of co-localization between the neuroblast markers Psa-Ncam and Dcx (97.59 ± 2.58%, n = 3; Fig. 9E). These latter data suggest that, unlike the effect of EBCs transplantation, Vegf and Fgf2 promoted mostly a neurogenic process through the activation of NSCs.

Fig. 2. Transplantation of EBCs induces neurogenesis in the adult wild-type mouse SN. (A) Schematic representation of the experimental strategy in the mouse; EBCs from R1B5 cells (Egfp$^+$) were used for these experiments. (B) BrdU-labeled cells in the transplanted adult mouse SN (dark circles), contralateral SN (dark triangles) and Optimem-injected SN (white circles). Error bars indicate the SEM. (C) Percentage of BrdU$^+$ cells colabeled with: Nes and Sox1 at 6 dpt, Dcx at 15 dpt, NeuN and Th at 30 dpt; ND, not detected. (D–G) Confocal Z-projections showing BrdU$^+$ cells colabeled with Sox1, Nes, Dcx and NeuN markers in the mouse SN. White arrowheads indicate cells colabeling with BrdU and yellow arrowheads in (F) indicate those only labeled with Dcx. (D'–G') Orthogonal views. Scale bar 10 μm.

INFORME DE LABORES 2019

Table 5. Number of BrdU-labeled cells per mm^2 (mean ± SEM) colabeling with neural and neuronal markers in the transplanted adult mouse SN.

Post-transplantation period	Cell markers	Number of cells (percentage of $BrdU^+$ cells)
6 dpt	$Sox1^+/BrdU^+$	20.71 ± 5.18 (35.61 ± 0.89%)
(n = 3)	$Sox1^+/BrdU^-$	36.47 ± 11.17
6 dpt	$Nes^+/BrdU^+$	21.26 ± 4.39 (26.66 ± 6.31%)
(n = 4)	$Nes^+/BrdU^-$	37.09 ± 6.72
15 dpt	$Dcx^+/BrdU^+$	58.11 ± 8.47 (47.13 ± 2.87%)
(n = 4)	$Dcx^+/BrdU^-$	274.48 ± 25.77
30 dpt	$NeuN^+/BrdU^+$	2.47 ± 0.9 (33.33 ± 4.81%)
(n = 3)	$Th^+/BrdU^+$	0%

BrdU-labeled cells that also showed the markers indicated were counted (see Material and Methods) at different times post-transplantation; cells positive for the marker but negative for BrdU were also counted. The number of subjects (n) per group and the percentage (mean ± SEM) of total $BrdU^+$ cells are specified between parentheses.

DISCUSSION

Adult neurogenesis in the mammalian brain seems to be a restricted process to specific regions. However, based on experimental evidence it has been proposed that, albeit at a low rate, several brain areas possess a neurogenic capacity or nest an NSC population that is prompted to initiate a neurogenic process upon the emergence of activating signals (Lie et al., 2002;Zhao et al., 2003;Gould, 2007;Albright et al., 2016;Morrison, 2016). The present work was focused on evaluating the neurogenic capacity of the adult SN taking advantage of factors produced by EBCs which, in the context of embryonic (Baizabal and Covarrubias, 2009) and adult brain (Maya-Espinosa et al., 2015) environments, carry out a neurogenic process. Our results reveal the presence of quiescent NSCs and the induction of what appears to be an astrocyte to neuron transdifferentiation phenomenon in the adult SN.

Activation of quiescent NSCs

Activation of quiescent NSCs (Codega et al., 2014) in neurogenic niches is a constant process that can be modulated by specific signals (Alvarez-Buylla and Lim, 2004;Conover and Notti, 2008). In particular, injury activates NSCs in both hippocampus and SVZ. Interestingly, blood vessels are commonly associated with neurogenic niches and angiogenesis increases upon NSC activation (Palmer et al., 2000;Licht and Keshet, 2015). These relationships could also be present in other regions in which neurogenesis is not a constant

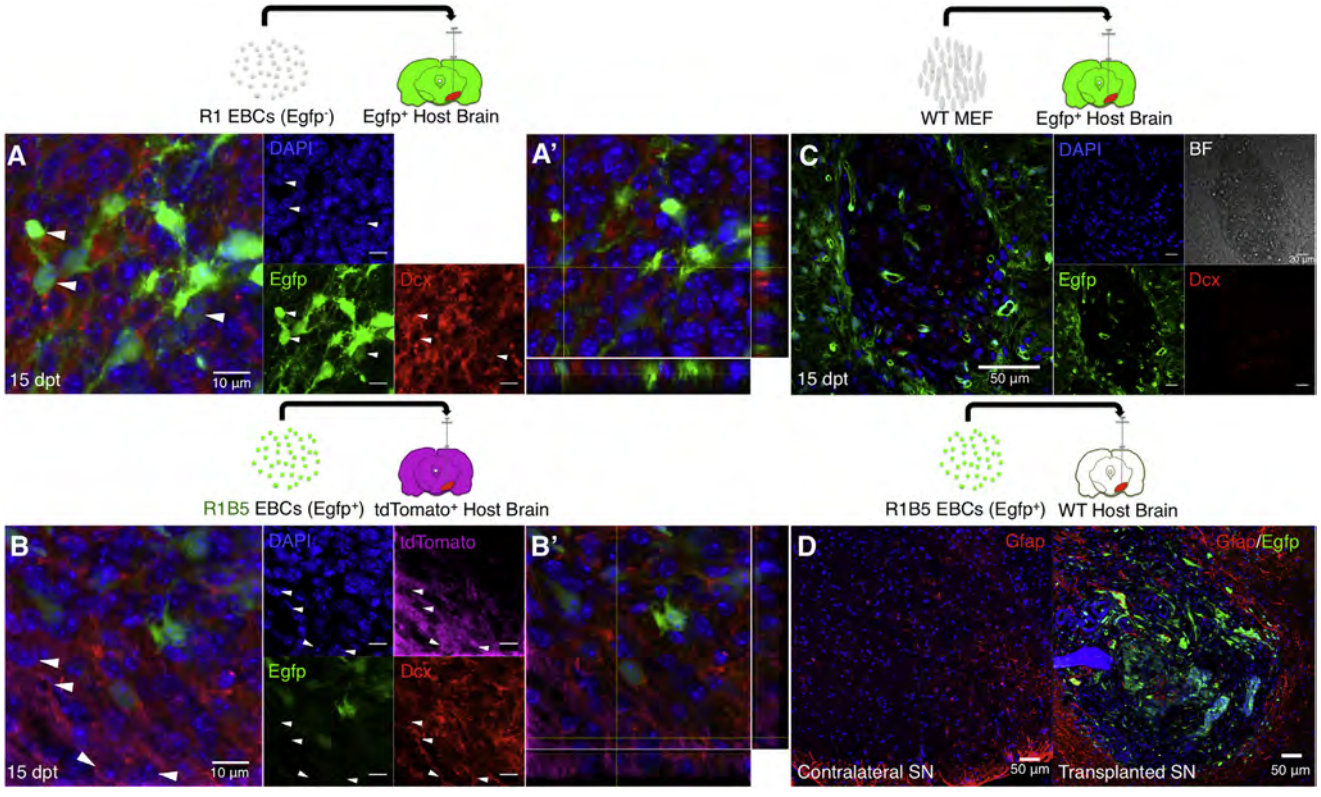

Fig. 3. Putative neuroblasts (Dcx^+ cells) and astrocytes ($Gfap^+$ cells) around the transplanted EBCs in the SN are of host origin. Confocal Z-projections of: (A) Endogenous $Egfp^+/Dcx^+$ cells (white arrowheads) detected 15 days after transplantation of R1 EBCs (no fluorescent marker present) to an $Egfp^+$ host brain (A', orthogonal view); (B) Endogenous $tdTomato^+/Dcx^+$ cells (white arrowheads) detected 15 days after transplantation of R1B5 EBCs ($Egfp^+$) to a $tdTomato^+$ host brain (B′, orthogonal view). (C) No Dcx^+ cell was detected 15 days after transplantation of wild-type MEFs to an $Egfp^+$ host brain. (D) In contrast with the contralateral intact SN, many $Gfap^+$ cells were detected in the transplanted SN parenchyma of wild-type mice 15 days after transplantation of R1B5 EBCs.

INFORME DE LABORES 2019

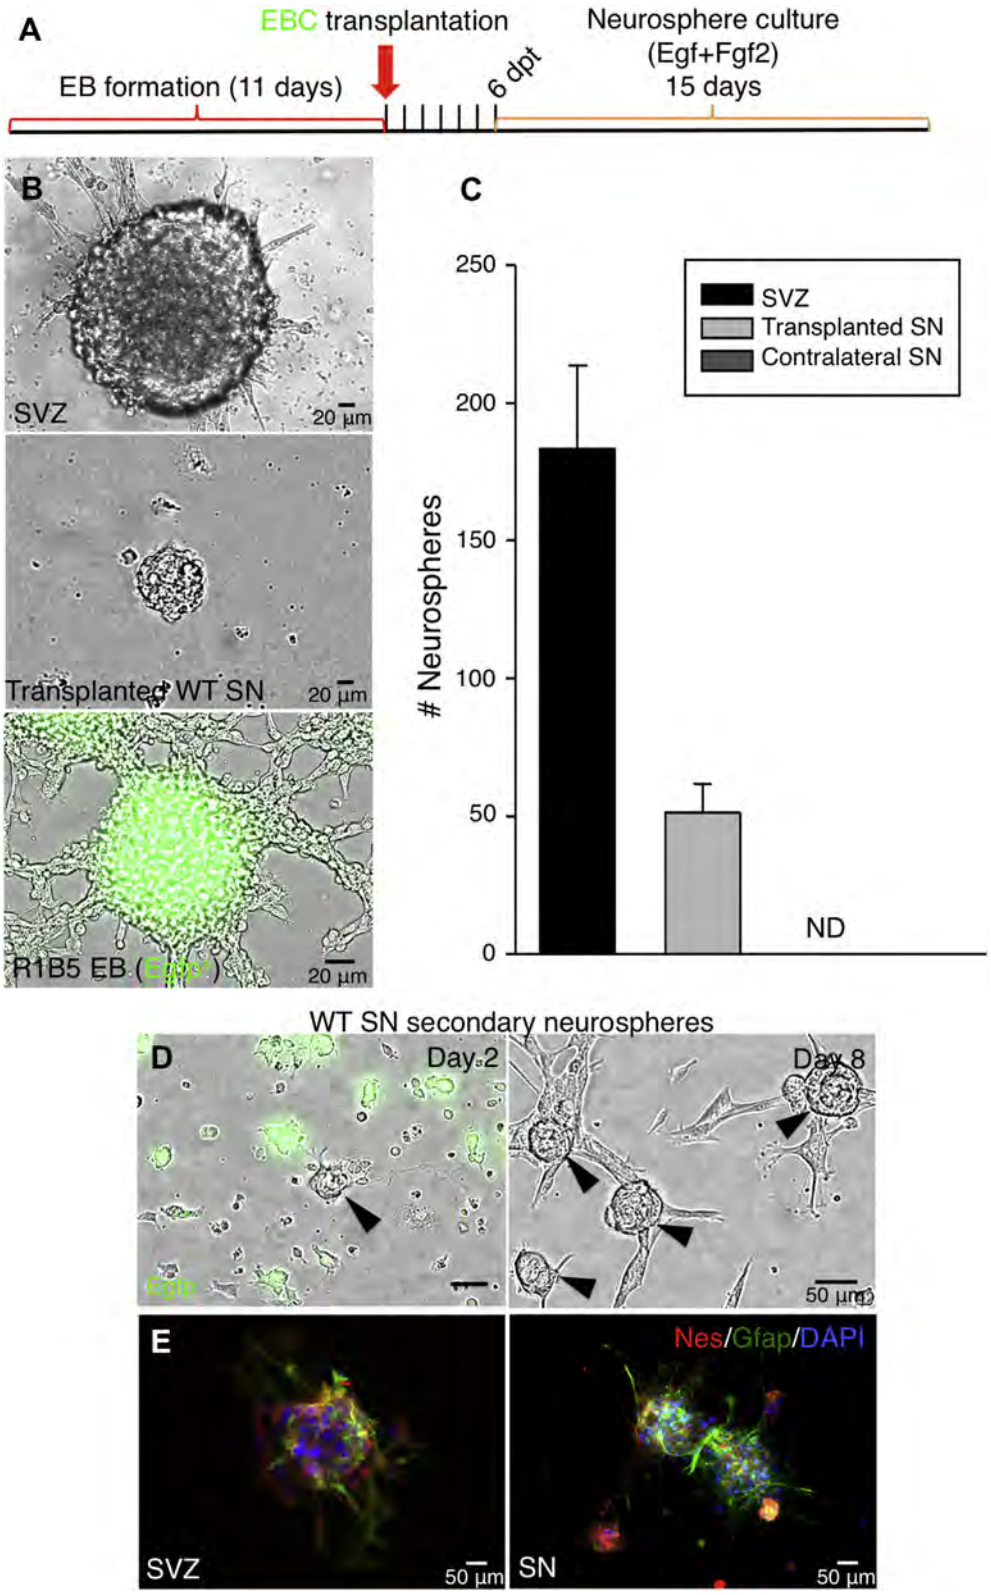

Fig. 4. Cells of the transplanted adult mouse SN generate neurospheres. (A) Schematic representation of the experimental strategy; transplanted EBCs were from R1B5 cells ($Egfp^+$). (B) Representative neurospheres from different cell sources: the SVZ (top) and the transplanted SN (middle). Note the formation of flat colonies derived from $Egfp^+$ EBCs (bottom). Scale bar 20 µm. (C) Number of neurospheres after 7 days *in vitro* for cells from the SVZ (positive control) and after 15 days *in vitro* for cells from the transplanted SN and contralateral SN (ND, not detected). Error bars indicate the SEM. (D) Secondary neurospheres (black arrowheads) formed from cells of the transplanted SN cultured for 2 or 8 days. (E) The SN neurospheres expressed *Gfap* and *Nes,* as typical neurospheres from the SVZ. Scale bar 50 µm.

INFORME DE LABORES 2019

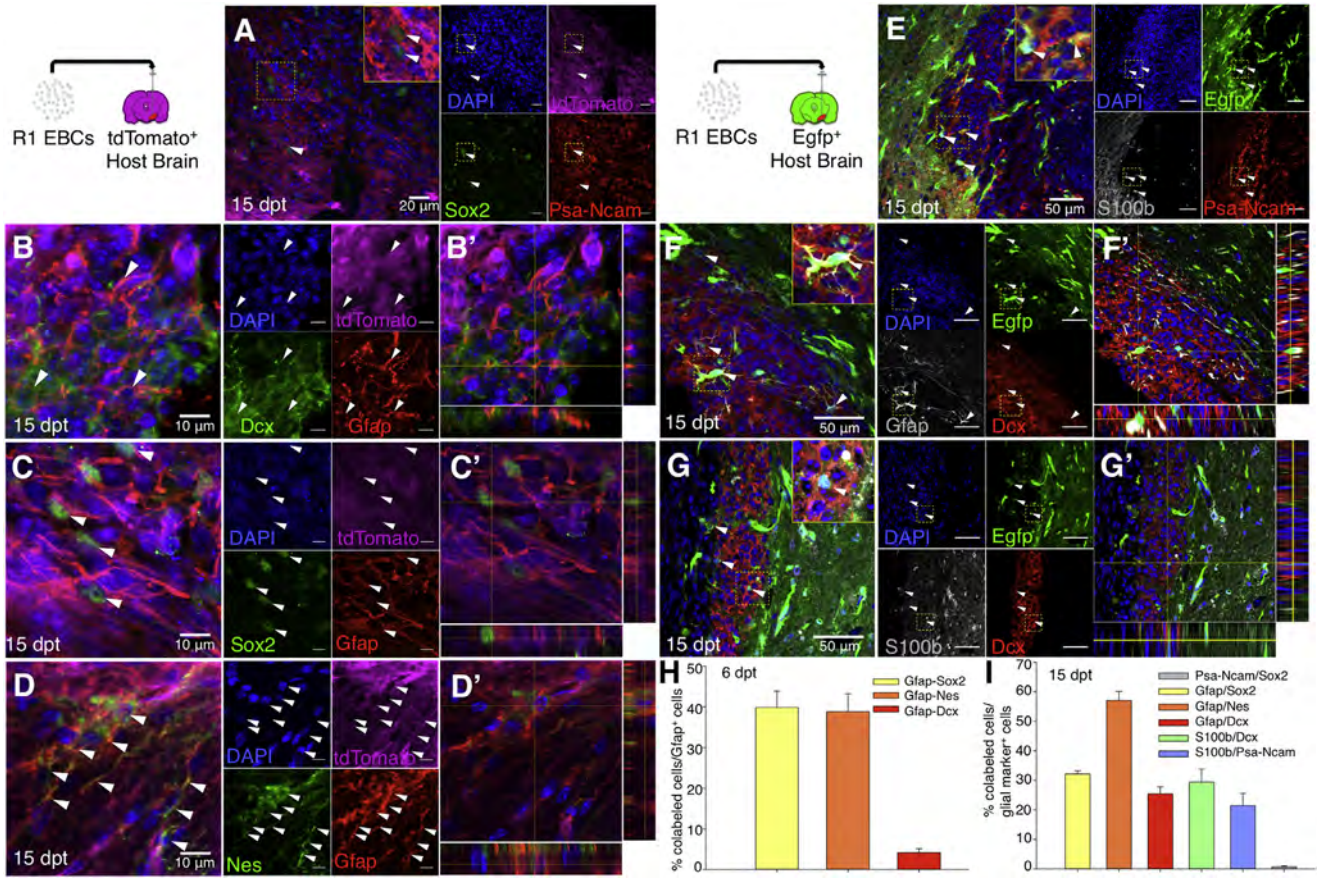

Fig. 5. Resident putative astrocytes express neuroblast and NPC markers after EBC transplantation. EBCs from R1 cells (no fluorescent marker present) were transplanted to the SN of tdTomato (A–D) mice or Egfp mice (E–G) and neural markers determined after 6 and 15 dpt. (A) Confocal Z-projection of Psa-Ncam$^+$/Sox2$^+$/tdTomato$^+$ cells at 15 dpt. (B–D) Confocal Z-projections showing host Gfap$^+$ cells (tdTomato$^+$) in the SN that colabeled with Dcx (B; B′, orthogonal view), Sox2 (C; C′, orthogonal view) and Nes (D; D', orthogonal view). Scale bar 10 µm. (E) Confocal Z-projection of S100b$^+$/Psa-Ncam$^+$/Egfp$^+$ cells at 15 dpt. (F, G) Confocal Z-projections showing host Gfap$^+$ (F) or S100b$^+$ (G) cells (Egfp$^+$) that colabeled with Dcx (F′ and G', orthogonal views). White arrowheads indicate colabeled cells. Scale bar 50 µm. (H) Percentage of colabeled Gfap$^+$/Sox2$^+$(n = 3), Gfap$^+$/Nes$^+$ (n = 3) and Gfap$^+$/Dcx$^+$ (n = 3) cells with respect to total host Gfap$^+$ cells at 6 dpt. (I) Percentage of colabeled Gfap$^+$/Sox2$^+$(n = 3), Gfap$^+$/Nes$^+$ (n = 3) and Gfap$^+$/Dcx$^+$ (n = 7) cells with respect to total Gfap$^+$ cells at 15 dpt. Additionally, the percentage of S100b$^+$/Dcx$^+$ (n = 7) and S100b$^+$/Psa-Ncam$^+$ (n = 3) is shown with respect to total S100b$^+$ cells and Psa-Ncam$^+$/Sox2$^+$ (n = 4) cells with respect to total Psa-Ncam$^+$ cells at 15 dpt.

process but only occurs under specific physiological conditions or damage.

Finding NSCs in regions with low neurogenic activity may not be an easy task, since they are expected to be scarce. Interestingly we found that, upon EBCs transplantation, dividing Sox2$^+$ and Nes$^+$ cells emerged in the SN. Migration of these cells from a putative neurogenic niche such as the aqueduct periventricular region seems unlikely since Sox2$^+$ cells were distributed evenly around the transplant and emerged only few days after transplantation. This kinetics is not in agreement with NPC migration from the aqueduct, a putative neurogenic niche that shows apparent capacity to populate the SN with new dopaminergic neurons 45–65 days after MPTP-induced injury (L'Episcopo et al. (2014). The identity of the dormant NSC found is uncertain since *Sox1*/*Sox2*/*Nes* expression was very infrequent in the intact SN; thus, common NSC markers may not be present or be expressed at low levels in these putative NSCs. In addition, although NSC markers appeared to emerge before cell division (detected as Sox1$^+$/Sox2$^+$/BrdU$^-$ NSCs), at least some of these 'activated' NSCs (Sox1$^+$/Sox2$^+$/BrdU$^+$) divide before differentiation into Dcx$^+$ neuroblasts (Dcx$^+$/BrdU$^+$) and neurons (NeuN$^+$/BrdU$^+$). Supporting the activation of quiescent NSCs, neurospheres could be generated from cells of the transplanted SN; interestingly, these neurospheres resemble those that can be generated from the SGZ (Guo et al., 2012). As in typical neurogenic regions, survival of terminally differentiated neurons was low and only few mature neurons were found. However, this outcome was also determined by the continuous growth of the transplant that made it difficult to track new neurons and determine the capacity for integration into established neuronal circuits.

EBC-induced neurogenesis involved the participation of blood vessels since the number of Dcx$^+$ neuroblast was reduced by an angiogenesis inhibitor and neurogenesis in the SN could also be induced by the infusion of angiogenic factors (i.e., Vegf and Fgf2). Interestingly, a strong association between NSCs and blood vessels has been observed in the SGZ (Palmer et al., 2000) and the SVZ (Shen et al., 2008). In agreement with a relevant role of this association,

INFORME DE LABORES 2019

the intracerebroventricular infusion of Vegf stimulates neurogenesis in these regions (Jin et al., 2002) and the ectopic expression of Vegf increases neurogenesis and blood vessels in the SGZ (Licht et al., 2016). Furthermore, as it appeared to occur in the SN, the simultaneous administration of Vegf and Fgf2 in the fourth ventricle activates a dormant NSCs population (Luo et al., 2015). In our experiments, the capacity of Fgf2 and Vegf for stimulating the generation of new neurons was lower than that of EBCs and, in addition, transdifferentiation from astrocytes to neurons appeared to occur at lower levels (see below); therefore, other factors secreted by EBCs contribute to promote the full neurogenic capacity of the SN.

Glial cells as a source of new neurons

NPC proliferation is a characteristic of activated neurogenesis such that new neuroblasts and neurons are typically identified by tracing the incorporation of nucleotide analogs. Therefore, it was unexpected to find that only around 20–30% of Dcx cells colabeled with BrdU, even when this latter nucleotide analog was constantly applied during most of the neurogenic process. This result suggests that these neuroblasts/young neurons do not emerge from highly dividing NPCs. In addition, many of those Dcx$^+$ and Psa-Ncam$^+$ neuroblasts colabeled with astrocytic markers such as Gfap and S100b. The presence of S100b was particularly relevant

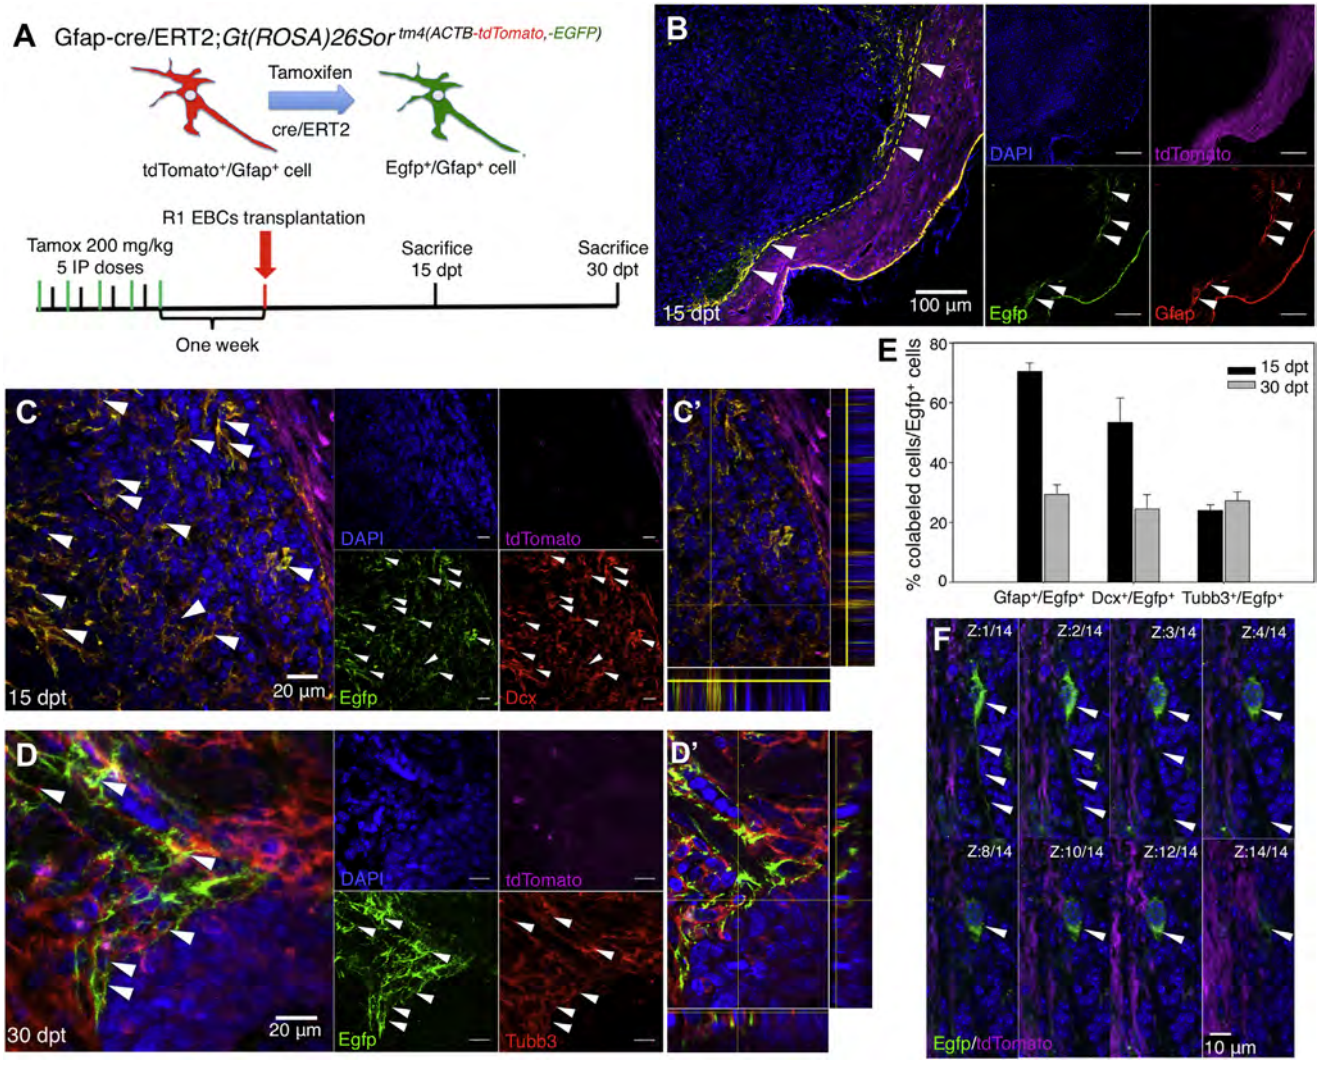

Fig. 6. Resident Gfap$^+$ cells acquire a neuronal fate after EBC transplantation to the SN. (A) Schematic representation of the experimental strategy. R1 EBCs (no fluorescent marker present) were transplanted to the SN of Gfap-cre/ERT2;*Gt(ROSA)26Sor* $^{tm4(ACTB\text{-}tdTomato,\text{-}EGFP)}$ double transgenic mice 1 week after tamoxifen treatment and neuronal markers determined at 15 and 30 dpt. (B) Confocal Z-projection showing the recombined cells Egfp$^+$/Gfap$^+$ (white arrowheads) around the transplantation site (dashed yellow line) at 15 dpt. (C) Dcx-labeled cells derived from Gfap$^+$ cells (Egfp$^+$; white arrowheads) at 15 dpt (C', orthogonal view). (D) Tubb3-labeled cells derived from Gfap$^+$ cells (Egfp$^+$; white arrowheads) at 30 dpt (D', orthogonal view). (E) Percentage of colabeled Gfap$^+$/Egfp$^+$, Dcx$^+$/Egfp$^+$, and Tubb3$^+$/Egfp$^+$ cells with respect to the total Egfp$^+$ cells at 15 and 30 dpt (n = 3–4). Error bars indicate SEM. (F) Z-plane trajectory of a representative Egfp$^+$ cell found around the transplantation site (30 dpt); note the projection that emerges from the cell body (white arrowheads).

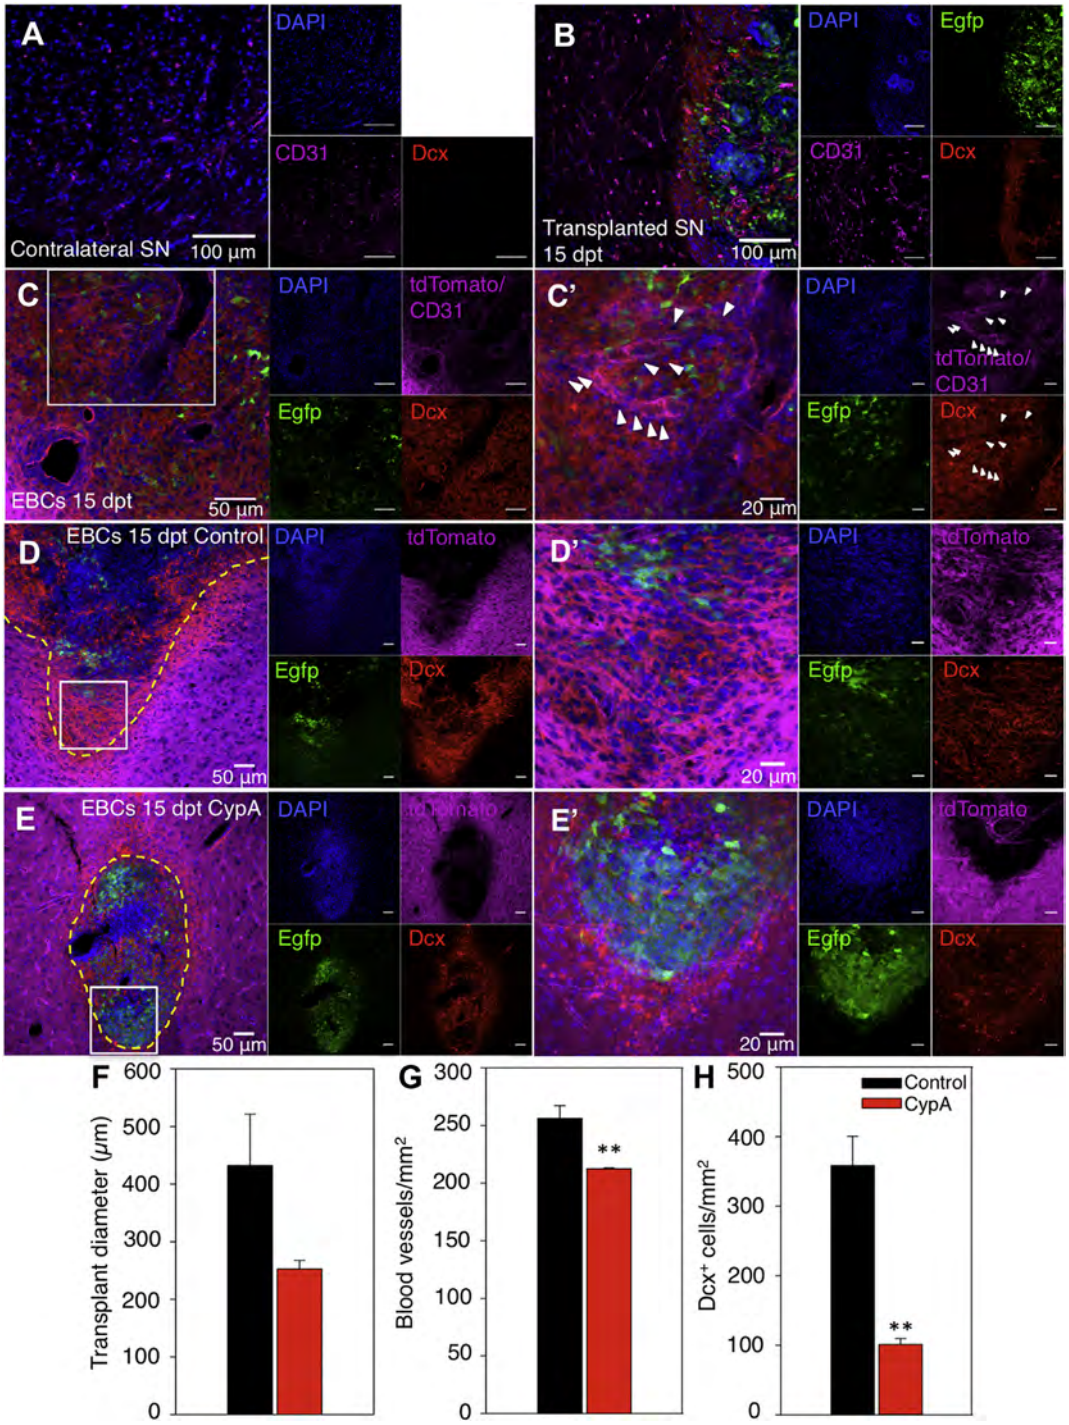

Fig. 7. Angiogenesis inhibition reduces transplant growth and induced neurogenesis in the SN. (A–B) R1B5 EBCs were transplanted to the SN of wild type mice. Dcx^+ cells were not found in the contralateral SN and CD31 immunoreactivity (magenta) appeared less evident (A), in comparison with the significant number of Dcx^+ cells (red) and blood vessels (magenta) in the SN with implanted EBCs (B). (C) Dcx^+ cells (red) were found tightly associated with $CD31^+$ blood vessels (magenta; white arrowheads in C'). (D–H) tdTomato mice previously transplanted with R1B5 EBCs ($Egfp^+$) were treated with CypA or injected with the vehicle solution (Control) and, after 15 dpt, the number of Dcx^+ cells generated was determined. (D) Confocal images showing neuroblasts (Dcx^+/$tdTomato^+$) surrounding the R1B5 EBC transplant ($Egfp^+$) in the tdTomato SN (magenta) at 15 dpt (Control). (E) Equivalent images from mice treated with CypA. Dcx^+ cells are shown in red and the transplant limited in picture by a yellow dashed line. Inset in (D) and (E) is shown in (D') and (E'), respectively. Determinations in the Control and CypA-treated mice of: (F) transplant diameter, (G) the number of blood vessels per mm^2, and (H) Dcx^+ cells per mm^2 are shown. Error bars indicate SEM; **$p < 0.01$.

INFORME DE LABORES 2019

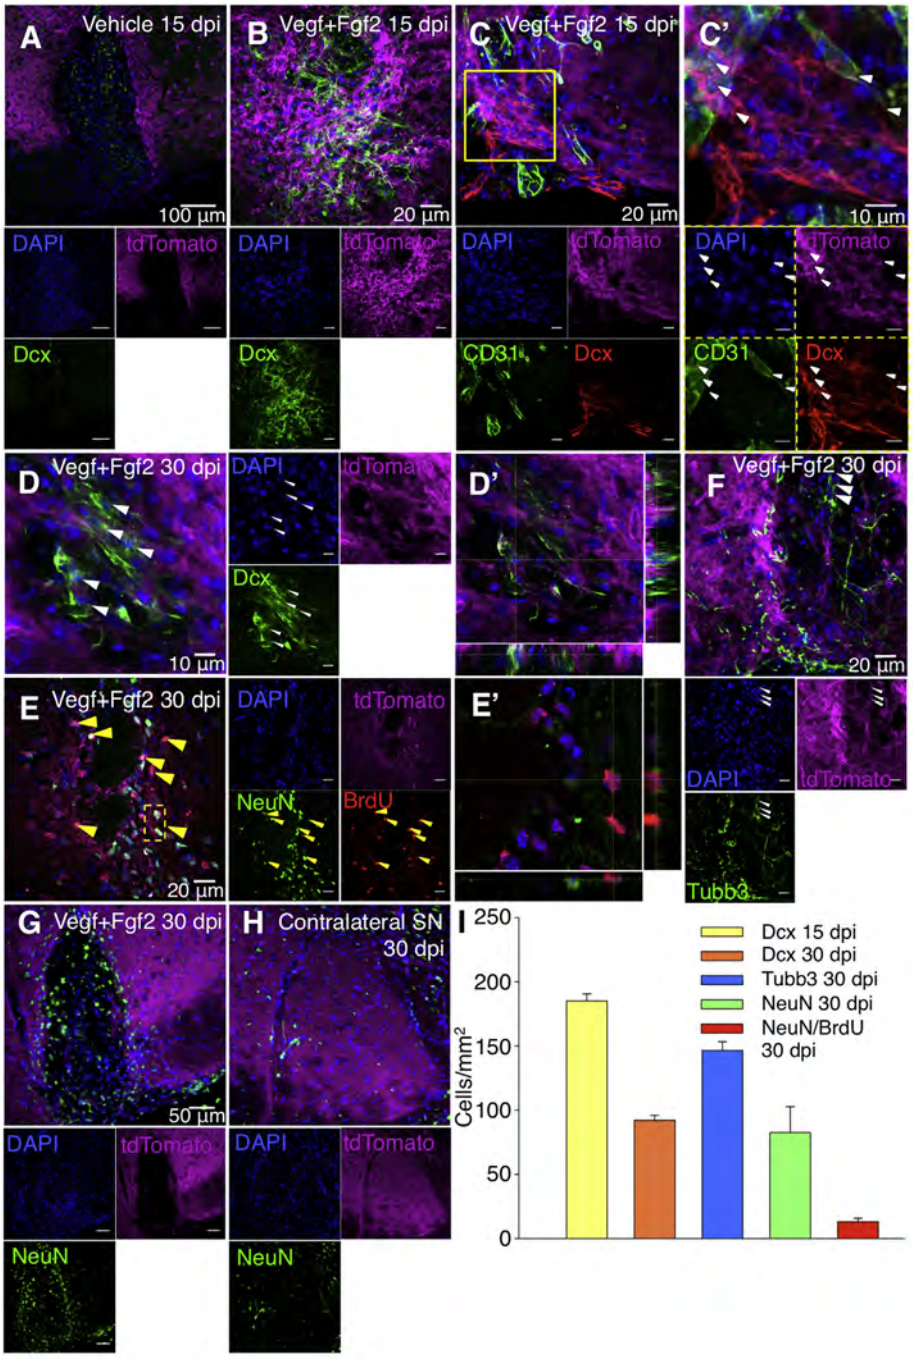

Fig. 8. Angiogenic factors promote neurogenesis in the SN. Vegf and Fgf2 were embedded in a Puramatrix hydrogel and then implanted in the SN of tdTomato mice; neuronal markers were determined at 15 and 30 dpi. (A, B) Confocal Z-projections showing the absence of Dcx^+ cells in the SN injected with a hydrogel without growth factors (Vehicle; A), and the presence of Dcx^+ cells emerging around the Fgf2 + Vegf-embedded hydrogel at 15 dpi (B). (C) Dcx^+ cells (red) are associated with thick blood vessels ($CD31^+$; green) in the Vegf+Fgf2 injected SN at 15 dpi (white arrowheads in C′ inset). (D, E) Confocal Z-projections showing Dcx^+ neuroblasts (D, white arrowheads; D', orthogonal view) and $NeuN^+$ cells (E; E', orthogonal view of inset in E) around the Vegf+Fgf2-embedded hydrogel in the SN of tdTomato mice at 30 dpi (n = 3–5); in E, yellow arrowheads indicate $NeuN^+$ cells that were also positive for BrdU. (F) Confocal Z-projection showing $Tubb3^+$ cells (white arrowheads) at 30 dpi. (G, H) $NeuN^+$ cells around the Vegf+Fgf2 injection site in the SN of tdTomato mice at 30 dpi (G) and in the contralateral non-injected SN (H); note that, although only 16% of the $NeuN^+$ cells were colabeled with BrdU, the density of NeuN labeled cells increased around the Vegf+Fgf2 containing hydrogel in comparison with the contralateral SN. (I) Quantification of labeled cells for the markers indicated (n = 3) near the injection site at 15 and 30 dpi is shown. Error bars indicate SEM.

since its gene is repressed in adult SVZ NSCs and is a chracteristic of 'mature' $Gfap^+$ astrocytes with reduced NSC properties (Raponi et al., 2007). It is relevant to mention that the level of Dcx detection in the SN was similar to the one obtained in the rostral migratory stream and the dentate gyrus (data not shown); thus these cells hardly correspond

INFORME DE LABORES 2019

to the ones previously reported in the SN (Worlitzer et al., 2013). Therefore, these results open the possibility that parenchymal Gfap$^+$ cells are transdifferentiating into neurons. Supporting this conclusion, lineage tracing in Gfap-cre/ERT2; *Gt(ROSA)26Sor* $^{tm4(ACTB-tdTomato,-EGFP)}$ double transgenic mice showed that Dcx$^+$ and Tubb3$^+$ cells can derive from Gfap$^+$ cells.

The conversion of astrocytes into neurons has been achieved by the forced expression of pro-neural factors such as neurogenin-2 and Ascl1 (Mash1) *in vitro* (Berninger et al., 2007) and *in vivo* (Torper et al., 2013;Rivetti di Val Cervo et al., 2017). However, the actual intrinsic potential of astrocytes for converting into neurons has been demonstrated mainly in the striatum after injury (Magnusson et al., 2014;Nato et al., 2015). In particular, Magnusson et al. (2014) showed that the conversion observed initiates by the downregulation of Notch1 signaling and the upregulation of *Ascl1*, and transits through cells that retain astrocytic markers (Gfap, S100b) at the time gain neuroblast markers (Dcx). This is similar to what we found in our study, though in this case, it is apparent that cell division is required before neuronal conversion (Fig. 10).

It is worth mentioning that early in the EBCs-induced neurogenesis, Gfap$^+$/Sox2$^+$ cells were abundant (6 dpt), but later (15 dpt) this population decreased while Gfap$^+$/Dcx$^+$ cells emerged. This contrasts with the increasing number of Gfap$^+$/Nes$^+$ cells which likely represent reactive astrocytes. Therefore, it is possible that non-dividing cells with NPC markers (Sox2$^+$/BrdU$^-$) emerge before becoming Dcx$^+$/Psa-Ncam$^+$ neuroblasts, and also that astrocytes are a candidate source of the dividing NPCs detected upon EBCs transplantation. Due to the sharing of phenotypic markers, complete discrimination of fully differentiated astrocytes from resident quiescent NSCs still requires further investigation. On the other hand, the infusion of Vegf and Fgf2 apparently was not as efficient as EBCs transplantation to induce the direct conversion of Gfap$^+$ cells into neuroblasts since few cells colabeled with markers of neuroblasts and astrocytes. However, not all neuroblasts/neurons appeared to originate from dividing NPCs, since few of these cells around the injected hydrogel incorporated BrdU along the neurogenic process. The astrocytic origin was supported by tracing Dcx$^+$ and Tubb3$^+$ cells from Egfp$^+$-labeled Gfap$^+$ cells. Therefore, a

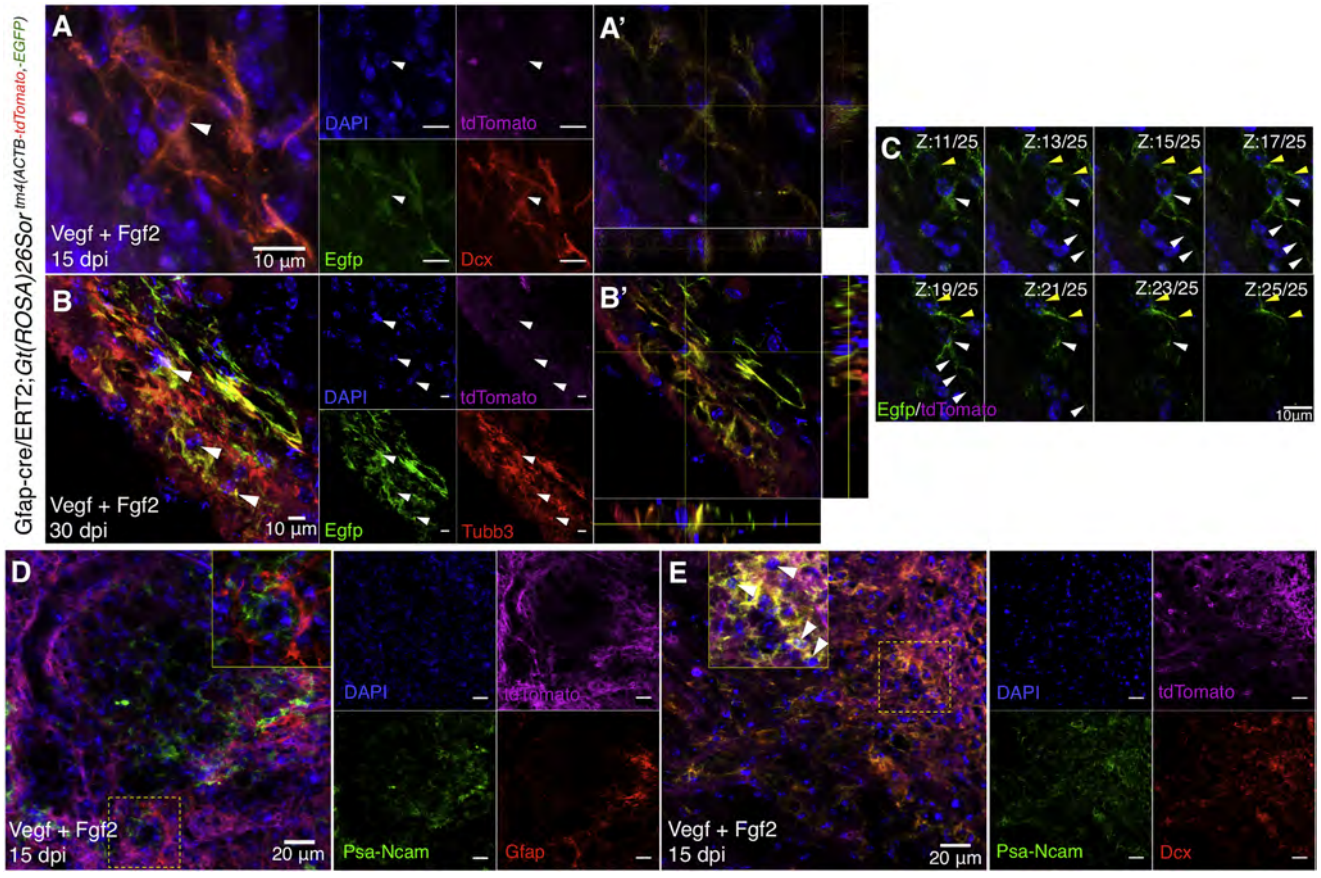

Fig. 9. Some SN putative astrocytes (Gfap$^+$ cells) derive into neurons in response to soluble angiogenic factors. The SN of Gfap-cre/ERT2;*Gt(ROSA)26Sor* $^{tm4(ACTB-tdTomato,-EGFP)}$ double transgenic mice, 1 week after tamoxifen treatment, was injected with a Fgf2 + Vegf-embedded hydrogel and neuronal markers determined at 15 and 30 dpi. (A) Some Dcx$^+$/Egfp$^+$ cells (white arrowheads; A', orthogonal view) were identified at 15 dpi. (B) Tubb3$^+$/Egfp$^+$ cells (white arrowheads; B′, orthogonal view) were identified at 30 dpi. (C) Z-plane trajectories of two representative Egfp$^+$ cells (white and yellow arrowheads) found around the implanted hydrogel (15 dpi); note the projections that emerge from the two cell bodies indicated. (D) Evaluation of the colabeling between Psa-Ncam and Gfap markers in neuroblasts detected around the injection site; only 4.56 ± 1.94% Psa-Ncam$^+$/Gfap$^+$ cells of total Psa-Ncam$^+$ cells were identified (n = 3). (E) Evaluation of the colabeling between Psa-Ncam and Dcx markers in neuroblasts detected around the injection site; colabeling (white arrowheads) was observed in most neuroblast identified (97.59 ± 2.58%; n = 3).

INFORME DE LABORES 2019

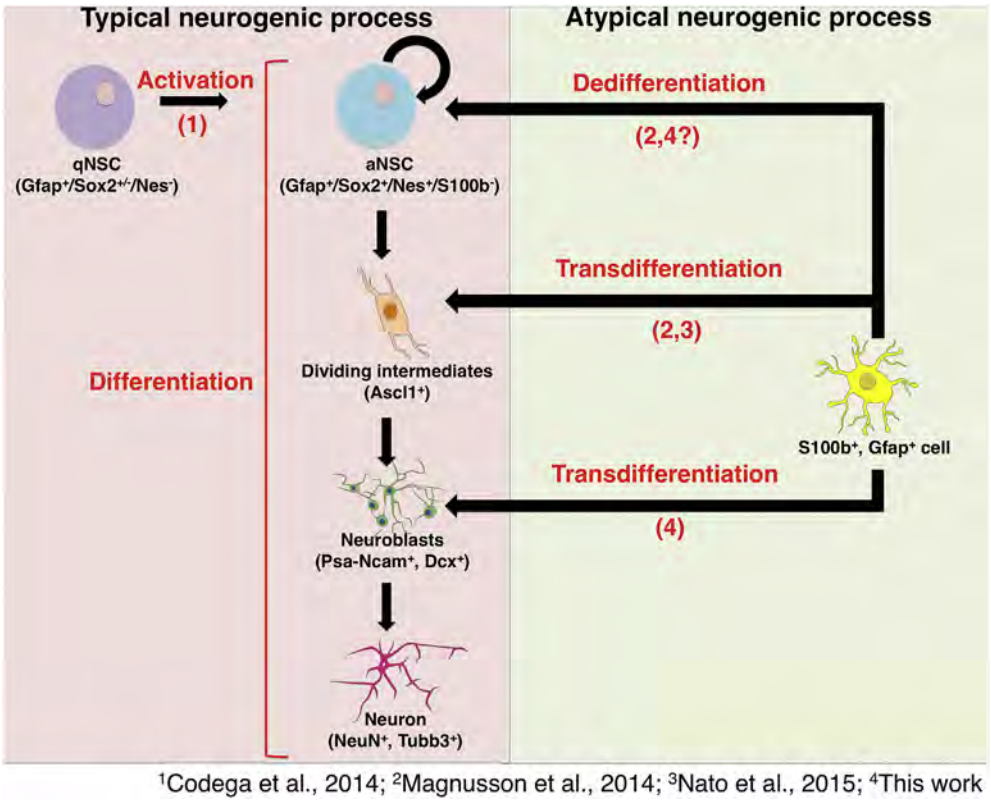

Fig. 10. Typical and atypical neurogenesis in the adult brain. A typical neurogenic process involves the participation of NSCs (aNSC) with self-renewal capacity, which give rise to highly dividing intermediates (Ascl1$^+$), which in turn originate new neuroblasts (Psa-Ncam$^+$/Dcx$^+$) that mature into fully differentiated neurons (Tubb3$^+$/NeuN$^+$). Regions with high neuronal renewal rate appear to have quiescent NSC-like cells (qNSC) that become active upon specific stimuli. In contrast with this typical neurogenic process, in the SN as well as in the striatum and medial cortex, cells with mature post-mitotic astrocytic markers (S100b$^+$/Gfap$^+$) can transdifferentiate or dedifferentiate into cells with neurogenic capacity upon certain inputs. These atypical neurogenic processes involve the acquisition by parenchymal astrocytes of NPC properties with or without the requirement of cell division. Whether these latter cells represent a specific class of quiescent NSCs remains to be determined (see text for details).

significant number of Tubb3$^+$ and NeuN$^+$ cells can emerge upon induction by either EBCs or Vegf+Fgf2 administration from non-dividing cells. Although we cannot discard that these are parenchymal astrocytes, an interesting possibility is that they are equivalent to the Gfap$^+$/S100b$^+$/Nes$^+$/Sox2$^+$ adult NSCs found in the intact zebrafish telencephalon, which are mostly quiescent and convert directly into neurons without a cell division phase (Barbosa et al., 2015).

Neurogenesis in the adult SN

Dopaminergic neurons might renew throughout life at a low rate and the process could be accelerated by induced neurodegeneration (e.g., disease-associated or provoked by a toxic compound). This perception derives from experimental observations whose interpretation is yet inconclusive. One issue that remains to be determined is the origin of these new neurons. BrdU incorporation has been detected during the generation of new dopaminergic neurons in the adult SN (Zhao et al., 2003). Without considering the possibility of BrdU incorporation due to a DNA repair process, this has been interpreted as an indicative of the presence of NPCs in the SN though, strictly, this only indicates that, during the process of renewal or repair, cell divisions occur. In another study, based on the tracing of dopaminergic neurons with deleted floxed *Th* alleles due to the activation in the adult of CreER, whose expression was driven by either the Nes or Sox2 promoter, it was proposed that the source of new dopaminergic neurons are cells Nes$^+$/Sox2$^-$ (Albright et al., 2016). We have not been able to detect Nes$^+$ cells within the intact SN, thus leaving the possibility that these precursors are recruited from "nearby" neurogenic sites [e.g., periaqueduct; L'Episcopo et al., 2014]. Alternatively, transient *Nes* expression could have occurred in putative active precursors in the SN during tamoxifen treatment as it occurs in some striatal astrocytes (Nato et al., 2015).

Here we show that scarce dividing cells or cells with NPC markers were present in the intact SN, but cells with NPC or neuroblast markers rapidly emerge upon EBCs transplantation or Vegf+Fgf2 infusion. However, although these cells showed neurogenic capacity, expression of the essential *Th* dopaminergic gene and of genes required for mesencephalic dopaminergic differentiation (i.e., *Lmx1a*, *Neurog2*; Guerrero-Flores et al., 2017) was not found in neuronal derivatives at any time. The inability of the precursors identified here for deriving new dopaminergic neurons might be due to an inhibitory effect of EBCs-secreted factors or missing factors required for correct specification not activated under the conditions tested. In this regard, it will be interesting to determine whether the missing factors activate upon induced

dopaminergic neurodegeneration though, at the moment, it cannot be discarded that the neuronal fate of activated NPCs is restricted to non-dopaminergic phenotypes.

Homeostatic renewal of neurons has been proposed for many brain regions, including the striatum and the SN. However, an evident neurogenic niche has not been found in these regions. On the other hand, it has been proposed that a neurogenic process activates upon injury. Our data support that new neurons can originate in the SN from either dormant NSCs or parenchymal astrocytes that upon a transdifferentiation phenomenon are converted into NPCs or directly into neuroblasts (Fig. 10). However, our data do not provide evidence on the adult SN capacity to generate new dopaminergic neurons. Due to the biological and medical interest, ongoing work is focused to determine whether SN glial cells could be the source of new dopaminergic neurons.

Glossary

Adult Neurogenesis*:* Process by which new mature and functional neurons are generated in the brain of adult animals.

Dedifferentiation*:* Process by which a differentiated and specialized cell regresses to an undifferentiated state, as a progenitor or stem cell.

Embryoid bodies*:* ESC aggregations formed *in vitro* that emulate the early developmental stage of embryo gastrulation. It is used to promote ESC differentiation into ectodermal, mesodermal and endodermal cells.

Transdifferentiation*:* Conversion of one fully differentiated cell into another cell type without undergoing a proliferation step.

The intracellular domain of β-dystroglycan mediates the nucleolar stress response by suppressing UBF transcriptional activity

Abstract

β-dystroglycan (β-DG) is a key component of multiprotein complexes in the plasma membrane and nuclear envelope. In addition, β-DG undergoes two successive proteolytic cleavages that result in the liberation of its intracellular domain (ICD) into the cytosol and nucleus. However, stimuli-inducing ICD cleavage and the physiological relevance of this proteolytic fragment are largely unknown. In this study we show for the first time that β-DG ICD is targeted to the nucleolus where it interacts with the nuclear proteins B23 and UBF (central factor of Pol I-mediated rRNA gene transcription) and binds to rDNA promoter regions. Interestingly DG silencing results in reduced B23 and UBF levels and aberrant nucleolar morphology. Furthermore, β-DG ICD cleavage is induced by different nucleolar stressors, including oxidative stress, acidosis, and UV irradiation, which implies its participation in the response to nucleolar stress. Consistent with this idea, overexpression of β-DG elicited mislocalization and decreased levels of UBF and suppression of rRNA expression, which in turn provoked altered ribosome profiling and decreased cell growth. Collectively our data reveal that β-DG ICD acts as negative regulator of rDNA transcription by impeding the transcriptional activity of UBF, as a part of the protective mechanism activated in response to nucleolar stress.

Introduction

Regulated proteolysis of cell surface receptors that liberates biologically active proteins/peptides from the plasma membrane (PM) to the cytosol is a critical step in a variety of different signaling pathways that respond to external stimuli. γ-Secretase is an intramembranous cleaving protease complex consisting of at least four proteins: presenilin-1, nicastrin, anterior pharynx-defective phenotype 1, and presenilin enhancer 2[1]. γ-Secretase is known to be required for the activation of many transmembrane proteins, including the amyloid precursor protein, cadherins, Notch1[2], and recently, dystroglycan[3,4]. Dystroglycan, a key component of the dystrophin-associated protein complex (DAPC), is transcribed from the *DAG1* gene and translated as a single propeptide, which is proteolytically processed to generate the extracellular subunit α-dystroglycan (α-DG) and the transmembrane subunit β-dystroglycan (β-DG)[5]. α-DG binds to different extracellular matrix proteins

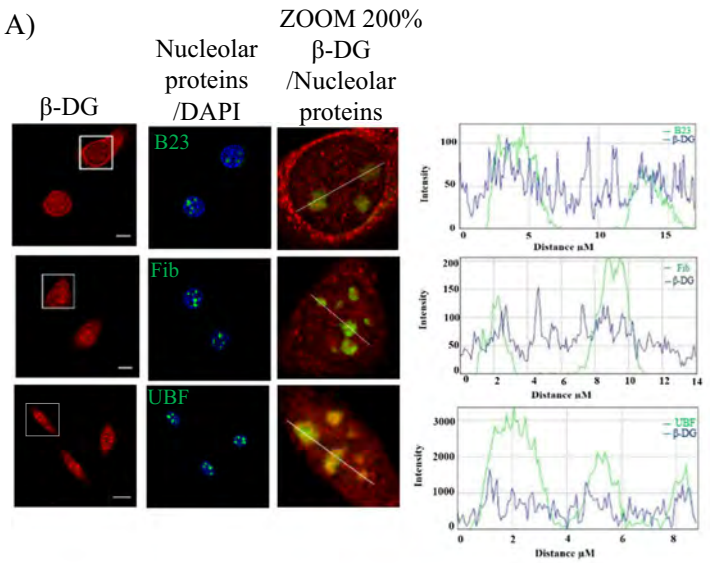
INFORME DE LABORES 2019

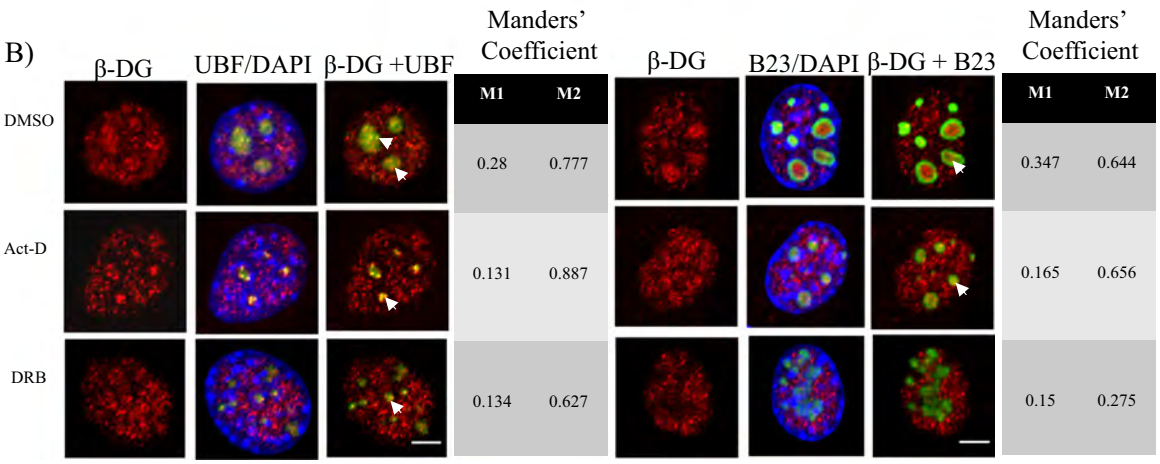
including laminin, agrin, or perlecan[6], while β-DG connects actin through various cytolinker proteins including dystrophin or utrophin. Thereby, dystroglycan serves as a link between the extracellular matrix and the actin-based cytoskeleton, acting also as an adhesion and signaling receptor[5,7].

Besides its structural role in the maintenance of membrane integrity, dystroglycan localization is not static but dynamic. Phosphorylation of β-DG at Y^{890} triggers its retrograde trafficking from PM to the nucleus, via the membranous endosome-endoplasmic reticulum (ER) network, with ezrin activation enhancing the intracellular trafficking and translocon Sec61 facilitating the exit of β-DG from the ER membrane to be accessible for importin-dependent nuclear import through the nuclear pore[8–10]. In the nucleus, β-DG is assembled with nuclear envelope (NE) components, including emerin, and lamins A/C and B1, to preserve the nuclear structure/function[11,12] and where it can also indirectly regulate gene expression[13]. This functional diversity of β-DG, acting as a platform for both PM- and NE-associated processes, is further expanded by proteolytic cleavage of the protein. β-DG is subjected to proteolytic cleavage by MMP-2 and MMP-9 to liberate its extracellular domain[14,15], while the remaining fragment, containing the transmembrane stub and the cytoplasmic portion is thought to be subsequently processed by γ-secretase to deliver an intracellular domain (ICD; 12 kDa in mass but runs aberrantly on SDS-PAGE at ~26 kDa) into the cytosol[3,4]. Recent evidence showed that β-DG ICD is targeted to the nucleus in prostate cancer cells[3,13,16] nonetheless the biological significance of such localization is largely unknown. The nucleus is organized into distinct functional compartments containing specific macromolecules that govern nuclear processes;[16] for instance, the nucleolus is a prominent non-membranous nuclear organelle primarily involved in ribosome biogenesis and cellular homeostasis[17]. Thus, identification of the destination of β-DG ICD within the nucleus could facilitate further elucidation of its function.



In this study we demonstrate for the first time that β-DG ICD is target to the nucleolus where it plays a negative role in the regulation of ribosomal RNA (rRNA) transcription. We provide evidence that full-length β-DG is proteolytically processed into β-DG ICD in response to nucleolar stress, via the Notch signaling pathway. Remarkably, β-DG ICD binds to the rDNA promoter to suppress rRNA synthesis by impairing the expression, localization, and ultimately activity of the RNA polymerase I (Pol I) transcription factor UBF (upstream binding factor), which further results in the down-regulation of rRNA expression and cell proliferation. Thus, β-DG ICD appears to be a key contributor to the nucleolar stress response.

Results



The γ-secretase-generated intracellular domain of β-DG is targeted to the nucleolus

We previously observed localization of β-DG to the nucleoli in C2C12 myoblasts[11]; but no role for β-DG has been described in this nuclear organelle. As a first step, we analyzed whether β-DG colocalizes with proteins that define functionally distinct compartments of the nucleolus. Cells were double-stained for β-DG (C20 antibody) along with UBF, fibrillarin (markers of the fibrillar center, FC), or B23 (marker of the granular component, GC) and further analyzed by confocal microscopy. The nucleolar immunostaining of β-DG colocalized at certain extent with all three nucleolar proteins analyzed, as confirmed by the line intensity scan analysis and Manders' overlapping coefficients (Fig. 1a). The specificity of C20 antibody was demonstrated using both DG knockout C2C12 cells and primary fibroblasts from a subject with Walker–Warburg syndrome that do not express *DAG1* gene all[18]. Nucleoli were strongly staining by C20 in C2C12 wild-type cells, while a faint nuclear staining that was excluded from nucleoli was observed in DG knockout C2C12 cells (Supplementary Figure 1A, left panel). Furthermore, the immunoreactive band corresponding to β-DG (~43 kDa), which was observed in primary fibroblast lysates from a healthy subject, was absent in Walker–Warburg syndrome primary fibroblast lysates (Supplementary Figure 1A, right panel). Finally, pre-incubation with a blocking peptide virtually eliminated C20 immunostaining in wild-type cells (Supplementary Figure 1B). In addition, nucleolar localization of β-DG was confirmed using another anti-β-DG antibody (G5; Supplementary Figure 1C). The nucleolus is a highly dynamic organelle that responds to a variety of cellular stresses with morphological changes[19] and redistribution of proteins implicated in ribosome biogenesis form perinuclear caps upon inhibition of rDNA transcription[20]. C2C12 cells were therefore treated with actinomycin D (0.08 μg/ml) or DRB (0.3 μM) to cause nucleolar stress, and the effect of treatments on β-DG distribution was evaluated by confocal microscopy. The formation of nucleolar caps and nucleolar segregation/nucleolar necklaces was found after treatment with Act D and DRB, respectively, as shown by immunostaining for UBF and B23 (Fig. 1b). Treatment with the vehicle alone dimethyl sulfoxide (DMSO) produced no change in the immunostaining pattern of nucleolar proteins. Interestingly, nucleolar labeling of β-DG also underwent redistribution in response to Act D and DRB but remained in colocalization partially with UBF and barely with B23, as shown by Manders' overlapping coefficient analysis (Fig. 1b), suggesting that β-DG might be involved in nucleolar organization/plasticity. Next, we investigated whether the nucleolar localization of β-DG is dependent on nucleic acid integrity. C2C12

Fig. 1 β-DG colocalizes with nucleolar proteins before and after induced nucleoli disorganization. a C2C12 cells were double immunostained for β-DG (C20 antibodies) and B23, fibrillarin (Fib), or UBF. Cells were stained with DAPI for nuclei visualization prior to being subjected to confocal laser scanning microscopy (CLSM; scale bar = 5 μm). Colocalization of β-DG with nucleolar proteins is denoted by arrowheads in the magnified images. A line intensity scan along the white line in the merge images was carried using ROI manager Multiplot (middle graphs). *Right*: The Manders overlap coefficient was calculated on double labeling inmunofluorescences: M1 denotes the fraction of the β-DG signal coincident with the nucleolar proteins signal over its total intensity, and M2 denotes the fraction of the nucleolar proteins signal coincident with the β-DG signal over its total intensity. **b** Cells were treated with actinomycin D (Act D) or DRB for 3 h, fixed and then double immunostained for β-DG and either UBF or B23. Nuclei were stained with DAPI before CLSM analysis (scale bar = 1 μm). Typical single Z-sections are shown and colocalization of β-DG with nucleolar proteins after drug-induced nucleoli disruption is indicated by arrowheads in the merge images. The Manders overlap coefficient was calculated for each experimental condition as peer **a**

myoblasts were immunolabeled for β-DG before and after nuclease treatment, and stained with DAPI to monitor DNA degradation, or immunolabeled for hnRNP C1/C2 antibody (RNA-binding protein) to monitor RNA removal. DNase digestion completely removed DAPI-labeled DNA, while treatment with RNase caused hnRNP C1/C2 redistribution from the nucleoplasm to the nuclear periphery and cytoplasm, thus confirming the effectiveness of nucleases treatment. DNase treatment completely abrogated the nucleolar distribution of β-DG, while treatment with RNase apparently increased the intensity of β-DG nucleolar immunostaining, compared with untreated cells (Supplementary Figure 2A and B). These results suggest that the nucleolar localization of β-DG is dependent on DNA.

To demonstrate conclusively that β-DG resides in the nucleolus, C2C12 were fractionated into total, cytoplasmic, nuclear, and nucleolar fractions to be further analyzed by SDS-PAGE/WB. A prominent ~30 kDa β-DG band was found enriched, together with fibrillarin, in the

INFORME DE LABORES 2019

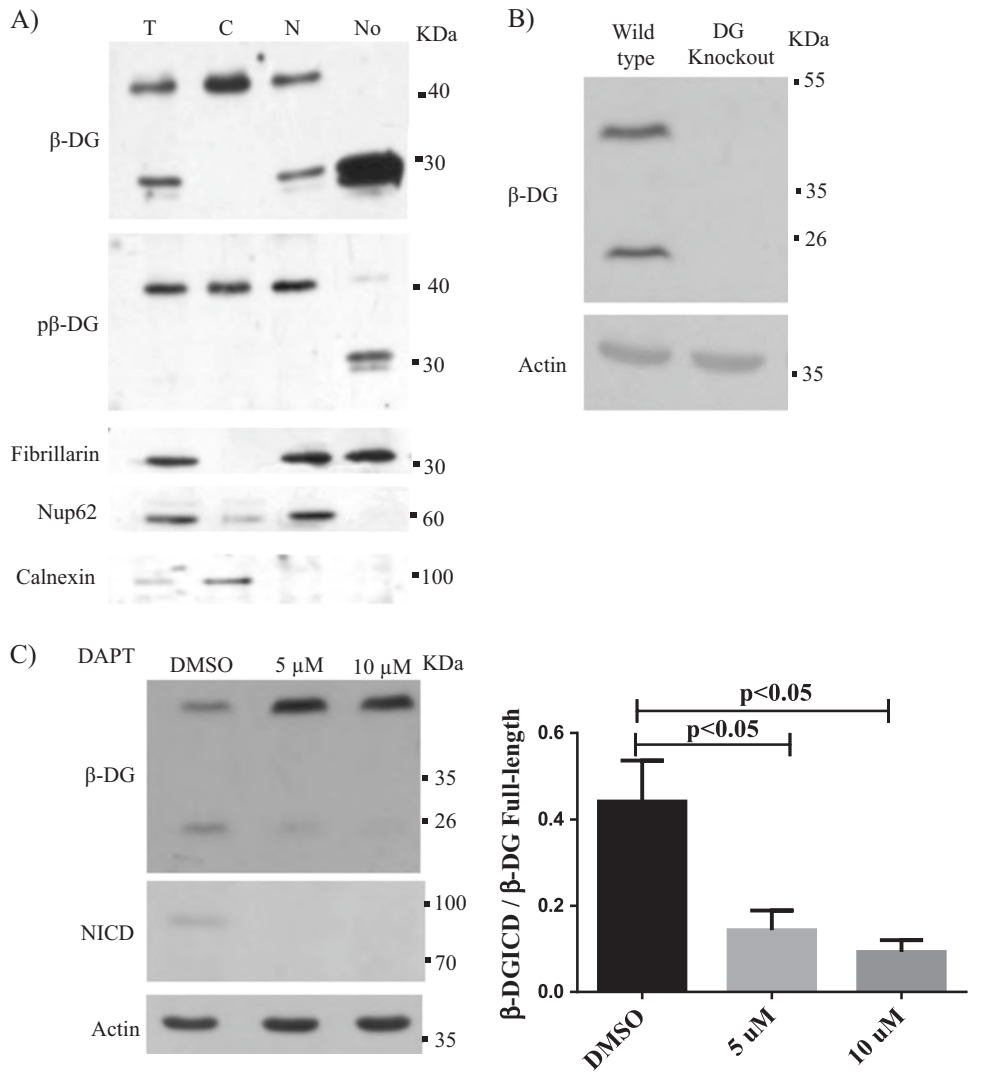

Fig. 2 β-DG ICD resides in the nucleolus. a Cells were partitioned to obtain total (T), cytoplasmic (C), nuclear (N), and nucleolar (No) fractions, prior to SDS-PAGE/WB analysis, using specific antibodies for β-DG (Mandag) or its phosphorylated counterpart (pβ-DG). Fibrillarin (nucleolar protein), Nup62 (nuclear membrane protein), and calnexin (reticulum endoplasmic protein) were used as cellular fraction markers. **b** Lysates from wild-type and DG knockout C2C12 cells were analyzed by SDS-PAGE/WB using antibodies for β-DG (Mandag) and actin (loading control), to demonstrate β-DG antibody specificity. **c** Lysates from C2C12 cells treated for 24 h with the indicated concentrations DAPT (γ-secretase inhibitor) or the vehicle alone (DMSO) were analyzed by SDS-PAGE/WB, using antibodies for β-DG, Notch intracellular domain (NICD; positive control for DAPT action), and actin (loading control). Representative gel from three independent experiments is shown. *Right*. Data correspond to the mean ± SEM from three independent experiment, with *p* values indicating significant differences (unpaired *t*-test)

nucleolar fraction, as revealed using three different anti-β-DG antibodies: MANDAG (mouse mab that recognizes total β-DG levels), pTyr890 (rabbit pAb that specifically recognizes β-DG phosphorylated at Tyr^{890}) (Fig. 2a), and C20 (rabbit antibody that recognizes the total β-DG pool Supplementary Figure 1D). Nup62 (nuclear pore protein) and calnexin (endoplasmic reticulum protein) were recovered in the nuclear and cytoplasmic fractions, respectively, and the two proteins were absent from the nucleolar fraction demonstrating that no cross-contamination occurred during cellular fractionation. Control experiments using both DG knockout C2C12 cells and Walker–Warburg syndrome primary fibroblasts yield no immunoreactive bands after incubation with MANDAG antibody (Fig. 2b and Supplementary Figure 1A, right panel), which demonstrated the specificity of this antibody for β-DG detection. We hypothesized that the ~30 kDa band correspond to the ICD of β-DG generated by γ-secretase cleavage as has been described previously[3,13,16]. Compatible with this assumption, lysates from cells treated with DAPT (γ-secretase inhibitor) resulted in a dose-dependent decrease in β-DG ICD levels that paralleled with

INFORME DE LABORES 2019

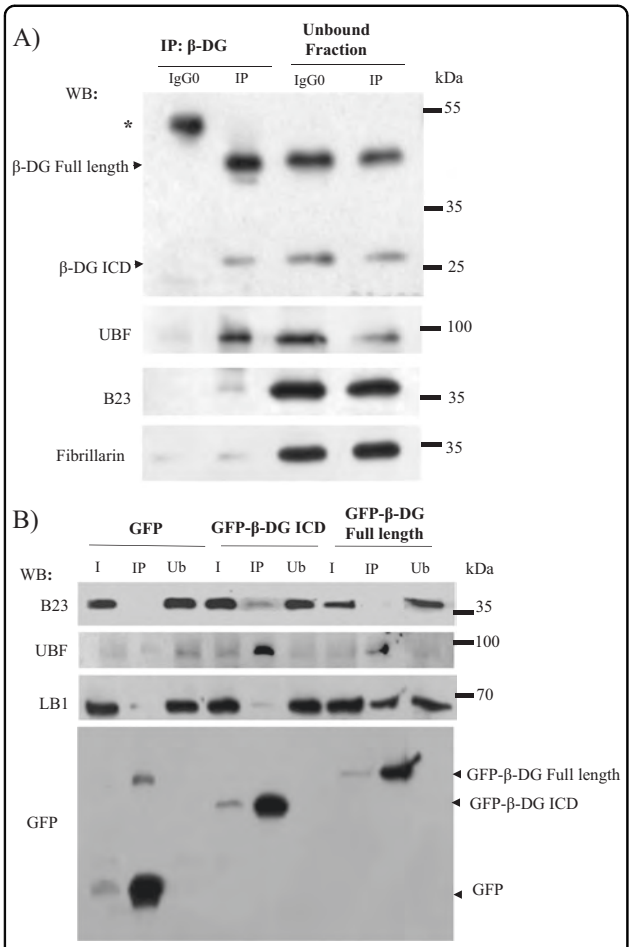

Fig. 3 β-DG ICD interacts with the nucleolar proteins UBF and B23. a C2C12 cell lysates were subjected to immunoprecipitation (IP) using anti-β-DG antibody (Mandag) and the precipitated proteins were subsequently analyzed by western blotting using primary antibodies against β-DG, UBF, B23, or fibrillarin. **b** Lysates from cells transiently expressing GFP-β-DG full-length, β-DG ICD, or GFP alone were subjected to immunoprecipitation using the GFP-Trap system, and the captured proteins were analyzed by western blotting using antibodies against B23, UBF, lamin B1 (LB1), and GFP. **a**, **b** Ub, unbound proteins, IP immunoprecipitated fraction, IgG0, nonspecific antibody. Input corresponds to 10% of protein lysates prior to immunoprecipitation

dose-dependent reduction of the intracellular domain of Notch (NICD), a well-characterized γ-secretase substrate (Fig. 2c). Collectively these data support the idea that the γ-secretase-derived cleavage fragment of β-DG (~30 kDa), named hereafter as β-DG ICD, is targeted to the nucleolus where it possibly has a role in regulating nucleoli structure/function.

β-DG ICD interacts with UBF and B23

Colocalization of β-DG with nucleolar proteins even after induced nucleolar disruption (Fig. 1b), suggests their physical interaction. Consistent with this notion, UBF and traces of B23 but not fibrillarin were recovered in complex with β-DG after immunoprecipitation (IP) of C2C12 lysates with anti-β-DG antibody (Fig. 3a). None of the nucleolar proteins were immunoprecipitated using non-specific IgG antibodies. Because anti-β-DG antibody immunoprecipitated both β-DG full-length and β-DG ICD, we wondered what form is bound to nucleolar proteins. To approach this, C2C12 cells were transiently transfected to express GFP-β-DG full-length or GFP-β-DG ICD and subjected to GFP-based IP assays. Both UBF and B23 were found preferentially bound to GFP-β-DG ICD, with UBF interaction predominant over that with B23 (Fig. 3b). GFP alone interacted with neither B23 nor UBF, while lamin B1 (β-DG nuclear partner) was bound to GFP-β-DG full-length but not GFP-β-DG ICD, demonstrating the specificity of GFP-Trap assays.

Silencing of DG disrupts nucleolar morphology and decreases B23 and UBF levels

To elucidate whether nucleolar localization of β-DG is physiologically relevant, the impact of knocking down of β-DG expression on nucleolar structure and expression of nucleolar proteins was examined. Significant reduction of dystroglycan mRNA levels and the consequent decrease in β-DG full-length and β-DG ICD levels were observed upon stably transfection of C2C12 cells with a vector expressing a short hairpin RNA against *DAG1* gene (DG shRNA), compared to cells expressing an unspecific shRNA (control shRNA) (Fig. 4a, b). Remarkably, the depletion of β-DG resulted in decreased proteins levels of B23 (80%), fibrillarin (30%), and UBF (60%) (Fig. 4b). Such effects were accompanied by a clear alteration in nucleolar morphology; while control shRNA cells contain numerous relatively small nucleoli, β-DG-depleted cells exhibited fewer larger and more amorphous nucleoli, as shown by immunostaining for UBF and B23 (Fig. 4c, d) and quantification of nucleolar area (right panels).

β-DG binds to the rDNA promoter to possibly regulate rRNA expression

Because knockdown of β-DG resulted in decreased levels of UBF, a key component of the RNA polymerase I preinitiation complex in rRNA transcription, we sought to determine the expression of 28 S and 18 S pre-rRNAs in β-DG knockdown cells by quantitative RT-PCR (Figure 4a). β-DG knockdown cells exhibited an ~40% decrease in 18 S levels, while 28 S expression showed a slight but significant increase, compared with control shRNA (Fig. 5a). To provide insight into the mechanism by which β-DG depletion influences rDNA gene expression, we analyzed whether β-DG is physically associated with the rDNA promoter. Chromatin was immunoprecipitated from wild-type and DG knockout (negative control) C2C12 cells, using β-DG or nonspecific IgG

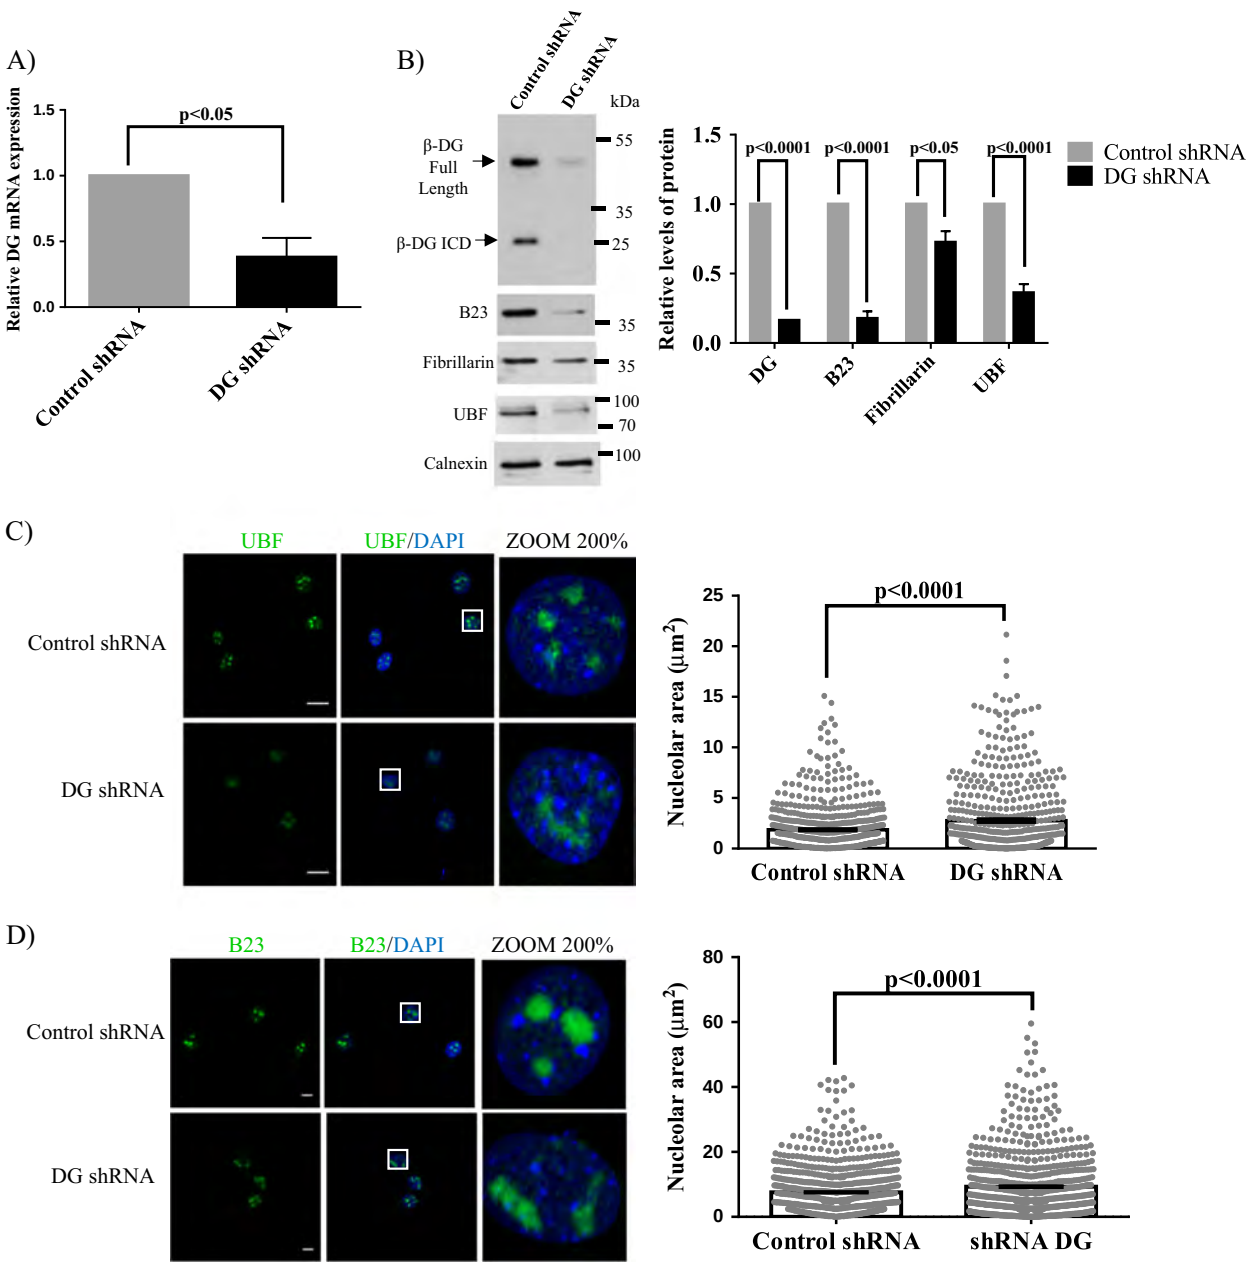

Fig. 4 Silencing of dystroglycan results in altered nucleoli structure and reduced levels of B23 and UBF. a Messenger RNA expression of dystroglycan and GAPDH (endogenous control) was assessed by qRT-PCR in C2C12 cells stably expressing DG shRNA or control shRNA, as described in Methods. Relative mRNA levels obtained in control cells were set at 1. Results are the mean ± standard deviation of three independent experiments, with *P* value indicating significance difference (unpaired *t*-test). **b** Lysates from C2C12 cells stably transfected with DG shRNA or control shRNA were analyzed by western blotting using primary antibodies against DG, B23, fibrillarin, UBF, and calnexin (loading control). Blots were stripped and reprobed successively with each protein antibody. Relative protein levels from control shRNA cells were set at 1 for comparison. Results are the mean ± SEM of three independent experiments (right panel), with *p* value denoting significance differences (unpaired *t*-test). **c**, **d** Nucleolar morphology was analyzed in cells stably expressing DG shRNA or control shRNA, using specific antibodies against UBF and B23 respectively. Cells were counterstained with DAPI to visualize nuclei prior to CLSM analysis. The nucleolar area (μm^2) was determined in each cell condition as described in Methods (graphs at right). Data are the mean ± SEM from three independent experiments ($n = 600$ nucleoli), with *p* values indicating significant differences (unpaired *t*-test)

antibodies; moreover, ChIP assays using RNA polymerase I (Pol I) antibodies were performed in parallel (positive control). Then, rDNA was amplified using primers specific for the rDNA promoter, 5.8 S or intergenic spacer (IGS) regions. ChIP assays revealed the presence of β-DG in the 5.8 S and IGS regions, while Pol I was found to

INFORME DE LABORES 2019

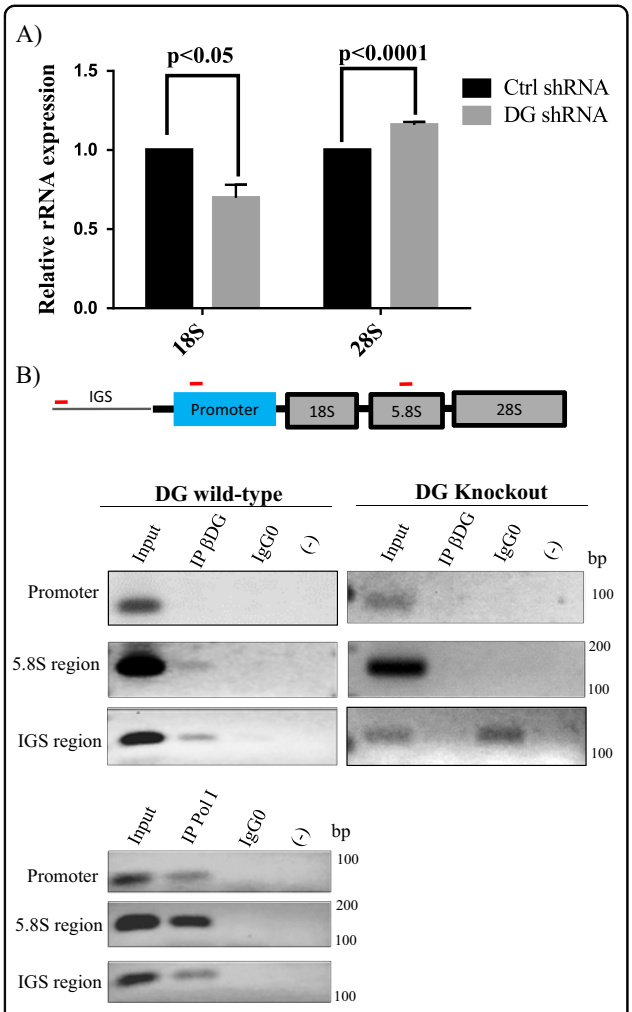

Fig. 5 β-DG binds to the rDNA gene regulatory region and knockdown of DG expression alters rRNA expression. a Total RNA was isolated from control shRNA and DG shRNA stably transfected cells and the expression of 18 S and 28 S pre-rRNAs was assessed by qRT-PCR using GAPDH as endogenous control. The expression levels obtained in control shRNA cells were set at 1 for comparison. Data correspond to the mean ± SEM from three independent experiments with duplicates; *p* values denoted significant differences (unpaired *t*-test). **b** Wild-type and DG knockout C2C12 cells were subjected to chromatin immunoprecipitation (ChIP) with antibody anti-β-DG (MANDAG), followed by PCR assays for the promoter, 5.8 S and IGS (intergenic sequence) regions of rDNA gene. ChIP assays using anti-PolI antibody were carried out in wildtype C2C12 cells as positive control. The drawing at the top shows the organization of the rDNA gene (bottom panel). IgG0 nonspecific antibodies, (-) mock reaction without antibodies

occupy all three regions of the rDNA (Fig. 5b). As expected, no PCR amplification was detected upon ChIP assays on DG knockout cells (right panel), which demonstrated the specificity of Mandag antibody for immunoprecipitating β-DG from chromatin. Overall these data suggest that β-DG may modulate rRNA transcript expression through its binding to the rDNA regulatory region.

Nucleolar stress-induced β-DG ICD cleavage correlates with impaired ribosome biogenesis

In an effort to understand the potential role of β-DG ICD in the nucleolus, we investigated whether β-DG ICD cleavage is induced by nucleolar stress. C2C12 cells were subjected to different kind of stresses, namely oxidative stress, acidosis, and UV irradiation, and effectiveness of treatments was monitored by p53 activation. Interestingly, the ratio of β-DG ICD/full-length β-DG was augmented in response to all treatments with concomitant decrease in UBF content, with H_2O_2 and UV being the most efficient inductors (Fig. 6a, b). As expected, H_2O_2-induced nucleolar stress resulted in nucleolar segregations, with a formation of UBF-stained nucleolar caps at the periphery of B23-stained nucleoli (Supplementary Figure 3), which elicited ultimately downregulation of 45 S rRNA expression (Fig. 6c) and abnormal ribosomal profiling characterized by decreased monosomes and polysome absorbance peaks (Fig. 6d). We hypothesized that augmented β-DG ICD levels could be reflected in a higher binding activity to the rDNA promoter; consistent with this idea, occupancy of the three rDNA regulatory regions by β-DG markedly increased after H_2O_2 treatment, as revealed by ChIP-qPCR assays (Fig. 6e).

Overexpression of β-DG ICD impairs ribosomal biogenesis by suppressing UBF function

To analyze directly the implication of β-DG ICD in ribosome biogenesis, we stably transfected C2C12 cells with a GFP-β-DG ICD vector, to mimic high levels of the cleavage fragment. GFP-β-DG ICD localization was restricted to the nucleus showing homogenous distribution throughout the nucleoplasm, with less intense staining in nucleoli (Fig. 7a). Remarkably, the significant number of GFP-β-DG ICD-transfected cells exhibited mislocalization of UBF foci to the cytoplasm, compared to GFP alone (50% and 20%, respectively), while the nucleolar distribution of B23 remained unaltered (Fig. 7a, bottom panel and right panel). Impaired nucleolar localization of UBF due to exogenous β-DG ICD expression was confirmed by transfecting FLAG-tagged β-DG ICD (Supplementary Figure 4, top rows). Furthermore, overexpression of GFP-β-DG ICD resulted in decreased levels of UBF with no effect on B23, compared to GFP alone (Fig. 7b and right panel). We have demonstrated previously that the phosphorylation of β-DG at Tyr890 is not only a signal for the proteolysis and internalization of dystroglycan[3,16,22] but also acts to target dystroglycan to the nucleus[10]. We considered therefore whether phosphorylation of β-DG ICD at the PPxY motif (Tyr^{890}) plays a role in UBF mislocalization. Thus, FLAG-β-DG ICD

Fig. 6 Nucleolar stress triggers β-DG ICD and disturbs rRNA expression and ribosome profile. a Lysates from control (ctrl, untreated) cells or cells induced to nucleolar stress response by H_2O_2 treatment, UV irradiation or acidosis (pH 6) (see Methods for details) were analyzed by western blotting using specific antibodies against β-DG, UBF, B23, p53, and α-tubulin. **b** Quantification of β-DG ICD/β-DG full-length ratio and UBF levels was carried out using α-tubulin as loading control. Results correspond to the mean ± SEM of three independent experiments with *p* values denoting significant differences (ordinary one-way ANOVA). **c** The 45 S rRNA precursor expression was assessed by qRT-PCR using GAPDH as endogenous control. The expression levels obtained in control cells were set at 1 for comparison. Data correspond to the mean ± SEM from three independent experiments with duplicates; *p* values denoted significant differences (unpaired *t*-test). **d** Ribosome profiling from control and H_2O_2-treated cells are shown. **e** Chromatin immunoprecipitation assays on control and H_2O_2-treated C2C12 cells were performed, with specific antibody against β-DG (Mandag), followed by SYBR green-based qPCR assays for the promoter, 5.8 S and IGS (intergenic sequence) regions of rDNA gene. Scheme of rDNA gene regulatory regions is shown at the top

variants that either mimic (Y890E) or block (Y890A) the Tyr^{890} phosphorylation were analyzed for UBF localization. Similar percentage of transfected cells showing UBF outside of the nucleus were observed between β-DG ICD FLAGY890A and β-DG ICD-FLAGY890E; thus, overexpression of β -DG ICD resulted in UBF mislocalization irrespective of a charged residue at residue 890 that mimics phosphorylation (Supplementary Figure 4). We hypothesized that decreased expression/mislocalization of UBF through β-DG ICD overexpression would ultimately impact rRNA expression. Consistent with this idea, an ~50% decrease in 45 S rRNA and 28 S but not 18 S was found in cells stably overexpressing β-DG ICD, compared with those expressing GFP alone (Fig. 8a). To ascertain whether β-DG ICD overexpression influences Pol I transcription, functional rRNA promoter reporter assays were carried out in β-DG ICD stably transfected cells, using a vector that expresses Firefly luciferase under the control of the mouse rRNA promoter and a vector that expresses Renilla luciferase to normalize transfection efficiency. Pol I promoter activity was found to decrease by 40% in GFP-β-DG ICD-transfected, compared with those with GFP alone (Fig. 8b). Because the rRNA content is a crucial point of regulation for ribosome biogenesis, we hypothesized that decreased 40 S and 60 S levels would impact the ribosome profile. Consistent with this notion, altered ribosome profiles devoid of the peaks corresponding to free 40 S and 60 S ribosomal subunits were observed in cells expressing β-DG ICD (Fig. 8c). Such impairment in rRNA expression and polysome profiling ultimately leads to defective proliferative capacity of β-DG ICD overexpressing cells, as shown by MTT-based proliferation assays (Fig. 8d). Collectively these data indicate that β-DG ICD acts as negative regulator of rRNA expression by affecting both the levels and transcriptional activity of UBF.

Discussion

β-DG is a key component of both PM and NE, acting as a platform for the proper anchorage of organelle-specific protein assemblies. At the PM β-DG modulates adhesion/signaling by connecting extracellular matrix proteins with the actin-based cytoskeleton[5,7], while in the nucleus β-DG interacts with the NE proteins emerin and lamins A/C and B1 to regulate nuclear structure and function[11,12]. This functional diversity could be wider than originally thought, due to the potential function of β-DG proteolytic fragments. Recent in vitro and in vivo evidence showed that β-DG undergoes two successive and possibly coordinate proteolytic cleavages that result in the liberation of the intracellular domain (ICD) into the cytosol; first matrix metalloproteinases, MMP-2 and MMP-9 cleave the extracellular domain of β-DG[23] and create a membrane-tethered intermediate that is subsequently processed by γ-secretase, a PM-embedded protease complex, to render a final cleavage product that approximates the entire ICD[21]. Except for cell density[21], other cellular stimuli inducing β-DG ICD release as well as the physiological consequences of such processing event are largely unknown. In this study we showed that β-DG ICD associates to nucleoli and its cleavage is promoted by the induction of a different kind of nucleolar stresses. We also ascribed for the first time a role for β-DG ICD in regulating rRNA transcription through negative regulation of the expression and transcriptional activity of UBF, in the context of the response to nucleolar stress.

We show herein that β-DG colocalizes and interacts with the key nucleolar proteins B23 and UBF, and, based on the converging redistribution of β-DG with B23, fibrillarin, or UBF in response to both actinomycin- and DRB-induced nucleoli disorganization, we hypothesized that β-DG participates in the functional plasticity of nucleoli. Interestingly, cell fractionation experiments revealed the presence of β-DG ICD but not β-DG full-length in the nucleolar fraction of C2C12 cells; however, GFP-based IP experiments revealed that both β-DG ICD and β-DG full-length are able to bind UBF. Because full-length β-DG is an NE protein associated with nuclear lamin and because the interaction of intranuclear filaments of lamins with nuclear compartments (including nucleoli) has been well established[24–26] it is possibly that IP of β-DG full-length pulled down a nuclear

INFORME DE LABORES 2019

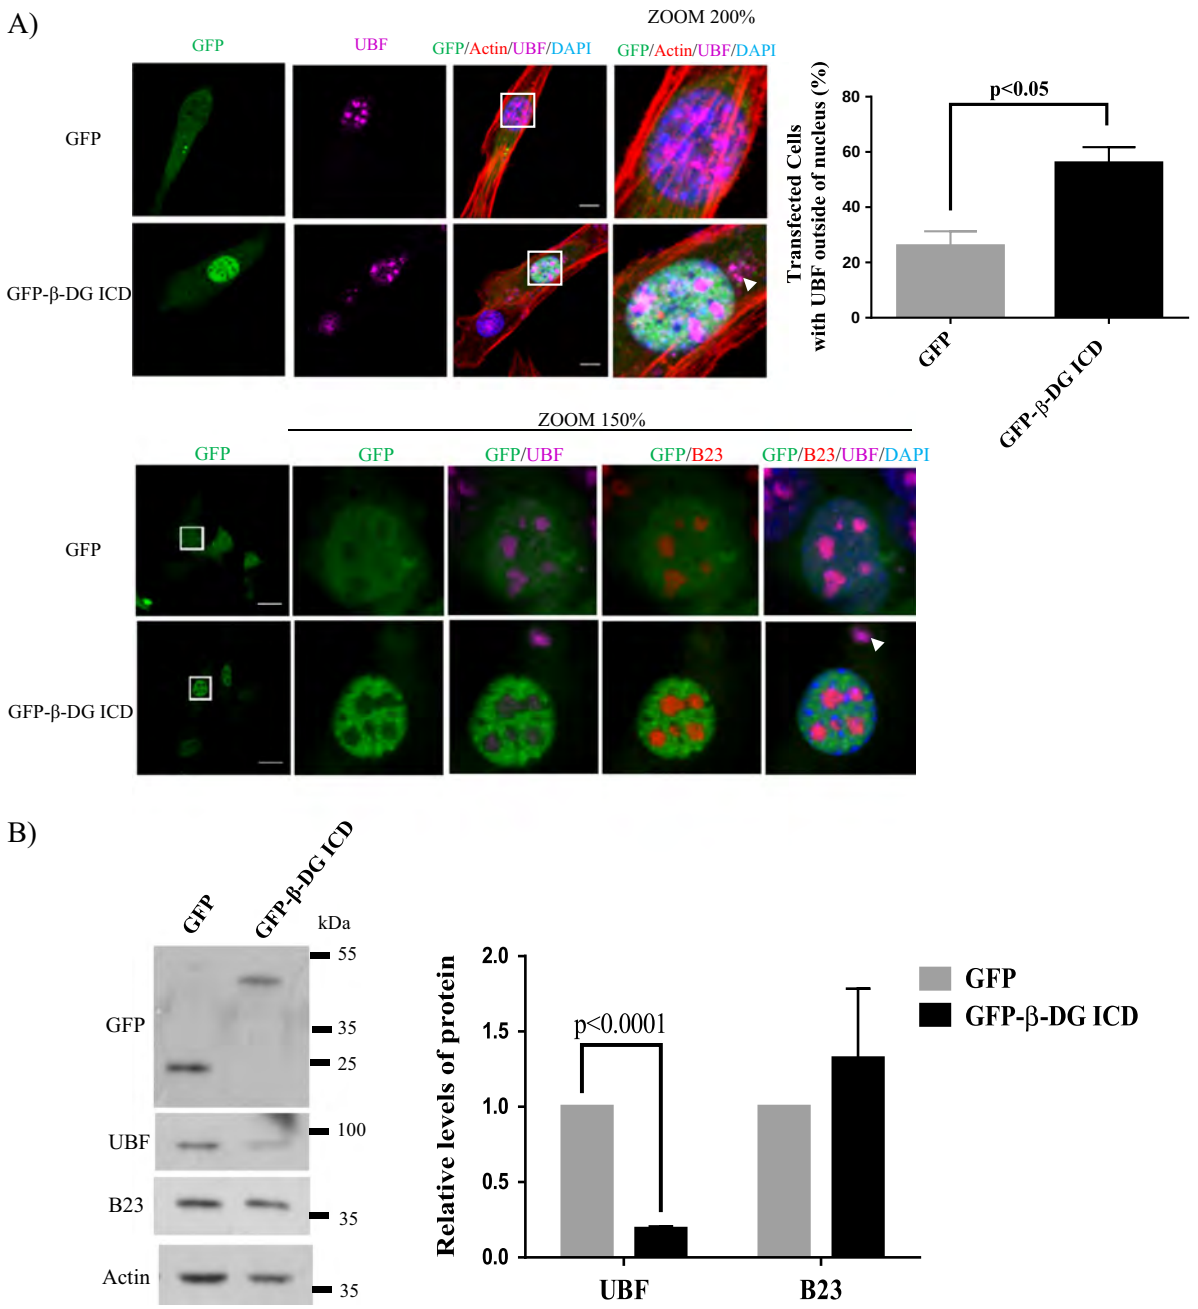

Fig. 7 Overexpression of β-DG ICD induces mislocalization and reduces UBF levels. a C2C12 cells transiently expressing GFP or GFG-β-DG ICD were immunolabeling for UBF at 24 h post-transfection. Cells were then fixed, stained with phalloidin and DAPI to visualize actin and nuclei, respectively, and subjected to CLSM analysis. In parallel experiments transfected cells were double immunostained for UBF and B23 and counterstained with DAPI to visualize nuclei prior to CLSM analysis (bottom panels). Scale bar = 10 µm. Mislocalized UBF is denoted by arrowheads. Quantification of cells transfected with GFP and GFP-β-DG ICD that showed UBF outside of the nucleus (right panel). Results correspond to the mean ± SEM of three independent experiments with *p* values denoting significant differences (unpaired *t*-test), *n* = 50 per experiment. **b** Lysates from GFP- or GFG-β-DG-ICD-transfected cells were analyzed by western blotting using specific antibodies against GFP, UBF, B23, and actin (loading control). *Right*: Data correspond to the mean ± SEM from three independent experiments, with *p* values indicating significant differences (unpaired *t*-test)

macromolecular complex containing NE (lamin B1) and nucleolar (UBF) proteins. The trafficking pathway underlying nucleolar targeting of β-DG ICD remains to be deciphered. Full-length β-DG is translocated to the nucleus through recognition of its NLS by importins α2/β1[9], therefore it is likely that β-DG ICD enters the nucleus by virtue of the NLS that is still present in the cleaved fragment, or alternatively by passive diffusion

INFORME DE LABORES 2019

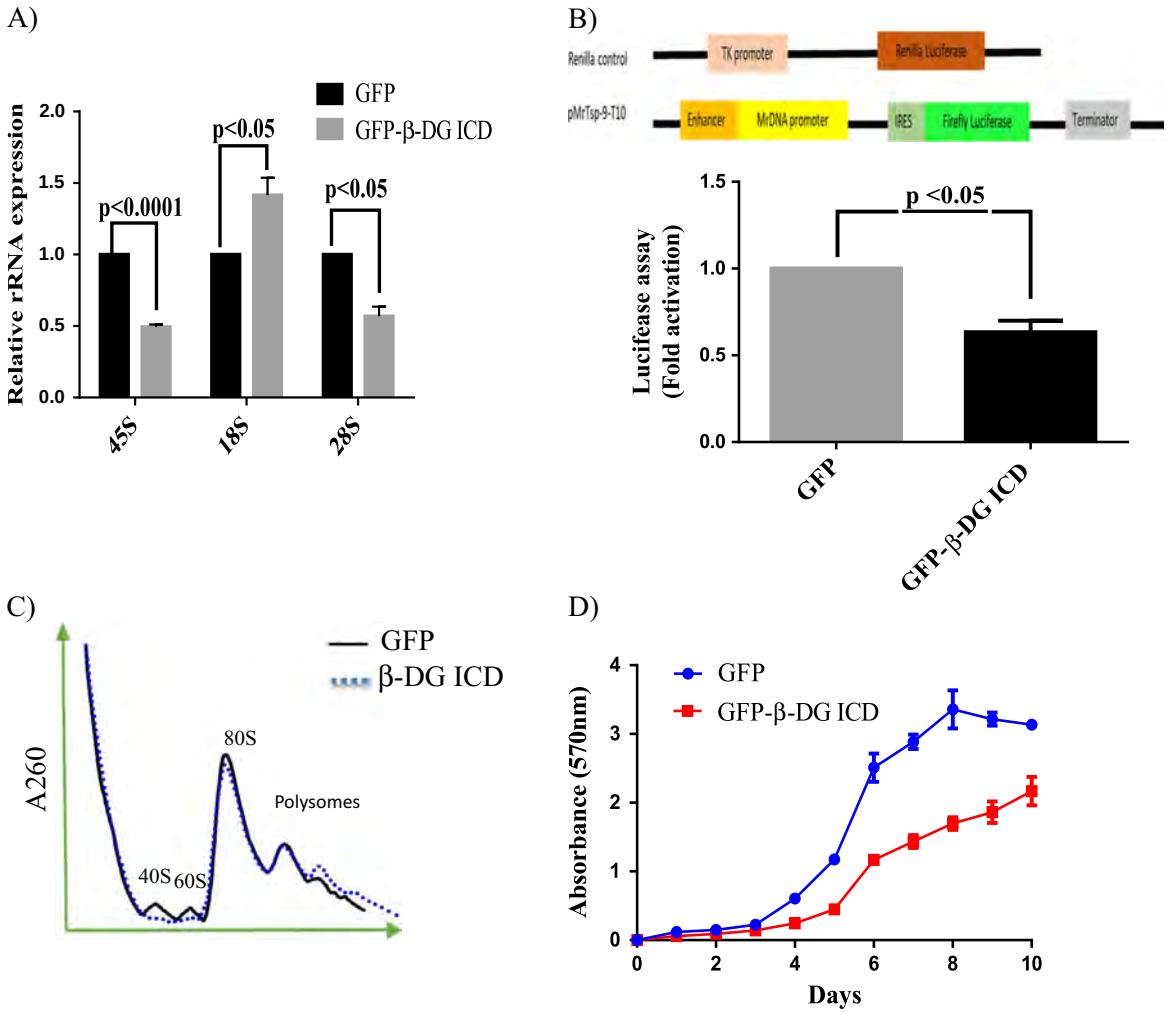

Fig. 8 Exogenous expression of β-DG ICD impairs ribosome biogenesis by affecting transcriptional activity of UBF. C2C12 cells were transfected to stably express GFP-β-DG ICD or GFP alone (empty vector). **a** The expression of 45 S, 18 S, and 28 S rRNAs was analyzed in the transfected cell cultures, using GAPDH as endogenous control. **b** Schematic representation of the mouse rDNA promoter construct (pMrTsp-9-T10) and *Renilla* luciferase control vector is shown at the top. Cell cultures stably expressing GFP-β-DG ICD or GFP alone were co-transfected with both luciferase reporter constructs and transcriptional activities were estimated after incubation for 48 h, as described in Methods. Control condition obtained in cells transfected with GFP alone was set at 1 for comparison. Data represent mean ± SEM of three independent experiments; *p* values denote a significant difference (unpaired *t*-test). **c** The ribosomal gradient profiles obtained from transfected cell cultures are shown. **d** Cell proliferation of the stably transfected cell cultures was monitored over a 10-day period using the MTT assay. Data represent mean ± SEM of three independent experiments

through the nuclear pore complex (NPC), because its molecular mass (<30 kDa) is clearly below the NPC permissive size[27]. No obvious nucleolar localization signal is found in β-DG ICD, thus, its nucleolar accumulation might be mediated by a retention mechanism via interaction with nucleolar components. Supporting this idea, β-DG ICD was found to interact with B23, a shuttle protein that transports cargos between the cytoplasm and the nucleolus and mediates nucleolar retention of other proteins[28]. Furthermore, binding of β-DG to the rDNA gene regulatory region (see below) could serve to anchor β-DG ICD to nucleoli too. Owing to the main contribution of nucleoli in ribosome biogenesis[16], we wondered whether β-DG is involved in this process. We provide here solid evidence supporting this hypothesis: first, β-DG interacts with UBF, an HMG box-containing protein that binds directly with rDNA and plays an important role in the recruitment of SL1 (selectivity factor 1) and Pol I to the rRNA promoter to constitute the Pol I preinitiation machinery complex[29]; second, ChIP assays with anti-β-DG antibody demonstrated β-DG recruitment to the rDNA 5.8 S and IGS regulatory regions; and third, DG silencing resulted in reduced UBF levels, decreased 18 S pre-rRNA expression but not 28 S pre-rRNA

INFORME DE LABORES 2019

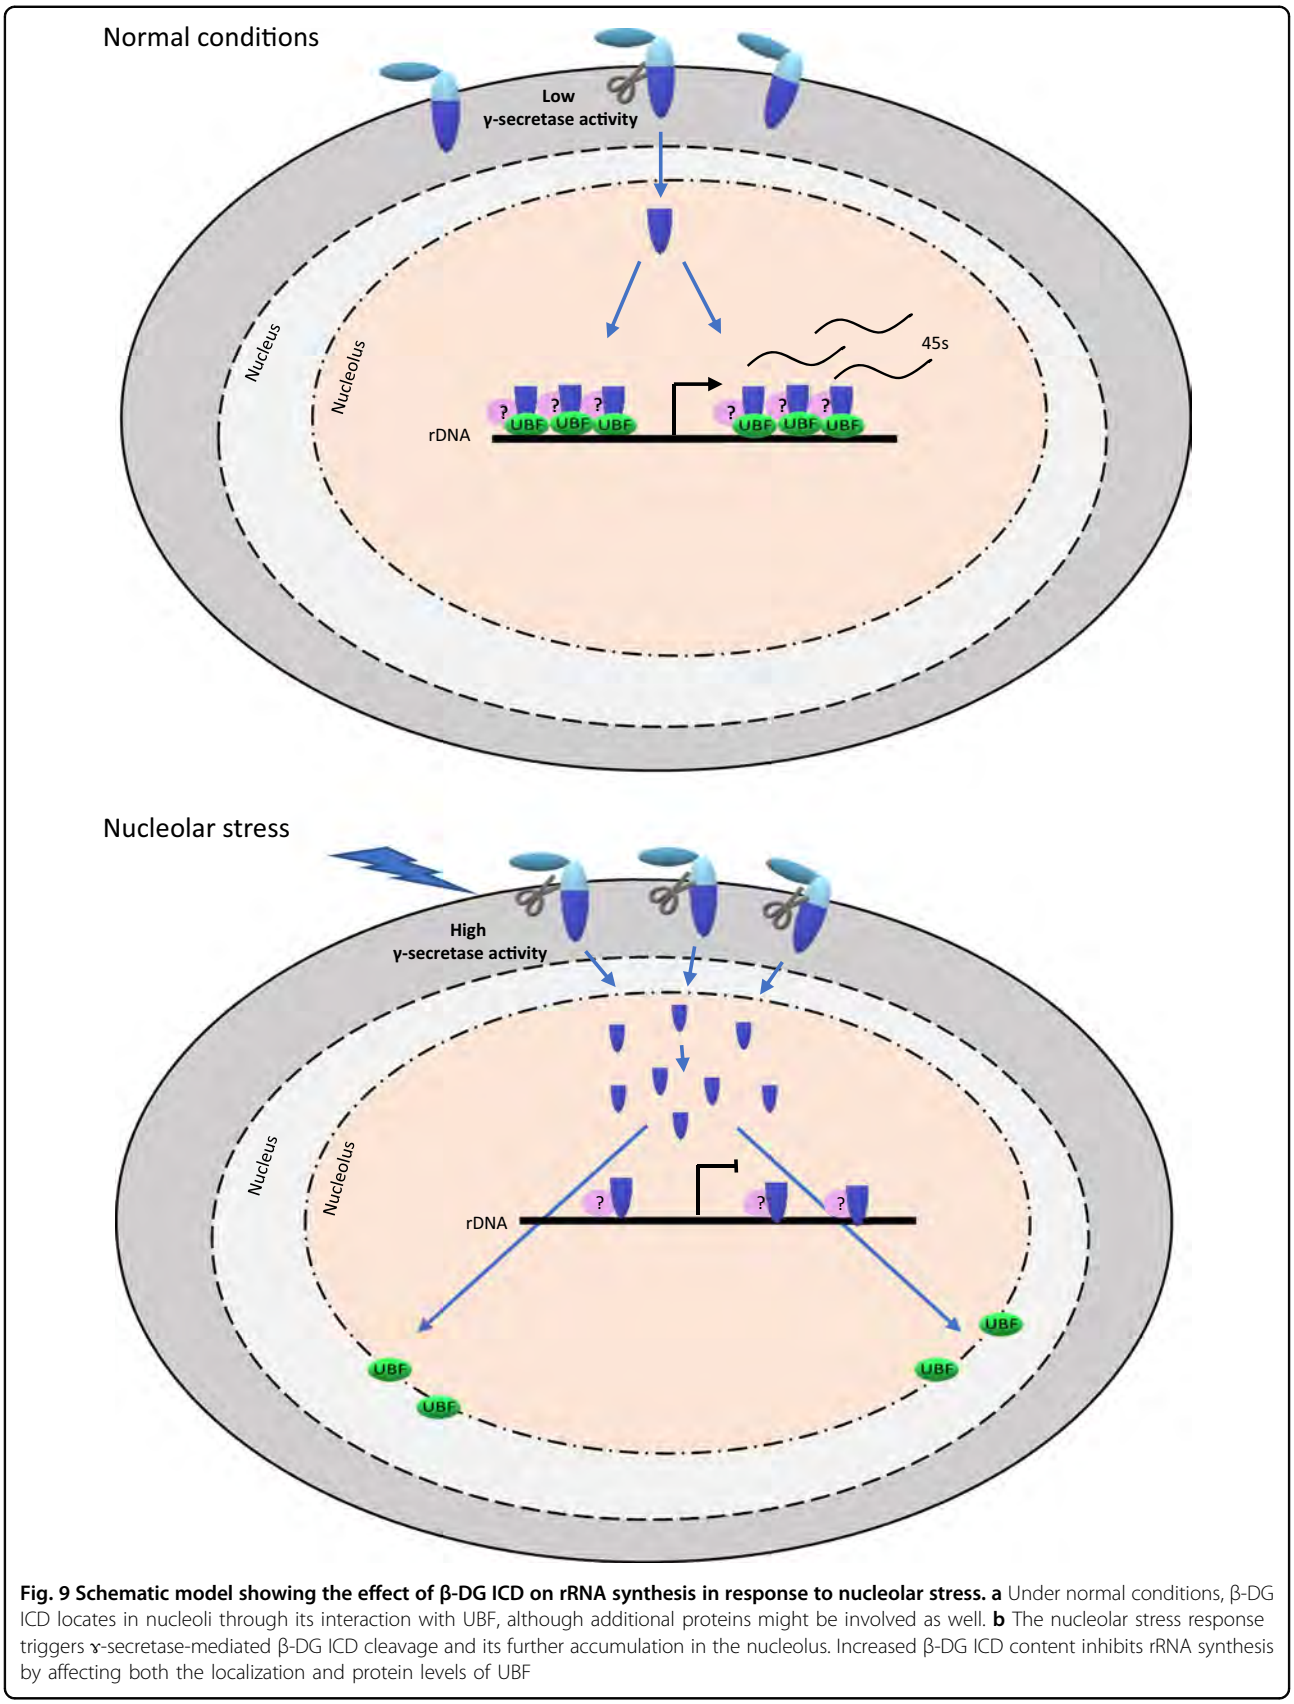

Fig. 9 Schematic model showing the effect of β-DG ICD on rRNA synthesis in response to nucleolar stress. a Under normal conditions, β-DG ICD locates in nucleoli through its interaction with UBF, although additional proteins might be involved as well. **b** The nucleolar stress response triggers ɤ-secretase-mediated β-DG ICD cleavage and its further accumulation in the nucleolus. Increased β-DG ICD content inhibits rRNA synthesis by affecting both the localization and protein levels of UBF

INFORME DE LABORES 2019

expression, and aberrant nucleolar morphology. Discordant expression between 28 S and 18 S rRNAs is intriguingly. Even though both 28 S rRNA and 18 S rRNA are originated from 45 S rRNA precursor, their processing/maturation pathways differ from each other, and each one is assisted by specific exo and endoribonucleasas[30]. Therefore, we argue that aside from its effect on rDNA basal transcription machinery (as shown here), β-DG ICD might modulate processing pathways of 18 S rRNA and 28 S rRNA differentially by indirect mechanisms. Additional experiments are needed to clear this issue.

The nucleolus is a central hub for orchestrating stress response, with downregulation of rRNA synthesis taking place as a part of ribosome biogenesis surveillance[31], furthermore, numerous proteins that functions are not generally ascribed to ribosome biogenesis are recruited to the nucleolus in response to environmental stimuli[32]. Therefore, we ascertained whether β-DG ICD cleavage is coupled to the response to nucleolar stress. Remarkably, triggers of β-DG ICD cleavage by Notch signaling activation occurred in response to different nucleolar stressor treatments, including oxidative stress, acidosis, and UV irradiation. Supporting a role for β-DG ICD in the response to nucleolar stress, β-DG ICD overexpression was sufficient to elicit several features of nucleolar stress, including mislocalization and decreased levels of UBF, repression of rRNA transcription, altered ribosome profile, and decreased cell proliferation.

The results raise the question of how β-DG ICD exerts a negative regulation on rDNA expression. β-DG lacks DNA-binding motifs or enzymatic activity and is considered as a scaffold protein, due to the presence of protein modules supporting interactions with diverse proteins (e.g. SH3, SH2, and WW domains)[5]. Therefore, we postulate that binding of β-DG ICD to UBF may lead to mislocalization and decreased levels of the latter protein, possibly by altering its stability, thereby interfering with the assembly of the Pol I initiation complex and the subsequent UBF-dependent activation of rDNA transcription (Fig. 9). Because the occupancy of rDNA regulatory regions by β-DG increased in response to nucleolar stress, it is also possible that β-DG ICD exerts its suppressive effect by displacing UBF from the Pol I transcription complex, which is consistent with mislocalization of UBF to the nucleolar periphery and cytoplasm that was observed in H_20_2-treated cells. Further ChIP assays to ascertain whether β-DG and UBF coexist or not in the rDNA promoter region under nucleolar stress conditions are needed to solve this question. Furthermore, since β-DG has multiple partners in the nucleus, the existence of an indirect mechanism by which β-DG ICD represses UBF activity cannot be ruled out. The implication of β-DG ICD in rDNA expression could be envisioned as an extension of the homeostatic role of β-DG, where induction of ICD cleavage and its further targeting to the nucleolus in response to environmental stress, like oxidative stress, acts as a protective response to inhibit rDNA transcription and further proliferation of damaged cells.

In summary, our data are compatible with the paradigm that β-DG ICD functions as a negative regulator of rRNA transcription by impeding the transcriptional activity of UBF, as a part of the nucleolar stress response mechanisms that are activated under physiologically relevant stress conditions. Thus, in addition to its roles as PM and NE signaling scaffold, β-DG should be regarded as a regulator of Pol I transcription in the nucleolus.

Materials and methods

Cell culturing and treatments

Mouse C2C12 myoblasts (ATCC® CRL-1772™) were grown as previously (Vásquez-Limeta, et al 2014). Generation of C2C12-derivative DG knockout cell lines with the CRISP/Cas9 system will be published elsewhere. For nucleoli disorganization treatments, cells were treated for 3 h with 0.01 μg/ml Act D (Sigma-Aldrich, St Louis, Missouri) or 25 μg/ml DRB (5,6 dichloro-1–d-ribofuranosylbenzimidazole; Sigma-Aldrich, St Louis, Missouri) or vehicle alone (DMSO), prior to confocal laser scanning microscopy (CLSM) analysis. The ɤ-secretase inhibitor N-(N-(3,5-difluorophenacetyl)-L-alanyl). S-phenylglycine t-butyl ester (DAPT; Sigma-Aldrich, St Louis, Missouri) was used at 10 μM for 24 h. For induction of the nucleolar stresses response, cells were cultured in DMEM supplemented with serum adjusted to pH 6, treated with 1.4 mM H_2O_2 (7722-84-1,Sigma-Aldrich) for 4 h or subjected to UV radiation using a pulse of 20 J/cm^2 each 24 h for 2 days. For nuclease digestion assays, cells grown on coverslips were treated with either 100 μg/ml protease-free RNase A in CSK buffer (10 mM Pipes pH 6.8, 100 mM NaCl, 30 mM sucrose, 3 mM $MgCl_2$, 1 mM EGTA, 0.5% (v/v) Triton X-100) for 40 min at 37 °C or with 200 μg/ml protease-free DNase I in PBS with 5 mM $MgCl_2$ for 1 h at 37 °C, then the cells were fixed with PFA 4% and immunolabeled using primary antibodies and the corresponding fluorochrome-conjugated secondary antibodies. Negative control experiments were carried out by incubating cells only with CSK buffer (RNase) or PBS with 5 mM $MgCl_2$ (DNase) prior to fixation.

Plasmids and transfection

The expression vectors Flag-β-DG ICD WT, Flag-β-DG ICDY890E, and Flag-β-DG ICDY890A were generated by PCR amplification using DGWT-DG, DGY890E-GFP, and DGY890A-GFP plasmids as template, respectively[10]. The cDNA sequence encoding the intracellular domain of β-DG (ICD, amino acids 774–895) was amplified using an

INFORME DE LABORES 2019

M-MLV reverse transcriptase coupled to a high-fidelity polymerase (*Pfu* turbo; Strategene) and primers containing Hind III and EcoRI restriction sites. Forward primer was 5′-CCTAAGCTTTATCGCAAGAAGAGGAAGGGC-3′ and the respective reverse primers were 5′-CTGAATTCTTAAGGGGGAACATACGGAGGG-3′ (ICD WT), 5′-CTGGAATCCTTAAGGGGGAAC**CTC**CGGAGGG-3′ (ICD Y890E mutation), and 5′-CTGAATTCTTAAGGGGGAAC**TGC**CGGAGGG-3′ (ICD Y890A mutation). PCR products were double digested with Hind III and EcoRI and cloned into the Hind III-EcoRI digested pFlag-CMV-10 vector. The integrity of the constructs was confirmed by DNA sequencing. Transfection was performed following supplier's recommendations. Briefly, cells seeded onto glass coverslips were incubated overnight and then transfected with 3 µg of the corresponding vector premixed with 3 µl of Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA). Transiently transfected cells were analyzed at 24 h post-transfection. When indicated, cells were stably transfected by culturing them for 12 days in the presence of 2 µg/ml puromycin (Invitrogen) or for 5 days in the presence of 800 µg/ml gentamicin (G418), prior to being used for further experiments. For knockdown experiments, cells were stably transfected with psiMH1 vector expressing a small interfering RNA (RNAi) specific for mouse DAG1 gene or a scrambled RNAi, as negative control (GeneCopoeia, Inc., Rockville, MD). For overexpression analysis, cells were stably transfected with GFP constructions as previously reported[9].

Antibodies

The following anti-β-DG primary antibodies were used: rabbit polyclonal antibodies G5 (Royuela et al, 2001) and Dystroglycan pTyr892 (Ilsley et al, 2002); goat polyclonal antibody C20 (Santa Cruz Biotechnology, CA), and mouse monoclonal antibodies MANDAG2[33] and 7D11 (Santa Cruz). Rabbit polyclonal antibodies anti-B23 (C19-R), anti-Nup62 (H-122), anti-calnexin (H70), anti-fibrillarin (Ab5821), anti-GFP (sc8334) and mouse monoclonal antibodies anti-UBF (F9), anti-B23 (NPM1-FC-61991) (anti-RNA polymerase I (sc-46699), anti-lamin B1 (Ab16048), anti-and anti-RPA(sc-46699), and α-Tubulin (sc-32293) were purchased from Santa Cruz Biotechnology, CA, USA. Rabbit polyclonal anti-Flag (2368) and rabbit monoclonal anti-Notch1 (4147) antibodies were acquired from cell signaling, while mouse monoclonal anti-actin antibody was a gift from Dr. Manuel Hernández (CINVESTAV, Mexico City).

Immunofluorescence and confocal microscopy analysis

Cells grown on coverslips were fixed with 4% paraformaldehyde for 10 min in PBS, permeabilized with 0.2% Triton X-100-PBS, blocked with 0.5% fetal bovine serum and 3% bovine serum albumin (BSA) in PBS and incubated overnight at 4 °C with the appropriate primary antibodies. The following day, cells were washed with 0.2% Triton X-100-PBS for 5 min and then with PBS alone three times, prior to be incubated for 1 h at room temperature with the appropriate fluorochrome-conjugated secondary antibody. For double immunolabeled samples, this was followed by overnight incubation at 4 °C with corresponding primary antibodies and the next day, cells were incubated with secondary fluorochrome-conjugated antibodies. Where indicated F-actin was labeled using TRITC-conjugated Phalloidin (Sigma-Aldrich St. Louis, Mo. USA) diluted 1:500 in PBS for 10 min at room temperature. For nuclease digestion assays, cells grown on coverslips were treated with either 100 µg/ml protease-free RNase A in CSK buffer (10 mM Pipes pH 6.8, 100 mM NaCl, 30 mM sucrose, 3 mM $MgCl_2$, 1 mM EGTA, 0.5% (v/v) Triton X-100) for 40 min at 37 °C or with 200 µg/ml protease-free DNase I in PBS with 5 mM MgCl2 for 1 h at 37 °C. Cells were then immunolabeled using primary antibodies and the corresponding fluorochrome-conjugated secondary antibodies. Finally, coverslip preparations were incubated for 20 min at room temperature with 0.2 µg/ml diamidino-2-phenylindole (DAPI; Sigma-Aldrich) for nuclei visualization, mounted on microscope slides with VectaShield (Vector Laboratories Inc. Burlingame, CA, USA) and further analyzed by CLSM (TCP-SP5, Leica Microsystems, Heidelberg, Germany) using a Plan Neo Fluor 63 × (NA = 1.4) oil-immersion objective. Analyses of digitized images were carried out using ImageJ 1.62 software. The nucleolar area (μm^2) of 600 nucleoli was analyzed in maxima projection using 3D objects counter and the data were analyzed using Prism6 software. Manders overlap coefficients were calculated for double labeling inmunofluorescences, using red (Alexa 594 nm) and green (FITC 488 nm) channels and the ImageJ plugin JACoB. A line intensity scan analysis was performed by ROI manager Multiplot.

Western blotting

Cell lysates were electrophoresed on 10% SDS-polyacrylamide gels and transferred onto nitrocellulose membranes (Hybond-Nb, Amersham Pharmacia, GE Healthcare, Bukinghamshire, UK). Membranes were blocked in TBST (100 mM Tris-HCl pH 8.0, 150 mM NaCl, 0.5 % (v/v) Tween-20) with low fat-dried milk and then incubated overnight at 4 °C with the appropriate primary antibodies. The specific protein signal was developed using the corresponding secondary antibodies and enhanced chemiluminescence western blotting detection system (ECL™; Amersham Pharmacia, GE Healthcare), according to the manufacturer's instructions.

Cell fractionation

Total cell extracts were obtained with lysis Buffer (10 mM Tris-HCl pH 8, 30 mM NaCl, 0.2% Triton X-100, 4

INFORME DE LABORES 2019

mM Na_3O_4V, 50 mM NaF, 20 mM Na_2MoO_4, 1 mM PMSF, 1X complete protease inhibitor) sonicated three times at 3.5 µm with 15 s bursts and analyzed by western blotting. Purification of the cytosolic, nuclear, and nucleolar fractions was performed as previously reported[34]. A total amount of fifteen 100 mm dishes grown to 90% confluence were used; cells were washed twice with 1 ml of ice-cold PBS and collected by centrifugation at 15,000 rpm for 15 min at 4 °C. The pellet was resuspended in 1 ml of buffer TM (10 mM Tris-HCl pH 8, 2 mM $MgCl_2$, 25 mM NaF, 10 mM Na_2MoO_4, 2 mM Na_3VO_4, 1 mM PMSF), supplemented with 1× complete protease inhibitor mixture (Roche Applied Science, Indianapolis, USA), and incubated on ice for 10 min. Then, 2% Triton X-100-PBS was added, and the homogenate incubated for 10 min on ice, transferred to a glass Dounce homogenizer, stroked 30 times with B pestle, and centrifuged at 5,000 rpm for 15 min at 4 °C. The supernatant was recovered as the cytosolic fraction and the nuclear pellet was resuspended in 1 ml of buffer I (0.32 M Sucrose, 3 mM $CaCl_2$, 2 mM $Mg(CH_3COO)_2$, 0.1 mM EDTA, 10 mM Tris-HCl pH 8, 1 mM DTT, 0.5 mM PMSF, 0.5% (v/v) NP40) and 1 ml of Sucrose buffer II (2 M Sucrose, 5 mM $Mg(CH_3COO)_2$, 0.1 mM EDTA, 10 mM Tris-HCl pH 8.0, 1 mM DTT, 0.5 mM PMSF), and further purified by sucrose gradient centrifugation at 16,000 rpm for 1 h at 4 °C. The pellet was resuspended in 600 µl of buffer III (0.34 M Sucrose, 1 mM $MgCl_2$, 0.1 mM EDTA, 10 mM Tris-HCl pH 8.0, 1 mM DTT, 0.5 mM PMSF) and aliquots collected for extraction of nuclear and nucleolar proteins. For nuclear proteins, the aliquot was centrifuged at 1,000 rpm for 5 min at 4 °C and the pellet resuspended in 200 µl of lysis buffer (50 mM Tris-HCl pH 8.0, 150 mM NaCl, 1 mM PMSF, 1% (v/v) Triton X-100), supplemented with protease inhibitor cocktail and phosphatase inhibitors, sonicated 3 times at 4µm with 15 s bursts and 4 min on ice between intervals, and then pre-cleared at 13,000 rpm for 2 min at 4 °C. For purification of nucleoli, the remaining 350 µl aliquot was sonicated 5 times at 5 µm with 30 s bursts and analyzed under a light microscope to ensure nucleoli integrity, prior to purification by centrifugation at 3,000 g for 20 min at 4 °C through a sucrose gradient, using buffer III and four volumes of Sucrose buffer IV (0.88 M Sucrose, 0.1 mM EDTA, 10 mM Tris-HCl pH 8.0, 1 mM DTT, 0.5 mM PMSF). Finally, the pellet was washed in 500 µl of buffer III and centrifuged at 2,000 g for 2 min at 4 °C, to save the supernatant as the nucleolar fraction[34].

Immunoprecipitation

Recombinant protein G-agarose beads (10 µl per sample; Invitrogen, Carlsbab, CA, USA) were equilibrated by gently agitation in lysis buffer (50 mM Tris-HCl pH 8, 150 mM NaCl, 1% Triton X-100, 2 mM Na_3VO_4, 25 mM NaF, 10 mM Na_2MoO_4, 1 mM PMSF, and 1× complete protease inhibitor mixture). We quantified 500 ug of protein and the lysates were pre-cleared with equilibrated beads for 2 h at 4 °C, the beads were removed by centrifugation at 3,500 rpm for 5 min and the pre-cleared extracts incubated overnight at 4 °C with the appropriate antibody. Incubations with an irrelevant IgG antibody were carried out in parallel. Thereafter, equilibrated protein G-agarose beads blocked previously with 4% BSA were added to the lysates and incubated overnight at 4 °C. Immune complexes were collected by centrifugation at 3,500 rpm for 5 min, washed twice for 10 min with 500 µl of washing buffer (50 mM Tris-HCl, 150 mM NaCl, 5 mM EDTA, 1% Tritón X-100, 1X complete protease inhibitor, 1 mM PMSF). Bound proteins were eluted from beads by boiling in sample buffer (50 mM Tris-HCl pH 6.8, 2% (w/v) SDS, 10% (v/v) glycerol, 0.1% (v/v) 2-mercaptoethanol, 0.001% bromophenol blue), prior to being subjected to western blot analysis. C2C12 cell lysates expressing GFP-tagged proteins were subjected to IP using the GFP-Trap® system (Chromotek, Germany), according to the manufacturer's instructions.

Quantitative reverse PCR (RT-qPCR)

For analysis of rRNA transcripts, total RNA was extracted using Direct-zol ™ RNA Miniprep Kit (Zymo Research, Irvine, CA, USA), according to the manufacturer's instructions. And further analyzed by qRT-PCR with specific primers amplifying 45 S pre-rRNA (forward, 5′-GTGTCCAAGTGTTCATGCCA; reverse, 5′-CGATCTAAGAGTGAGCAACGAC), 18 S rRNA (forward, 5′-TTCCGACCATAAACGATGCC; reverse, 5′-GCTCCACCAACTAAGAACGG), 28 S rRNA (forward, 5′-GATGGTGAACTATGCTTGGG; reverse, 5′-GAATAGGTTGAGATCGTTTCGG), and GAPDH mRNA (forward, 5′-CTTGGGCTACACTGAGGACC; reverse, 5′-CTGTTGCTGTAGCCGTATTC). For analysis of *DAG1* mRNA expression, the following primers were used: forward, 5′-GAGATCATCAAGGTGTCTGCA and reverse, 5′-GTGGCTCATTGTGGTCTTCAG. RT-qPCR reactions were carried out in the StepOneplus System (Life technologies), using KAPA SYBR® FAST One-Step qRT-PCR Master Mix (2 ×) Kit, and further analyzed with the StepOne Software v2.3. The data were analyzed by comparative method $2^{-\Delta\Delta CT}$.

RNA pol I reporter assays

C2C12 cells stably expressing GFP-ICD-βDG or GFP alone were co-transfected with both the Renilla Luciferase vector (transcribed by RNA polymerase II) as a control to normalize for differences in transfection efficiency and with the firefly luciferase RNA polymerase I reporter vector (pMrTsp-9-T10). The two vectors were kindly donated by Gernot Längst Lab., Regensburg University,

INFORME DE LABORES 2019

Germany. After 48 h, the luciferase activity was measured using Dual Luciferase Assay kit (Promega). The firefly luciferase counts of the RNA polymerase I reporter were divided by the Renilla luciferase counts and compared to GFP control transfections.

Cell proliferation assays

C2C12 cells stably expressing GFP-ICD-βDG or GFP alone were harvested and plated in triplicate onto 12 wells microplates at 1×10^3 cells/mL confluence. Proliferation was measured for 13 days using the MTT (3-(4,5-dimethylthiazole)− 2–5-diphenyl tetrazolium bromide) commercial kit (Sigma-Aldrich), following the manufacturer's instructions.

Chromatin immunoprecipitation assays

C2C12 cells were incubated with 1% formaldehyde in PBS for 10 min at room temperature. Cross-link reaction was stopped by adding glycine to a final concentration of 125 mM. Cells were washed and harvested with cold PBS. After centrifugation at 1500 g, the pellet was resuspended in sonication buffer (50 mM Hepes pH 7.9, 140 mM NaCl, 1 mM EDTA, 1% Triton X-100, 0.1% sodium deoxycholate, 0.1% SDS and protease inhibitors). Soluble and sheared chromatin were obtained by applying five cycles of sonication on ice at 10% of amplitude for 20 s (Q55 sonicator, Qsonica) and recovered by centrifugation. Soluble chromatin was pre-clarified by mixing with 50 µl of recombinant protein G-agarose beads (rPGA Invitrogen) and incubated with shaking for 1 h at 4 °C. The mix was centrifuged at 3,000 × g for 1 min to remove rPGA. Twenty five micrograms of pre-clarified chromatin diluted 1:10 in sonication buffer were mixed with 7.8 µg of mouse purified serum anti-β-dystroglycan or 7.8 µg of mouse IgG (irrelevant control). Finally 25 µl of rPGA were added to each sample and incubate with shaking overnight at 4 °C. Immunoprecipitated DNA-protein complexes were extensively and sequentially washed with sonication buffer, wash buffer A (50 mM Hepes pH 7.9, 500 mM NaCl, 1 mM EDTA, 1% Triton X-100, 0.1% sodium deoxycholate, 0.1% SDS), wash buffer B (20 mM Tris-Cl pH 8, 1 mM EDTA, 250 mM LiCl, 0.5% NP40, 0.5% deoxycholate), and TE buffer. Finally, the pellet was incubated with shaking for 10 min at 65 °C in elution buffer (50 mM Tris-Cl pH 8, 1 mM EDTA, 1% SDS, 50 mM $NaHCO_3$). Supernatant was recovered by centrifugation and the cross-link reversion was carried out by adding RNAase A and Proteinase K to each sample and incubating with shaking for 4 h at 65 °C. DNA was recovered by phenol–chloroform extraction and ethanol precipitation. Twenty nanograms of DNA was used to perform quantitative PCR (qPCR), using SYBR green and rDNA-specific primers as previously reported[35,36].

Ribosomal profile analysis

Cells grown at 80–90% confluency were harvested, washed with PBS with 100 µg/mL cycloheximide and centrifuged at 5,000 rpm for 5 min at 4 °C, prior to suspension in 200 µl of lysis buffer containing 100 µg/mL cycloheximide and 1× complete protease inhibitor mixture. Thereafter cells were centrifuged for 10 min at 10,000 rpm and the supernatant was layered on top of a 15–50% sucrose gradient to be centrifuged at 25,000 rpm for 5:30 h at 4 °C in a Beckman SW28Ti rotor. All gradients were scanned at 260 nm from the top with an ISCO gradient collector. Collected fractions were precipitated with ethanol and centrifuged at 15,000 rpm for 30 min to obtain ribosomal particles.

Abstract

The estrous cycle is an iterative change in the anatomy, endocrinology, physiology, and behavior to provide maximum fecundity. Ovarian steroid production involves gonadotropin-induced $[Ca^{2+}]_i$ raises due in part to voltage-gated Ca^{2+} channels (VGCCs) whose identity and tissue distribution *in situ* is largely unknown. Using fluorescence Ca^{2+} imaging and confocal microscopy, we recorded both spontaneous and depolarization-induced Ca^{2+} signals in living mouse ovarian slices. They were most prominent in theca cells (TCs) and oocytes. The presence of Ca^{2+} channel subunits Ca_V 1.2, Ca_V 1.3, Ca_V 2.1, Ca_V 2.2, and Ca_V 3 was examined with immunofluorescence of ovarian sections. Ca_V 1.2 and Ca_V 1.3 (L-type Ca^{2+} channels) are present in the stroma, granulosa cells (GCs), and corpora lutea (CL). Intriguingly subunits that are characteristic of nerve cells are also expressed: P/Q-type (Ca_V 2.1; α1A) in the stroma and CL cells and N-type (Ca_V 2.2; α1B) in perifollicular smooth muscle cells. The expression of α1 subunits fluctuates along the estrous cycle: in metestrus-diestrus (the quiescent stage of the cycle), CL and GCs are similarly stained, while in proestrus (stage of maximal ovarian stimulation) CL staining increases relatively to GCs. Also in proestrus, Ca_V 3 Ca^{2+} channel subunits are expressed more in CL compared to GC suggesting a more significant role of Ca^{2+} channels. In estrus, Ca_V 3 subunits from mesenchymal and interfollicular stromal cells

become intensely stained. Our study represents an important step in understanding the role of VGCCs in ovarian physiology and possibly in ovarian cancer and other reproductive pathologies.

Summary Sentence

Calcium signaling and the expression of voltage-gated Ca^{2+} channels in the ovary is heterogeneous and varies considerably along the estrous cycle.

Key words: estrous cycle, follicle, granulosa cells, ion channels, calcium signaling, ovary, ovulatory cycle, follicular development, immunofluorescence.

Introduction

Ion channels perform a diversity of important functions in mammalian cells. The ovary is not an exception. However, a detailed understanding of the molecular identity, cellular distribution, and functional role of the majority of ovarian ion channels is still absent. Such understanding would greatly improve our comprehension of the role of ion channels in ovarian physiology and physiopathology. Moreover, ion channels are emerging as important and specific targets of novel therapeutic approaches. A better knowledge of their role in ovarian function could allow the development of new treatments for fertility control and ovarian diseases. Ovarian theca and granulosa cells (GCs) are the main steroid-producing cells in the ovary. Along with the oocyte, they coordinate folliculogenesis, steroidogenesis, and ovulation [1]. TCs form a sheet of elongated endocrine cells approximately 3–5 cell layers thick immediately adjacent to the basal lamina known as the theca interna. The role of ion channels subtypes in ovarian function is incomplete and fragmentary. To this date GCs are the only ovarian cell type (besides the oocyte itself) studied in some detail with electrophysiological and molecular biology techniques [2, 3]. This is probably due to the fact that GCs escort the oocytes after ovulation and are easily obtained as a pure, uniform cell population for in vitro experiments. Nonetheless, these GCs originate from mature follicles and are at the final stage of their development, and they lack responsiveness to follicle-stimulating hormone (FSH) and no longer produce estrogen, but progesterone in response to stimulation with luteinizing hormone (LH) and human Chorionic Gonadotropin (hCG). Therefore, information on ion channels expression and function collected from mature GCs cells is likely to be incomplete.

Ion channels expressed in ovarian cells

Voltage-dependent and independent K^+ channels have been characterized molecularly, electrophysiologically, and pharmacologically in porcine GCs [4]. There is no doubt that ovarian K^+ channels are functionally relevant, since their antagonists disrupt several GCs functions, including steroid production [5, 6]. Several types of K^+ channels have also been identified in human GCs from in vitro fertilization patients, including the three types of Ca^{2+}-activated K^+ channels; IK, SK, and BK(Ca) [7, 8], and the ATP-sensitive potassium channel, K(ATP), which couples metabolic state and membrane potential. Glibenclamide, a K(ATP) channel blocker, depolarizes GCs and inhibits hCG-induced progesterone production [9].

The presence of voltage-gated tetrodotoxin (TTX)-sensitive Na^+ channels (Nav 1.7) has also been demonstrated in human GCs, where its functional role is subject of some debate [10]: it has been reported that veratridine (an Na^+ channel opener) reduces progesterone production and triggers the presence of secondary lysosomes, an autophagocytic process involved in the regression of the corpus luteum [2]. Conversely, TTX (a specific Na^+ channel blocker) does not seem to affect the GCs phenotype. Several Cl^- currents, both voltage-dependent and voltage-independent, have been recorded in chicken GCs, where they contribute to the negative resting membrane potential essential for action potential generation [11]. Expression of Cl^- currents has not been reported yet in mammalian GCs. Finally, two types of voltage-gated Ca^{2+} channels (VGCCs; T-type: low voltage activated [LVA] and L-type: high voltage activated [HVA]) have been described in porcine, chicken, and human GCs (see below) [11–17].

Data collected from over 30 years of research support the notion that $[Ca^{2+}]_i$ elevations, either from intracellular or extracellular sources, participate in the stimulation by gonadotropins of ovarian follicle steroid production, and several of these reports suggest a role of VGCCs in these phenomena [18]. Nonetheless, a comprehensive assessment about the identity and tissue distribution of VGCCs the ovary *in situ* is still lacking. Also, it is not known if Ca^{2+} channel expression and/or $[Ca^{2+}]_i$ signaling undergoes variations along the estrous cycle.

Ca^{2+} imaging experiments reported here for the first time revealed patterns of spontaneous and depolarization-induced Ca^{2+} signals in living ovarian slices in vitro. The information obtained with the Ca^{2+} indicator fluo-4 and confocal fluorescence microscopy suggests the participation of VGCCs in TCs. Spontaneous oocyte Ca^{2+} signals were also recorded. The results from these physiological experiments underscore the importance of understanding the expression of VGCCs in ovarian tissue. Immunofluorescence from ovarian frozen sections unveiled the diverse expression patterns of specific HVA and LVA Ca^{2+} channel subtypes at different stages of the estrous cycle. The information reported here is relevant to the understanding of Ca^{2+} signaling in ovary cells *in situ* and its regulation by gonadotropins. Also, it is of great interest in physiopathology, since increasing evidence demonstrates that the disruption of Ca^{2+} homeostasis underlies certain ovarian malignant phenotypes and ovarian reproductive pathologies.

Materials and methods

Animals

Female CD1 mice, 8 weeks of age, were used. They were maintained under controlled conditions of light and temperature (12 h light, 12 h dark), with free access to food and water. All animal studies were performed in accordance with the SSR's specific guidelines and standards and under the supervision of an Institutional Committee for the Use of and Care of Laboratory Animals (CICUAL Protocol # AHC115 (46)-17) and the Official Mexican Guide from the Secretary of Agriculture (SAGARPA NOM-062-Z00–1999). Mice were maintained in the animal facility and fed ad libitum. The stage of the estrous cycle was determined at the same time of day (10:00) for 8 to 10 consecutive days through vaginal smears [19]. Only mice that showed two consecutive estrous cycles of the same duration were selected. Animals were sacrificed at 12 o'clock on the expected day of metestrus-diestrus, proestrus, or estrus.

INFORME DE LABORES 2019

Preparation of acute ovarian slices

After decapitation under CO_2 anesthesia, the ovaries were rapidly removed and then carefully dissected, cleaned, and embedded in 3.0% low-melting point agarose (Invitrogen Catlab, CA) dissolved in Krebs–Ringer Bicarbonate buffer (KRB) at 37°C containing (125 mM NaCl, 2.5 mM KCl, 2 mM $CaCl_2$, 1 mM $MgCl_2$, 1.25 mM NaH_2PO_4, 26 mM $NaHCO_3$, and 12 mM glucose, gassed with 5% CO_2 and 95% O_2 to pH ~7.4). The agarose with embedded ovaries was hardened by immersion in ice-cold physiological solution, and the agar block was glued with cyanoacrylate onto the plate of a microtome. The slicing chamber was filled with physiological solution at 3°C, and transverse slices 150 μm in thickness were prepared using a vibrating blade microtome (Leica Microsystems VT 1000S GmbH). Freshly cut slices were transferred to an incubation beaker containing physiological solution at room temperature and continuously gassed (5% CO_2 and 95% O_2). Slices remained viable for up to 6 h after preparation.

Intracellular Ca^{2+} imaging of living ovarian slices

$[Ca^{2+}]$i changes were determined as previously described [31]. Briefly, mouse ovarian sections were incubated with 10 μM of the cell-permeable fluorescent Ca^{2+} indicator fluo-4 AM (Molecular Probes, Eugene, OR) for 35 min at room temperature in KRB. Slices were washed twice and placed in the bottom of a plexiglass recording chamber attached to the stage of an upright microscope (Nikon Eclipse 80i; Nikon Corp., Tokyo, Japan) and continuously superfused (2 ml/min) with KRB by gravity-fed perfusion. Fluo-4 was excited at 488 nm with monochromatic light from an argon laser (Laser Physics, Reliant 100 s488, West Jordan, UT), coupled to a Yokogawa spin-disk confocal scan head (CSU10B, Yokogawa Electronic Co., Tokyo, Japan and Solamere Technology Group, Salt Lake City). Excitation light was band passed to 488 nm with a filter cube placed in the light path, and emitted fluorescence was band passed (510 nm) before its reflection into the camera port. Fluorescence images were acquired with a water-immersion, Nikon objective (20x, 0.5 NA), and a cooled digital CCD camera (Andor Technology iXon 897, Oxford Instruments, High Wycombe, UK) controlled by the iQ software (Andor iQ version 1.10.2). Fluorescence images were acquired at 10 ms exposure and 500 ms intervals. All Ca^{2+} imaging experiments were performed at room temperature (22–24°C). Fluorescence image sequences 300 s in duration (movies) were acquired from imaging field during perfusion with normal KRB solution. Movies were acquired and saved in multi-tiff format and processed and analyzed with Fiji (Image J version 1.52 g; National Institutes of Health). Fluo-4 is a single wavelength dye and its fluorescence is a function of dye concentration, illumination pathway, and $[Ca^{2+}]$i. Nonetheless, our experiments are designed to maximize fluorescence changes associated to fluctuations of $[Ca^{2+}]$i. Raw movies were converted to ΔF movies: $\Delta F = F(i) - F_0$, where F_0 is the result of averaging the first five frames of the sequence, and F(i) represents each (i) fluorescence image of the set. No attempts were made to calculate absolute $[Ca^{2+}]$i from these data. The values obtained are expressed as arbitrary fluorescence units. Regions of interest (ROIs) were drawn around selected cells that showed spontaneous or induced fluorescence increases (SD > 5 ± 0.5). These ROIs were used for single-cell quantification of ΔF over time.

Solution exchange

KRB solution was continuously applied to the recording chamber (2 ml/min) by a gravity-fed perfusion. To assess the presence of functional VGCCs, a high $[K^+]$ solution (KCl 120 mM, NaCl 20 mM, $CaCl_2$ 2 mM, and HEPES 10 mM, pH = 7.4) was pressure applied (10 psi; 0.5 s) via a glass puffer pipette (tip diameter ~ 7 μm) connected to a Picospritzer II device (General Valve, Fairfield, NJ) and placed within 100 μm from the surface of the slice with a micromanipulator. Control experiments showed that with this procedure, the external medium surrounding the slice surface is replaced within 100 ms.

Immunofluorescence of ovarian frozen sections

Three mice from each stage of the estrous cycle were injected with a terminal dose of pentobarbital (60 mg/kg, I.P.) and perfused transcardially with 50 ml of phosphate-buffered saline (PBS, 0.1 M), and then with 50 ml of ice-cold 4% paraformaldehyde in PBS. Ovaries were then removed, cleaned, and post-fixed in 4% paraformaldehyde in PBS for 5 h at 4°C. Thereafter, they were placed overnight in 10%, 20%, and 30% sucrose solution in PBS. Finally, they were included in Tissue-Tek (Sakura Finetek) for sectioning in a cryostat (Leica Microsystems CM1900, Wetzlar, Germany). Frozen sections (10 μm in thickness) were then mounted on superfrost glass slides (Fisher Scientific). Frozen sections were washed with PBS and incubated with a blocking solution (2% BSA (weight/volume)) and permeabilized with 0.1% triton 100 in PBS for 30 min at room temperature. After washing with PBS, sections were incubated in a humid chamber for 24 h in the dark at 4°C with one of the following primary rabbit antibodies from Alomone Labs (Jerusalem, Israel): anti Ca_V 2.1 (α1A; validation number 2039764, lot # AN-09), anti Ca_V 2.2 (α1B; validation number 2039766, lot # AN-015), anti Ca_V 1.2 (α1C; validation number 2039771, lot # AN-19) or anti Ca_V 1.3 (α1D; validation number 2039775, lot # AN-09), together with goat anti-SMAα (vascular smooth muscle cell marker α actin) at a 1:250 dilution (validation number 10980764, lot # PA5–18292; Thermo Scientific, Rockford, IL). In separate experiments, sections were incubated with primary goat antibodies against Ca_V 3.1, Ca_V 3.2, and Ca_V 3.3 (validation numbers: 660887, 2259540, and 660891: lot # Sc-16259, Sc-16264, and Sc-16261, respectively; Santa Cruz Biotechnology, Inc. Dallas, TX) at a dilution of 1:250 in PBS. Each of the anti Ca_V 3 subunits gave specific, but weak staining, with patterns indistinguishable from one another. To increase the sensitivity of detection, the immunostaining was carried out with antibodies raised against the three subunits α1G, α1H, and α1I combined.

Sections were washed and incubated for 2 h at room temperature with a $F(ab')_2$ Alexa 488 fraction of donkey anti-rabbit IgG (1:150 dilution, validation number 2340586 cat # 705–006-147; Jackson ImmunoResearch Lab, West Grove, PA) and $F(ab')_2$ Alexa 647 fraction of donkey anti-goat IgG (H + L) (1:150 dilution; validation number 2340386 cat # 705–006-152; Jackson ImmunoResearch Lab) in PBS. Finally, stained sections were washed with PBS and mounted with Dako Glycergel (Dako North American, Inc., CA) for microscopic observation. Several negative controls were required to achieve a reliable double-immunolabeling. Negative control of Ca_V primary antibodies was accomplished by pre-adsorbing each of them with the corresponding synthetic antigenic peptides (2 μg peptide per 1 μg antibody). This procedure completely blocked specific immunofluorescence. In addition, incubation with either secondary antibody alone produced weak, nonspecific fluorescence. Possible interactions between unmatched secondary antibodies were ruled out by incubating samples: first with the rabbit primary anti-CaV antibody, or the goat anti-SMAα, and then with the Alexa 488 F(ab')2 fraction of donkey anti-rabbit IgG and Alexa 647 F(ab')2 fraction

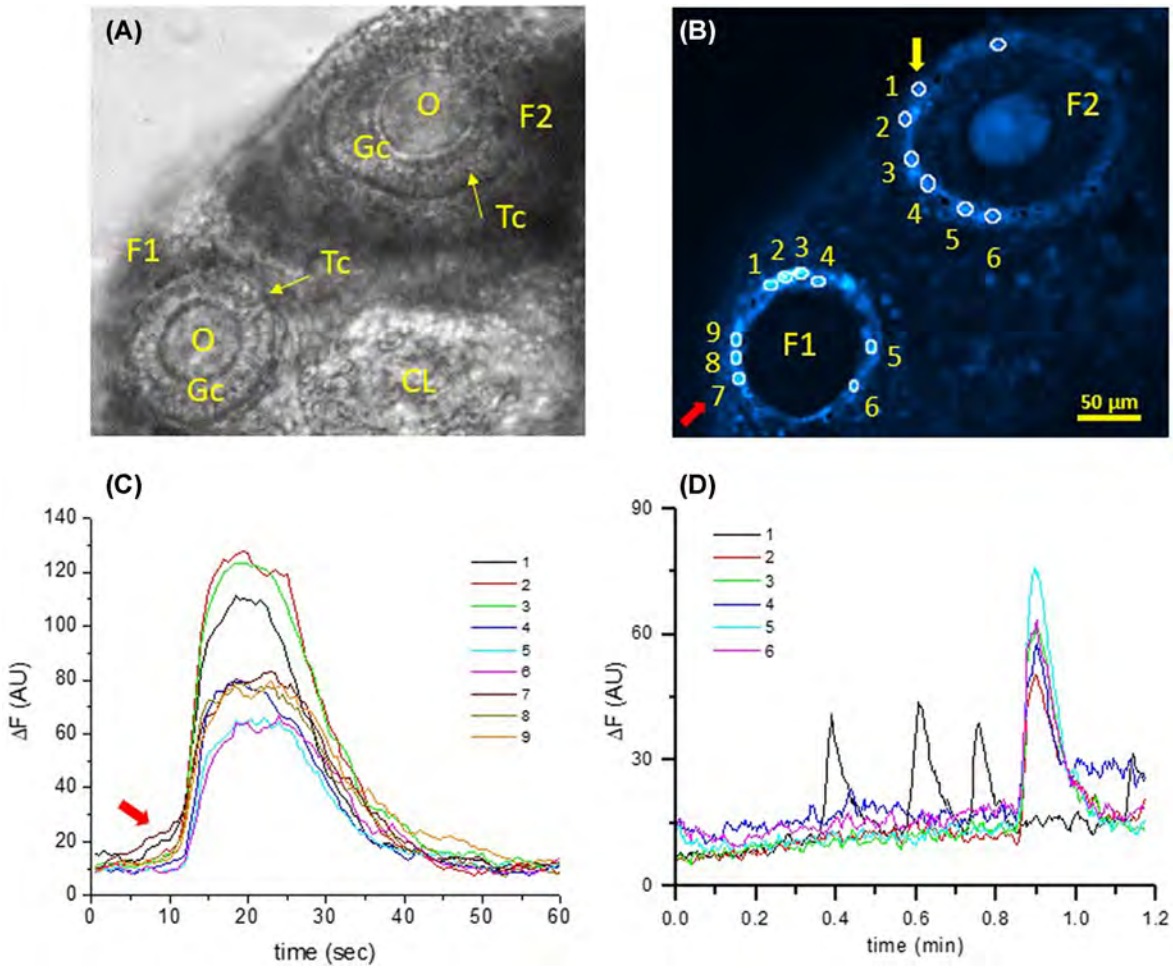

Figure 1. Spontaneous $Ca^{2\pm}$ fluctuations in intact ovarian follicles. (A) Bright-field image of a living mouse ovarian slice. Two intact primary follicles (F1 and F2) are shown. GC: granulosa cells. TC: theca cells. O: oocyte; CL corpus luteum. A 500-frame-long ΔF movie was obtained (see Methods section). (B) Standard deviation image (SD) where regions of interest (ROIs) were drawn on individual cells. (C) ΔF recordings corresponding to follicle # 1 that involves the whole external theca (ROIs 1 to 9). Cell # 7 (red arrow) shows an early response that propagates clockwise, reaching cell # 6 after a delay of ~ 1.2 s. (D) ΔF recordings in follicle #2 also show a spontaneous synchronous Ca^{2+} fluctuation in five out of six TCs. Cell #1 that shows random, unrelated Ca^{2+} spikes.

of donkey anti-goat IgG. As expected, reaction with rabbit primary anti-CaV antibody gave fluorescence at 488 nm excitation, but not at 647 nm excitation and with the presence of goat anti-SMAα antibody gave fluorescence at 647 nm excitation, but not at 488 nm excitation (data not shown).

Mounted sections from three mice were viewed by epifluorescence microscopy, and a representative section from each condition was chosen for analysis and display. Images were acquired with an LSM700 Zeiss confocal laser scanning microscope (Gottingen, Germany), equipped with a 20x/1.0 NA Plan Apochromat water-immersion objective, Samples were excited for Alexa 488 with an Argon-488 nm laser, 490–600 emission range and MBS 488/543 and for Alexa 647 an He/Ne-633 nm laser, 650–750 emission range and MBS 543/633. Exposures were adjusted according to range of fluorescence intensities of each primary antibody, and then imaging parameters (laser power, gain, and pinhole size) remained fixed throughout the session of observation of each set of ovarian section. Images were acquired with Leica ZEN blue software and stored in CVS or TIFF image format (8 bits, 1024 × 1024 pixels). For reconstruction of a complete ovarian section, 1024 × 1024 pixels images were acquired using the "tile scan mode" and a motorized stage. Each tile corresponds to the image summarizing 15 z-stack images spaced by 1 micron. In our case, a tile of 6 × 6 frames was required to completely map an ovarian section. Raw images were normalized so that no more than 0.1% of pixels were saturated. Some of the figures were digitally processed (i.e. multiplied by a factor of 1.25 or 1.5) to emphasize certain aspects or weakly stained structures that are difficult to appreciate. As a result, some areas may appear saturated. However, for the digital quantification performed with some images (see below) we took care that the pixel intensities of the areas involved were far for saturation. Fluorescence quantification was carried out with Fiji ImageJ v.1.52 [20]. The mean fluorescence intensity (arbitrary units) was determined in six different areas of interest on every structure present (either ovarian follicles or corpora lutea [CL]) in each ovarian section. The mean fluorescence measured on CL or GC was used to calculate the fluorescence ratio CL/GC.

Results

Spontaneous follicle Ca^{2+} fluctuations in living ovarian slices

The bright-field image of a living ovarian slice obtained from a mouse in metestrus shows two intact primary follicles (Figure 1A, F1 and

INFORME DE LABORES 2019

Table 1. Incidence of voltage-gated Ca^{2+} signals in ovarian slices at different stages of the estrous cycle

	Proestrus	Estrus	Metestrus	Diestrus	**Total**
Number of follicles recorded	66	72	157	164	459
Number of follicles with spontaneous Ca^{2+} signals	7	4	12	19	42
% of follicles with Ca^{2+} signals	**1.53**	**0.87**	**2.61**	**4.14**	**9.18**
Number of follicles recorded	31	25	31	60	147
Number of follicles with induced* Ca^{2+} signals	4	2	4	8	18
% of follicles with induced* Ca^{2+} signals	**2.72**	**1.36**	**2.72**	**5.44**	**12.24**

* High K^+ depolarization-induced Ca^{2+} signals

F2). Ca^{2+} signals, in the form of ΔF movies, were obtained with confocal microscopy and in fluo-4 loaded ovarian slices (see the Methods section). Supplementary Movie 1 (SM1) displays spontaneous Ca^{2+} fluctuations observed in both follicles. The oocyte from follicle # 2 showed a spontaneous Ca^{2+} oscillation. Regions of interest were drawn in the standard deviation (SD) image, which summarizes the events of the entire movie (Figure 1B). These ROIs correspond to individual cells that showed large ΔF fluctuations. ΔF recordings from ROIs drawn on follicle #1 are shown in Figure 1C. This spontaneous Ca^{2+} fluctuation involves the whole external theca, as nine cells at different locations activate at once. A closer examination reveals that cell #7 had an early small response (red arrow) followed by a large ΔF signal that propagated clockwise, and until after a delay of about 1.2 s, cell #6 is reached and the wave stops. Follicle #2 also showed a spontaneous Ca^{2+} fluctuation. The ΔF recordings in Figure 1D show that five out of six TCs are recruited. Cell #1 shows random, unrelated Ca^{2+} spikes. Ca^{2+} fluctuations of the external theca layer in ovarian follicles is a relatively infrequent phenomenon. Its incidence in ovarian slices from mice at different stages of the estrous cycle is summarized in Table 1. The percentage of follicles with theca Ca^{2+} oscillations ranged from 0.87 to 4.14%, with the highest frequency observed in diestrus. From 459 follicles examined, 42 showed theca Ca^{2+} oscillations.

Spontaneous oocyte Ca^{2+} signals in intact follicles from living ovarian slices

Bright-field and fluorescence images (Figure 2A and B, respectively) were obtained from a slice containing two intact secondary follicles. The oocyte from the larger follicle displayed the spontaneous Ca^{2+} oscillations shown in Figure 2C. Similar "spike-like" fluctuations resulting from Ca^{2+} influx and release from intracellular stores have been reported in isolated oocytes, where they trigger spontaneous exit from diplotene and M-II arrest (reviewed in [21]). Nonetheless, this is the first report where such oscillations have been observed in *intact* secondary follicles from acutely isolated mammalian ovarian slices. In a different slice, the oocyte of another follicle displayed four Ca^{2+} oscillations over the course of several minutes, as depicted in the inset of Figure 2D. The first two of such oscillations can be observed in Supplementary Movie 2 (SM2). Interestingly, these oscillations begin in the edge of the oocyte, spreading inwards as a wave. Figure 2E shows the traces of ΔF over time of the first oscillation, obtained from the ROIs drawn in the inset. ROI # 1 is the initiation site, and the Ca^{2+} wave reaches ROIs 4–5 with a delay of ~2.5 s. The image sequence in Figure 2F illustrates the initiation and spreading of the Ca^{2+} wave during the first Ca^{2+} oscillation. Strictly speaking, oocyte Ca^{2+} signals cannot be explained by the expression of specific Ca^{2+} channel subunits.

Depolarization-induced Ca^{2+} signals

Spontaneous Ca^{2+} oscillations of the TCs layer are fast, appear abruptly, and spread rapidly, properties that are reminiscent of excitable tissues. We conjectured that the opening of VGCCs could be involved in these phenomena. Figure 3A illustrates the result of applying with a puffer pipette a depolarizing solution to an ovarian slice (see the Methods section). In the SD image in Figure 3B, 12 cells were chosen to examine Ca^{2+} signals triggered by the stimulus. Cells 9 and 10, located directly in front of the pipette tip respond first, with a large Ca^{2+} signal. Then, with a 5 s delay, TCs 1 to 8 respond with a rapid, synchronous Ca^{2+} rise. Notice that cells 11 and 12, located away from the pipette tip, also respond to the depolarizing stimulus. The incidence of voltage-gated Ca^{2+} signals in ovarian slices at different stages of the estrous cycle is summarized in Table 1. They were observed more frequently in diestrus (5.4%). Out of 147 follicles examined, 18 responded with Ca^{2+} signals. These experiments suggest the presence of functional VGCCs in specific populations of the ovarian cells *in situ*. Further studies should focus on the physiological and pharmacological characterization of these Ca^{2+} signals.

It is remarkable that GCs do not exhibit spontaneous Ca^{2+} fluctuations nor responses to the depolarizing stimulus, even though the expression of VGCCs has been reported in porcine, chicken, and human GCs [11–14, 16, 17], and both LH/FSH and hCG trigger elevations of $[Ca^{2+}]i$ in GCs that stimulate steroid production [28–30]. Conversely, porcine TCs in vitro display diverse forms of $[Ca^{2+}]_I$ signaling in response to increasing doses of LH, from single spikes to spike-plateau and oscillations.

Immunofluorescence of ovarian frozen sections

Metestrus-diestrus

Ca_V 1.2 (α1C). The presence of L-type, sustained dihidropyridine-sensitive Ca^{2+} currents has been amply documented in GCs from mammalian ovary by both electrophysiology and molecular biology. The tissue distribution of Ca_V 1.2 in metestrus-diestrus (the catabolic or quiescent phases of the cycle, see below) was examined first. Figure 4A illustrates the specific immunolabeling for Ca_V 1.2 and smooth muscle actin (SMAα) in the same ovarian section (A_1 and A_2, respectively). As expected, SMAα immunostaining labels a layer of smooth muscle cells in the theca externa surrounding ovarian follicles (Figure 4A_2) and CL, forming a network of interconnected smooth muscle cells (Figure 4A_2). Ca_V 1.2 immunostaining is widely distributed throughout the ovary, with some regions showing stronger labeling than others, like unidentified stromal cells in the ovarian medulla (Figure 4A_1, yellow arrows; see Figure 5A). Also, the GCs adjacent to the basal lamina of ovarian follicles appear more intensely labeled (Figure 4A_1, red arrows). Higher magnifica-

INFORME DE LABORES 2019

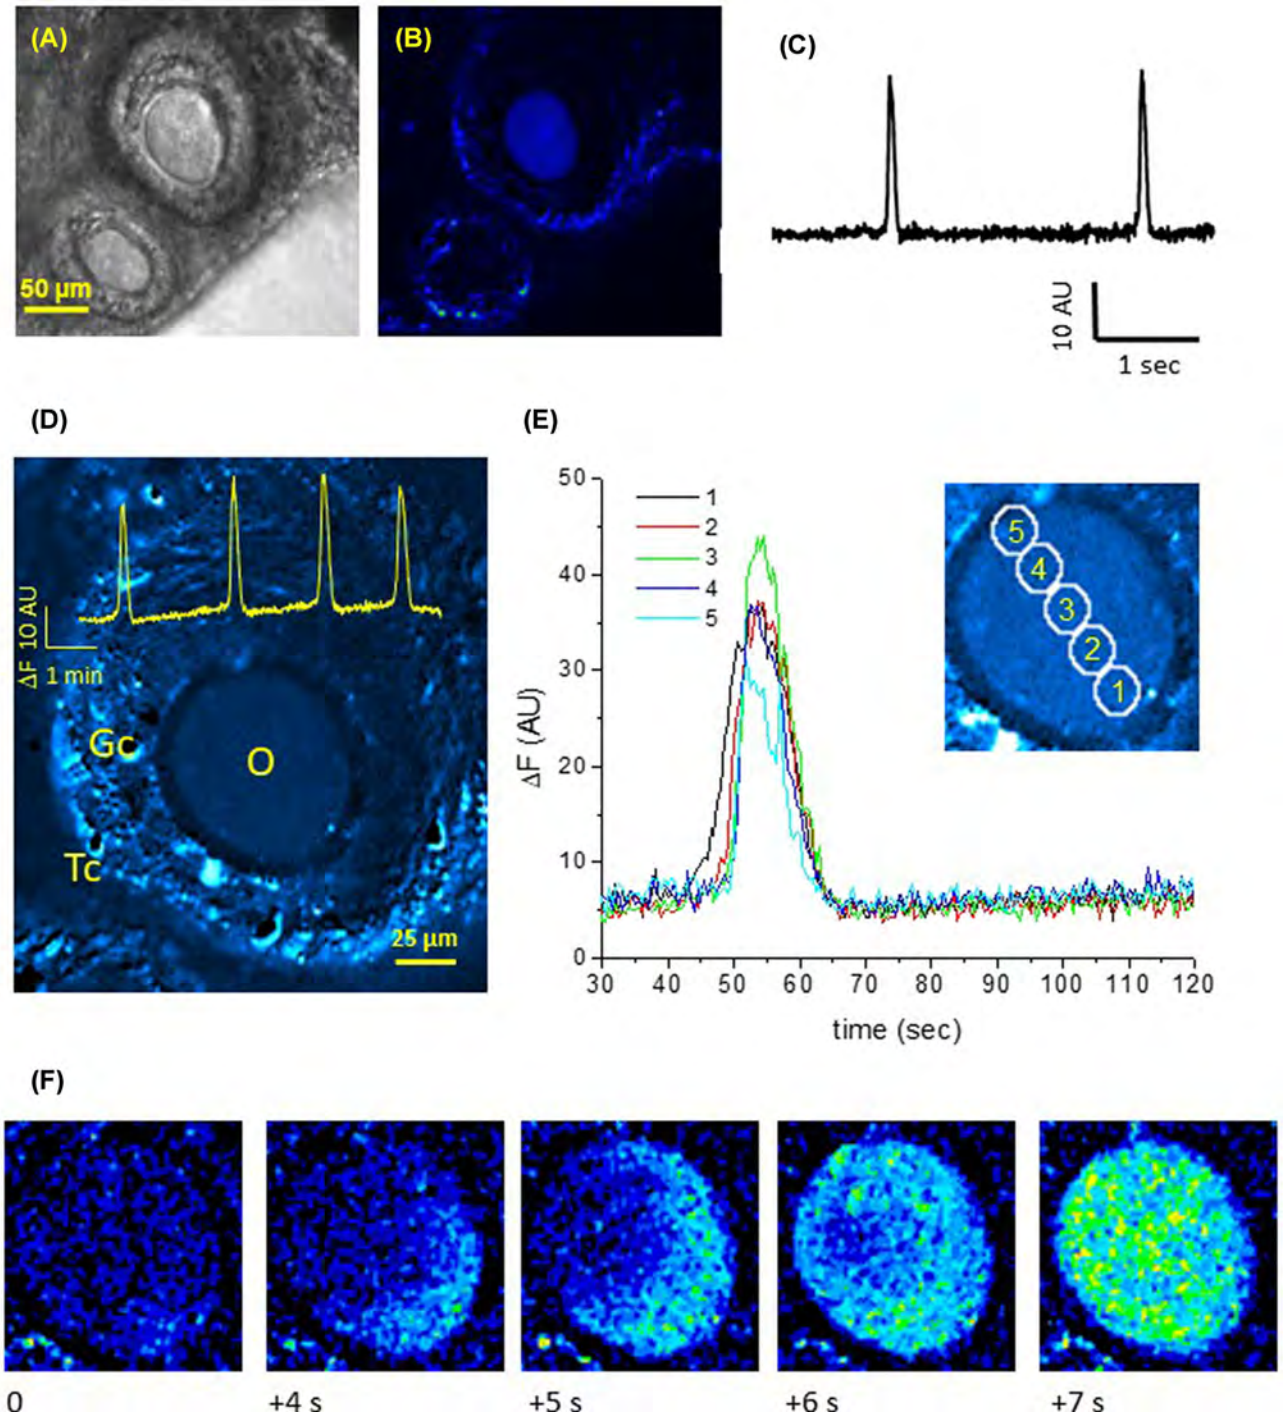

Figure 2. Spontaneous $Ca^{2\pm}$ fluctuations in intact oocytes. (A and B) Bright-field and fluorescence images were obtained from a slice containing two intact secondary follicles. (C) Spontaneous Ca^{2+} oscillations recorded from the oocyte in the larger follicle. (D) Another follicle where the oocyte displayed four Ca^{2+} oscillations (inset). (E) ΔF recordings over time of the first of such oscillations, obtained from the ROIs on the inset. Clearly the oscillation begins in the perimeter of the oocyte (ROI #1), spreading inwards as a wave. (F) Image sequence showing the initiation and spreading of the Ca^{2+} wave during the first Ca^{2+} oscillation. The labels indicate the corresponding delay in seconds.

tion shows that GCs labeling is confined to the plasma membrane (Figure 5B and D; GC), and that the stronger peripheral staining of ovarian follicles (Figure 4A_1, red arrows) is a palisade of elongated GCs perpendicular to the basal lamina (Figure 5B, red stars). In some cases, this pattern is somewhat confusing: they appear as slender processes, running perpendicular to the basal lamina and extending several microns inward, forming ramifications (Figure 5B and D, yellow stars). The fluorescence intensity of several ROIs comprising these peripheral GCs was measured and compared with ROIs of the same size from the central GCs. A ratio of peripheral versus

INFORME DE LABORES 2019

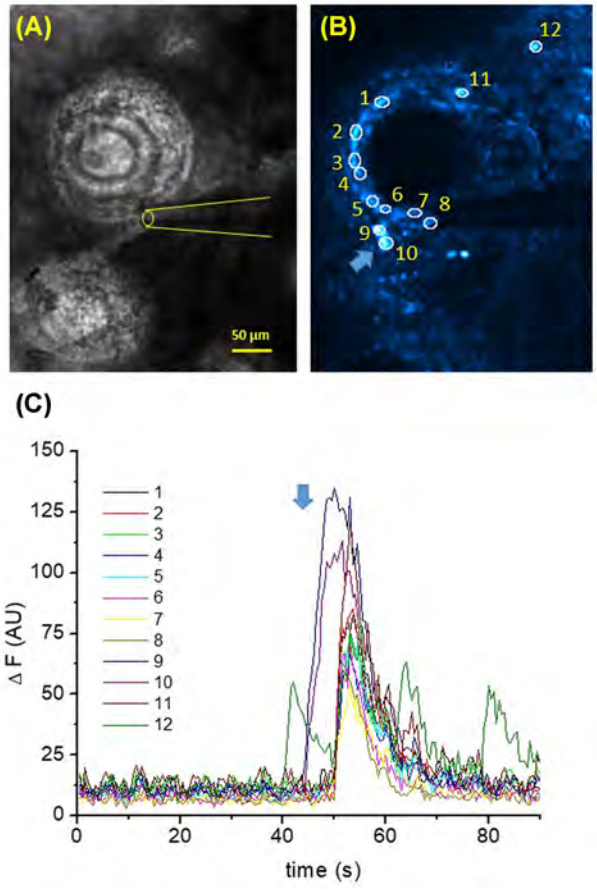

Figure 3. Ca^{2+} signals triggered by a depolarizing stimulus in an ovarian slice. (A) Bright-field image of an ovarian slice with two intact follicles. The diagram indicates the position of the puffer pipette (B) SD image showing the 12 ROIs that were chosen to record Ca^{2+} signals triggered by the depolarizing stimulus (see Methods section). (C) ΔF recordings over time from cells 1 to 12. Cells 9 and 10, located directly in front of the pipette tip, respond promptly to the application of the high K^+ solution (10 psi; 0.5 s; time indicated with a blue arrow) with large Ca^{2+} signals Then, after a ~5 s delay, TCs 1 to 8 also respond with a rapid, synchronous Ca^{2+} rise. Even cells 11 and 12, located away from the pipette tip, respond to the depolarizing stimulus with about same delay.

central GCs staining of 1.77 is obtained (i.e. peripheral GCs were 77% brighter than central GCs). In contrast, CL cells are stained more uniformly (Figure 5C and D, CL). Excluding the periphery of ovarian follicles, central GCs and CL cells are stained similarly (Figure 5C and D). Accordingly, when the mean fluorescence was measured in GCs and CL cells, a ratio CL/GC of 1.06 was obtained (see Table 2). Slender processes resembling unmyelinated nerve fibers can be seen both inside (Figure 5C, red arrows) and around CL and ovarian follicles (Figure 5D, red arrows). As shown in Figure $4A_3$, Ca_V 1.2 and SMAα do not co-localize, implying that this subunit is absent in perifollicular smooth muscle cells (see below).

Ca_V 1.3 (α1D). The expression pattern of Ca_V 1.3 (α1D) subunits, also capable of generating L-type, dihidropyridine-sensitive Ca^{2+} currents in model systems, was examined next (Figure $4B_1$). Similar to Ca_V 1.2, unidentified medulla stromal cells show cytoplasmic Ca_V 1.3 staining (Figure $4B_1$, yellow arrows; see also Figure 6A). Both CL cells and GCs are weakly labeled (Figure $4B_1$: see Figure 6B, GC and CL). Hence, a fluorescence ratio CL/Gc of 1.12 close to unity is obtained (see Table 2). Ca_V 1.3 and SMAα do not co-localize either (see Figure $4B_3$). The anti-Ca_V 1.3 antibody labels GCs in the plasma membrane and CL cells in the cytoplasm (Figure 6B). Thin filaments reminiscent of unmyelinated nerve fibers are not stained with the Ca_V 1.3 antibody (Figure 6B).

Ca_V 2.1 (α1A). Ca_V 2.1, α1A pore-forming subunits expressed in model systems lead to the generation of HVA sustained Ca^{2+} currents also known as P/Q-type Ca^{2+} channels blocked by ω-Agatoxin IVA and abundantly expressed in CNS neurons. The presence of this Ca^{2+} channel subunit had not been previously reported in ovarian tissue. Ca_V 2.1 and SMAα immunolabeling are illustrated in Figure $4C_1$ and C_2, respectively. Ca_V 2.1 staining is markedly nonuniform (Figure $4C_1$): similarly to Ca_V 1.2 and Ca_V 1.3, Ca_V 2.1-positive cells are present in the stroma of ovarian medulla (Figure $4C_1$, yellow arrows). Ca_V 2.1 does not co-localize with SMAα either (see Figure $4C_1$–C_3). However, Ca_V 2.1 immunostaining differs from Ca_V1.2 and Ca_V1.3 in that CL cells are more intensely stained than GCs (see Figure $4C_1$). Accordingly, a fluorescence ratio CL/GC of 1.4 is obtained (CL cells are 40% brighter than GCs; see Table 2). Nerve fiber-like structures inside and around CL and ovarian follicles are not stained with Ca_V 2.1 (data not shown).

Ca_V 2.2 (α1B). Ca_V 2.2 (α1B) subunits expressed in heterologous cell models generate an HVA sustained Ca^{2+} current, also known as N-type, typically expressed in central and peripheral neurons and blocked by ω-Conotoxin GVIA. The presence of this Ca^{2+} channel subtype had not been previously reported in ovarian tissue. Ca_V 2.2 and SMAα immunolabeling are shown in Figure $4D_1$ and D_2, respectively. The expression pattern of Ca_V 2.2 is weak throughout the entire ovary, but unequivocally strong in smooth muscle cells, as revealed by their characteristic anatomical disposition, and evident co-expression with the anti SMAα antibody (see Figure $4D_1$–D_3). This is the only Ca^{2+} channel subunit detected in the ovarian perifollicular smooth muscle. The distribution of Ca_V 2.2 and SMAα immunolabeling are shown enlarged in Figure 6C and D. Co-localization is obvious for the most part, but few cells are only positive to Ca_V 2.2 and other cells are only SMAα positive. The presence of this α1 Ca^{2+} channel subunit had not been reported in ovarian tissue nor in any other smooth muscle cells elsewhere [22]. Although in Ca_V 2.2 labeling is weak in most ovarian structures, CL cells are more intensely stained than GCs from ovarian follicles (Figure $4D_1$; see Figure 6C and D, GCs and CL); accordingly, a mean fluorescence ratio CL/GC of 1.24 (a 24% difference) is obtained (see Table 2). The apparent staining of some oocytes (i.e. Figure 6C and D) probably results from nonspecific antibody binding or autofluorescence of either cytoplasmic lipid droplets or reduced nicotinamide adenine dinucleotide (phosphate) (NAD(P)H) [31].

Proestrus. The anabolic phase of the estrous cycle begins with proestrus, which is characterized by maximal concentrations of plasma of 17β-estradiol, which triggers the surge of pituitary LH and FSH that initiates ovulation and the recruitment of the next cohort of ovarian follicles, respectively. Since proestrus is the stage of maximal stimulation of the ovary, we examined the expression pattern of Ca_Vs subunits in comparison with the more quiescent stage of metestrous-diestrus.

Ca_V 1.2 (α1C). The ovarian distribution of Ca_V 1.2 and SMAα immunostaining in proestrus are shown in Figure $7A_1$ and A_2, respec-

A_2: smooth muscle actin (SMAα) staining: A_3: images A_1 and A_2 superimposed. B_1: Ca_V 1.3 staining; yellow arrows, unidentified stromal cells in the ovarian medulla. B_2: SMAα staining: B_3: images B_1 and B_2 superimposed. C_1: Ca_V 2.1 staining; yellow arrows, unidentified stromal cells. C_2: SMAα staining. C_3: images C_1 and C_2 superimposed. D_1: Ca_V 2.2 staining. D_2: SMAα staining. D_3: images C_1 and C_2 superimposed. (a, b) Regions of interest shown enlarged in Figure 6C and D. Denotation of labels in A_2, B_2, C_2, and D_2: asterisk: primary follicle, 2: secondary follicle, 3: secondary preantral follicle, 4: antral follicle 5: preovulatory follicle. CL: corpora lutea. Atr: atresic follicle. Calibration bar: 200 μm.

tively. Ca_V 1.2 does not co-express with SMAα (compare Figure 7A_1 and A_2 and Figure 7A_3). The stronger staining of GCs observed in the periphery of ovarian follicles is present (red arrows in Figure 7A_1) although less conspicuously than in metestrous-diestrus (compare Figure 7A_1 and 4A_1). An obvious difference between metestrous-diestrus and proestrus is that in the latter, CL cells are considerably more intensely stained than GCs (Figure 7A_1). The mean fluorescence ratio CL/GC of 1.49 is obtained(a 49% difference; see Table 2). Thin nerve fiber-like structures positive to Ca_V 1.2 can be seen inside and around CLs and ovarian follicles, but they are less distinctly labeled than in metestrous-diestrus (data not shown).

Ca_V 1.3 (α1D). The staining patterns of Ca_V 1.3 and SMAα in proestrus are illustrated in Figure 7B_1 and B_2, respectively. Ca_V 1.3 does not co-localize with SMAα (see Figure 7B_1–B_3). This is confirmed by comparing the SMAα-positivity of smooth muscle fibers of the hilum (Figure 7B, yellow asterisk) and the lack of Ca_V 1.3 staining of the same structure (Figure 7B_1, yellow asterisk). In metestrus-diestrus, Ca_V 1.3 staining is weak and uniform throughout the ovary (see Figure 4B_1), while in proestrus the expression pattern of Ca_V 1.3 is rather inhomogeneous. As seen in Figure 7B_1, CL cells display the strongest immunostaining, while GCs from ovarian follicles show the weakest. In general, the staining pattern of Ca_V 1.3 and Ca_V 1.2 in proestrus is similar (compare Figure 7A_1 and B_1), but the staining ratio CL/GC for Ca_V 1.3 is higher than for Ca_V 1.2 (fluorescence ratio CL/GC of Ca_V 1.3 in proestrus gave 2.04 (a 104% difference: see Table 2)).

Ca_V 2.1 (α1A). The staining patterns of Ca_V 2.1 and SMAα in proestrus are shown in Figure 7C_1 and C_2, respectively. As seen in the composite image in Figure 7C_3, SMAα-positive cells apparently do not co-express Ca_V 2.1, although smooth muscle fibers in the hilum appear weakly Ca_V 2.1 positive (blue asterisk in Figure 7C_1 and C_2). Ca_V 2.1 immunofluorescence pattern in proestrus is similar to that of metestrous, except for the absence of stained cells in the stroma and the even greater differential expression of CL cells versus

INFORME DE LABORES 2019

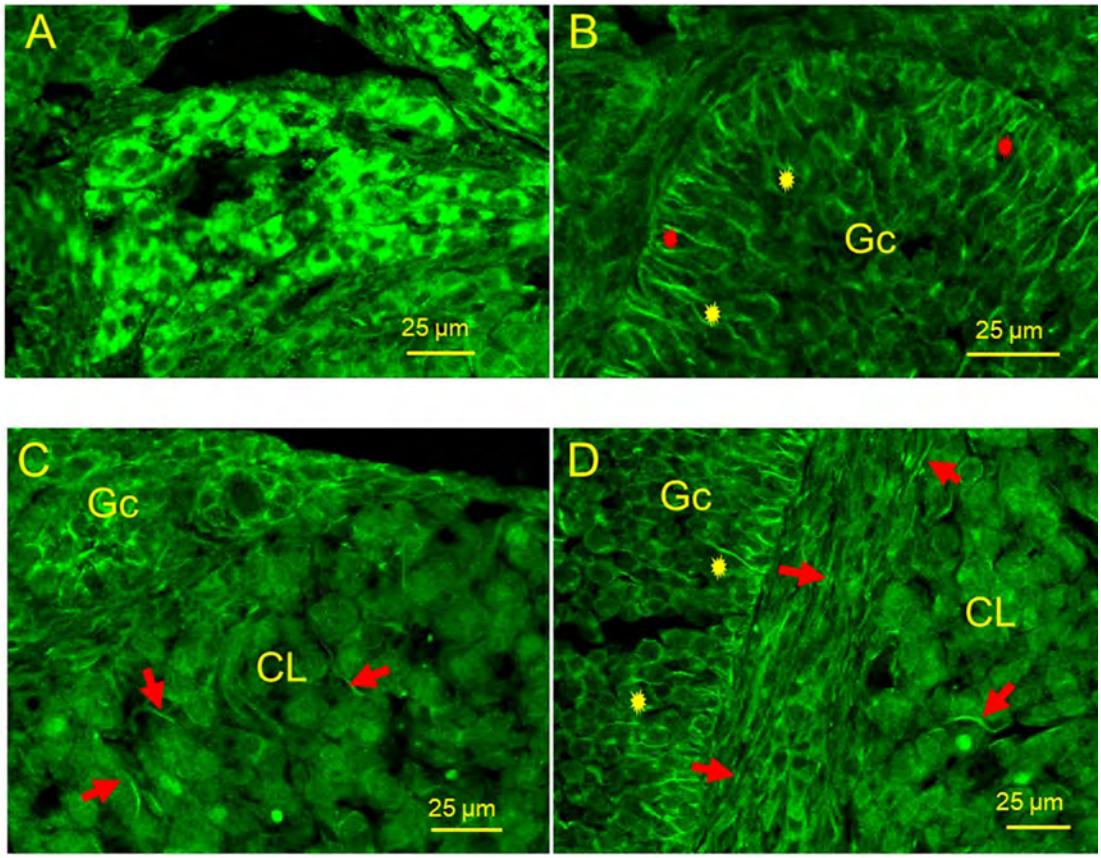

Figure 5. High magnification images of Ca_V 1.2-specific immunolabeling. (A) Unidentified Ca_V 1.2 positive stromal cells in the ovarian medulla (Figure 1A_1; red arrows). (B, C) Ca_V 1.2 labeling of GCs from ovarian follicles is confined to the plasma membrane (Gc). (B) Peripheral staining from ovarian follicles results from the presence of elongated GCs arranged perpendicularly to the basal lamina (red stars), or processes extending into the follicle, forming ramifications (yellow stars). (C, D) Red arrows: thin processes, resembling unmyelinated nerve fibers seen both inside and around CL and ovarian follicles. (D) Corpora lutea (CL) cells express Ca_V 1.2 uniformly in the cytoplasm while GCs express Ca_V 1.2 in the plasma membrane.

GCs. The expression pattern of Ca_V 2.1 in proestrus appears to be an *intensification* of that observed in metestrus-diestrus (compare Figures 4C_1 and 7C_1). Accordingly, the Ca_V 2.1 ratio CL/GC rises from 1.39 in metestrus-diestrus to 2.08 in proestrus (see Table 2).

Ca_V 2.2 (α1B). Ca_V 2.2 and SMA*α* immunostaining patterns in proestrus are illustrated in Figure 7D_1 and D_2, respectively. It is obvious that Ca_V 2.2 immunostaining in proestrus co-localizes with SMA*α*, as judged by the network-like perifollicular disposition around ovarian follicles and CL, and the unequivocal superposition of red and green signals in Figure 7D_3. Nonetheless, in proestrus, not only the smooth muscle cells express Ca_V 2.2 but also the CL. In fact, the differential Ca_V 2.2 staining of CL versus GC in proestrus is stronger than in metestrus-diestrus (compare Figures 4D_1 and 7D_1). Hence, the mean Ca_V 2.2 fluorescence ratio CL/GC obtained in proestrus is 1.94 (see Table 2).

Estrus

Estrus begins shortly after the pre-ovulatory LH/FSH surge and ends the anabolic phase of the cycle. It has been reported that these gonadotropins, as well as hCG, increase intracellular Ca^{2+} concentration in GCs and stimulate steroid production. Thus, we wondered if the expression pattern of VGCCs in the ovary changes as a result of gonadotropin stimulation. As shown in Figure 8, the overall staining pattern for Ca_V 1.2, Ca_V 1.3, and Ca_V 2.1 in the ovary at estrus suggests a *decline* from the peak expression reached in proestrus, and a progressive return to the baseline condition of metestrus-diestrus. The staining intensity of Ca_V 1.2 and Ca_V 1.3 in estrus is still higher in CL cells compared to GCs. The mean fluorescence CL/GC ratio obtained is 1.34 for Ca_V 1.2 and 1.91 for Ca_V 1.3 (see Table 2). The stronger Ca_V 1.2 labeling of GCs in the edge of ovarian follicles described in Figure 1A_1 is also noticeable in Figure 8A_1. In estrus, Ca_V 2.2 antibody strongly labels smooth muscle cells just as in metestrus-diestrus, but labeling now appears more dispersed throughout the ovary (see Figure 8D_1), with a fluorescence ratio CL/GC still relatively high: 1.31 (see Table 2; compare Figures 7D_1 and 8D_1). Bundles of Ca_V 2.2-positive and SMA*α*-positive smooth muscle cells are clearly visible in a bundle of smooth muscle cells from the hilum (Figure 8D1 and D2, blue asterisks).

Regardless of the stage of estrus cycle, Ca_V 1.2 and SMA*α* do not co-localize, implying that this subunit is absent from perifollicular smooth muscle cells. This result is contrary to reports that Ca_V 1.2 subunits are expressed in smooth muscle. To address this issue, an ovarian section containing a large longitudinal section of the oviduct was immunostained both with Ca_V 1.2 and SMA*α*. The doubly stained section is shown in Supplementary Figure S1. In the smooth muscle fibers of the oviduct Cav1.2 and SMA*α* clearly co-localize (see orange and yellow hues in Supplementary Figures S1A_1 and

Presence of LVA α1 subunits (Ca_V 3.1; α1G, 3.2; α1H and 3.3; α1I)

Metestrus-diestrus

The predominant Ca^{2+} current component recorded with patch-clamp electrophysiology from porcine, chicken, and human GCs is an LVA T-type Ca^{2+} current. Pore-forming α1 subunits Ca_V 3.1, Ca_V 3.2, and Ca_V 3.3, when expressed in heterologous systems, generate LVA T-type Ca^{2+} currents with slightly different biophysical properties. Accordingly, mRNAs encoding for Cav 3.2 subunits have been isolated from human luteinized GCs [16, 17]. Experiments conducted with antibodies raised against each of the three Ca_V 3 α1 subunits (Ca_V3.1, Ca_V3.2, and Ca_V3.3) separately gave weak, but specific staining patterns indistinguishable from one another. To increase the sensitivity of detection, the immunostaining was carried out with antibodies raised against the three subunits combined. Figure 9A illustrates the Ca_V 3 staining pattern in mouse ovarian sections in metestrus-diestrus. This pattern resembles that of Ca_V 2.1 (compare Figures 9A and 4C_1): the strongest Ca_V 3 immunostaining is visible in medulla stroma cells (red arrows in Figure 9A and A_1) and perifollicular stroma cells forming an incomplete multilayer envelope around secondary and antral follicles (see blue arrows in Figure 9A and A_3). It would be interesting to perform double immunolabeling (Ca_V 3 and Ca_V 2.1) to find out if these subunits are co-expressed in the same cells.

Some of the cells associated with ovarian follicles probably correspond to TCs, which produce the androgen substrate required for ovarian estrogen biosynthesis [23]. Substantial Ca_V 3 staining is present in CL (Figure 9A and A_2: CL), in agreement with electrophysiological and molecular biology studies in human luteinized GCs [16, 17]. In contrast, the staining is weak or absent in GCs from ovarian follicles (yellow asterisks in Figure 9A and A_3). Accordingly, the fluorescence ratio CL/GC obtained is 1.84 (84% difference; see Table 2). Ca_V 3-positive cells do not display the characteristic anatomical arrangement of smooth muscle cells (compare Figures 9A and 4D_2, which are contiguous sections from the same ovary); nonetheless, we cannot rule out that some perifollicular Ca_V 3-positive cells are smooth muscle cells, since RNAs encoding for Ca_V 3 α1 subunits have been reported in smooth muscle cells [24]. Substantial differences in the distribution pattern or Ca_V 3 expression were observed along the estrous cycle (see below).

Proestrus

Ca_V 3 immunostaining in proestrus is shown in Figure 9B. At this stage of the estrus cycle, CL staining is stronger than in any other ovarian structure, while ovarian follicles (yellow asterisks) display the weakest. Accordingly the fluorescence ratio CL/GC obtained is 4.2 (324% difference). Staining of CL cells is not uniform, with patches of stronger immunofluorescence (Figure 9B and B_1). Another peculiarity of proestrus is that medullar and interfollicular stroma cells are weakly stained. Ca_V 3-positive flat cells around CL and ovarian follicles are probably theca and/or smooth muscle cells. In Figure 9B, a cross section of the hilum is weakly Ca_V 3-positive (red asterisk). This structure is clearly SMAα-positive as seen in the adjacent section from the same ovary (Figure 5B_2 and C_2). Bundles of smooth muscle-like fibers in a longitudinal section (red arrow in Figure 9B and B_2) are also Ca_V 3-positive.

INFORME DE LABORES 2019

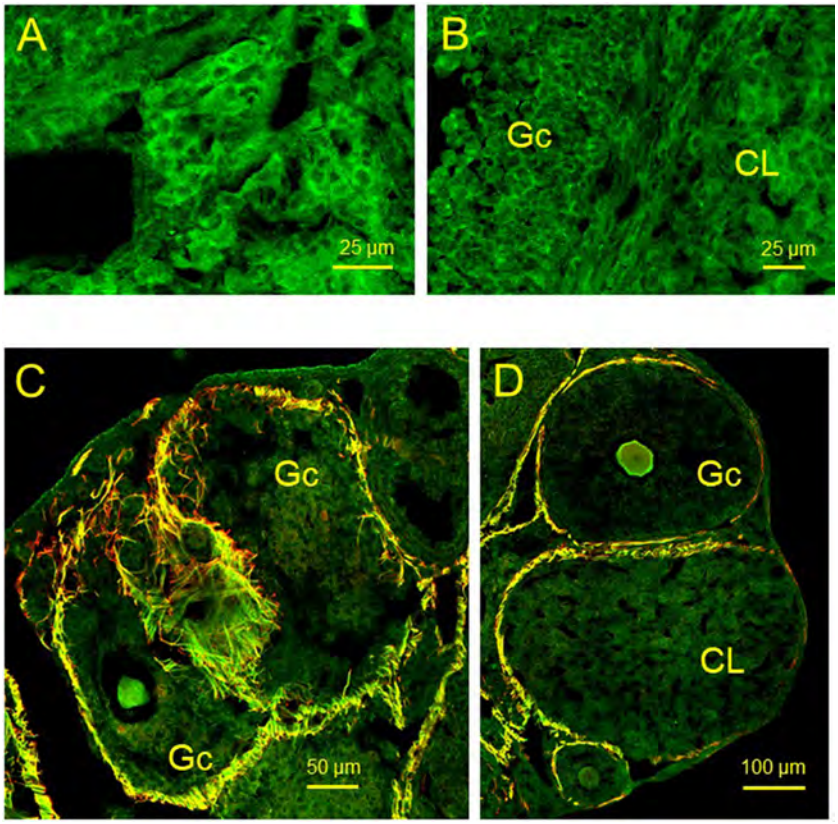

Figure 6. High magnification images of Ca_V 1.3- and Ca_V 2.2-specific immunolabeling. (A) Ca_V 1.3-positive unidentified medulla stromal cells (Figure 1B_1, yellow arrows). (B) Both corpora lutea (CL) and granule cells (Gc) are weakly labeled with anti-Ca_V 1.3. Thin filaments resembling unmyelinated nerve fibers are not stained with anti-Ca_V 1.3. (C, D) High magnification views of regions *a* and *b* from Figure 1D_3. (C) Superimposed images of Ca_V 2.2 and SMAα staining reveal that both labels co-localize, but some cells are either positive to Ca_V 2.2 only and other cells are SMAα positive only. (D) Ca_V 2.2 labeling is weak in most ovarian structures, but CL cells are more intensely stained than GCs from ovarian follicles.

Estrus

The distribution pattern of Ca_V 3 immunostaining in estrus is shown in Figure 10. Here, the most remarkable feature is the intense cytoplasmic staining of mesenchymal and interfollicular cells in the ovarian stroma, stronger than CL and ovarian follicles (asterisks: see Figure 10A). At this stage both CL and GCs from ovarian follicles are stained weakly. This is the only example where GCs are slightly more intensely stained than CL cells (fluorescence ratio CL/GC = 0.77). The majority of the strongly stained Ca_V 3-positive cells in the stroma are round and arranged in clusters (see Figure 10A_1). Perifollicular cells of the internal theca are also stained, but their anatomical distribution is not compatible with that of smooth muscle cells (Figure 10A_2). In fact, smooth muscle cells of the hilum (red asterisk in Figure 10A) are negative for Ca_V 3 at this stage of the estrous cycle.

Discussion

The estrous cycle in mice comprises a series of physiological and behavioral events that repeats every 4–6 days throughout the reproductive life span unless interrupted by pregnancy or anestrus. The cycle length is variable and affected by a number of factors, including stress, diet, and social cues. The estrous cycle affects the entire reproductive tract, and can be regarded as comprised of three phases: *anabolic, catabolic, and quiescent phase*. In the ovary, the anabolic phase concludes with the release of oocytes, while the catabolic phase is characterized by degenerative changes. The quiescent phase is regarded as a resting state of the reproductive tract. The estrous cycle is also classically divided, based on the vaginal smears, into four stages: metestrus, diestrus, proestrus, and estrus [19, 25].

At metestrus, CL formation and atresia are widespread among the remaining follicles. Metestrus-diestrus can be regarded as the quiescent phase of the cycle: estradiol concentrations remain low, and in the absence of mating, CL does not activate completely, producing little progesterone. Metestrus-diestrus represents the catabolic phase of the cycle and coincides with declining concentrations of estradiol following ovulation. Near the end of diestrus, ovarian follicles begin to grow [25]. Proestrus signals the increase in functional activity of both GCs and TCs: the peak concentration of estrogen (typically late in the afternoon) triggers the pre-ovulatory surge of pituitary LH and FSH. LH stimulates in TCs a cAMP signaling pathway that increases the synthesis of key steroidogenic enzymes that synthesize androstenedione, which diffuses across the basal lamina and into the ovarian follicle. FSH by a cAMP-mediated mechanism then stimulates the synthesis of aromatase cytochrome P450 and 17 β-hydroxysteroid dehydrogenase in GCs. With these enzymes, GCs metabolize androstenedione to estradiol. Estrus ends the anabolic phase of the cycle. During estrus the female is receptive to the male because of the elevated concentration of estrogen. Estrus typically occurs during the night, and mating occurs near the mid-point of the dark phase. Ovulation also occurs during estrus, about 12 h after the LH surge.

Role of Ca^{2+} in ovarian endocrine cell function

A role for extracellular Ca^{2+} in hCG-induced ovulation was discovered more than 30 years ago in the perfused rabbit ovary: the infusion the Ca^{2+} channel blocker verapamil did not suppress hCG-induced ovulation; however, the infusion of hCG together with EGTA (an extracellular Ca^{2+} chelator) greatly reduces the ovulatory efficiency (17%) in comparison to hCG alone (80%) [26]. Reducing the extracellular Ca^{2+} concentration disrupts LH-stimulated steroidogenesis [27] in isolated ovarian cells, possibly by preventing transmembrane Ca^{2+} influx. Also, hCG-induced, but not basal testosterone production was impaired in goldfish follicles after incubation with Ca^{2+}-deficient media, or a variety of Ca^{2+} channel blockers (verapamil, nifedipine, nicardipine, and $CoCl_2$) [18].

More recent reports showed that inhibitors of VGCCs attenuate hCG-induced steroid production in co-cultures of TCs and GCs from carp [28]. These findings are consistent with earlier reports showing that application of FSH elevates intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in swine GCs [29–31], and that both diacylglycerol and inositol trisphosphate trigger $[Ca^{2+}]_i$ mobilization in pig GCs [32]. Strong $[Ca^{2+}]_i$ elevations, like those induced by exposure to the Ca^{2+} ionophore A23187, increase by fivefold the release of progesterone in rat GCs in culture [33] and by twofold basal testosterone and estradiol (E_2) production in co-cultured TCs/GCs from carp. A23187 also significantly potentiates hCG-stimulated production of testosterone and E_2 [32].

It has been reported that both LH/FSH and hCG trigger elevations of $[Ca^{2+}]$i in GCs that stimulate steroid production [28–30]. Porcine TCs in vitro display diverse forms of $[Ca^{2+}]_I$ signaling in response to increasing doses of LH, from single spikes to spike-plateau and oscillations. Removal of extracellular Ca^{2+} or treatment with 100 μM $CoCl_2$ inhibits the maintenance, but not the initiation of these responses, suggesting the participation of VGCCs [35]. The

diversity of the $[Ca^{2+}]$i signals elicited by LH in porcine TCs is in contrast to the stereotyped responses to LH in GCs where $[Ca^{2+}]_i$ oscillations have not been reported nor observed here [34]. The increased expression of Ca_V3 $\alpha1$ subunits in TCs and its relative scarcity in GCs and CL cells (see figure 4A_3) could explain in part these functional differences. In the neuronal cell line NG108–15, overexpression of $Ca_V3.1$ and $Ca_V3.3$ channels produces repetitive action potentials and spontaneous $[Ca^{2+}]$i oscillations [36]. It remain to be seen if the presence of Ca_V3 Ca^{2+} channels underlies the spontaneous and depolarization-induced Ca^{2+} signals recorded in the TCs layer (Figures 1 and 2).

Types of VGCC identified electrophysiologically in ovarian endocrine cells

Using patch-clamp electrophysiology in isolated cultured GCs, a LVA T type Ca^{2+} current has been recorded in porcine and chicken GCs [12, 13]. A smaller HVA L-type Ca^{2+} current component has also been identified in chicken GCs [14, 15]. More recently, Ca^{2+} channels expressed in human GCs (cultured human luteinized GCs obtained from patients undergoing in vitro fertilization) were characterized electrophysiologically, and their regulation by hormones [16] and muscarinic receptors [17] was examined. The most predominant Ca^{2+} current, identified by their biophysical and pharmacological properties, is a LVA T-type Ca^{2+} current [16,17]. In some GCs a high-voltage-activated Ca^{2+} current sensitive to dihydropyridine (L-type Ca^{2+} current) was also recorded. These results are similar to those obtained in GCs from other species [12–14]. These electrophysiological findings are supported by the isolation of mRNAs encoding pore-forming $\alpha1$ subunits Cav 3.2 and Cav 1.2 (T- and L-type Ca^{2+} channels, respectively). Further progress in this area requires (1) identification of the different subtypes of VGCCs present in the ovary *in situ*, (2) evaluation of the expression levels of Ca^{2+} channels subunits in the different types of ovarian cells and their variations along the estrous cycle, and (3) characterization of $[Ca^{2+}]_i$ signals

displayed by ovarian cells in situ at different stages of the estrous cycle, including responses to LH and FSH. Our study represents a crucial step forward in addressing these important questions.

In the "quiescent" stage of the estrous cycle (metestrous-diestrus), L-type Ca^{2+} channel subunits Ca_V 1.2 (α1C) and Ca_V 1.3 (α1D) are widely distributed throughout the ovary, particularly in stromal medulla cells, GCs, and CL cells. At the follicle's edge GCs are more strongly labeled with Ca_V 1.2. Ca^{2+} channel subunits abundant in nerve cells (P/Q-type and N-type Ca^{2+} channel subunits Ca_V 2.1 and Ca_V 2.2) are reported for the first time in ovarian tissue. The former are abundant in stroma and CL cells, while the latter are unequivocally expressed in perifollicular smooth muscle cells. Subunits encoding LVA T-type Ca^{2+} channels (Ca_V 3.1, 3.2, and 3.3) are expressed in CL cells and medullar and interfollicular stroma cells, with GCs displaying the weakest staining. Remarkably, the expression level of HVA and LVA Ca^{2+} channel subunits fluctuates significantly along the estrus cycle. The ratio CL/GC is used here for comparison (see Table 1), but other ovarian structures like mesenchymal and interfollicular stroma cells also display marked variations. The description of the Ca^{2+} signals and the expression of VGCCs in the ovary and their variations throughout the estrous cycle opens a new chapter in ovarian physiology.

A relevant question is how VGCCs participate in ovarian endocrine cells. For instance, GCs have a resting membrane potential of around –42 mV [3, 4]. At this potential more than 75% of LVA T-type Ca^{2+} channels should be inactivated [16]. Nonetheless, voltage clamp experiments indicate that a small fraction (about 4%) of these channels could be available for activation, because of the "window current" formed at the crossing between activation and inactivation curves [16]. Thus, a small, continuous Ca^{2+} influx across the plasma membrane is likely to occur at the GC resting potential [37]. Interestingly, chicken GCs, which possess a more negative resting potential than mammalian GCs, are excitable, i.e. capable of generating Ca^{2+}-dependent action potentials [11]. It is conceivable that luteinized mammalian GCs could become excitable as the expression level of VGCCs increases, in some cases up to 240% in proestrus (see Table 1). The large spontaneous Ca^{2+} fluctuations reported here strongly suggest that the resting membrane potential of perifollicular TCs is probably more negative than –55 mV, so that a significant number of Ca^{2+} channels are available for activation. A similar

INFORME DE LABORES 2019

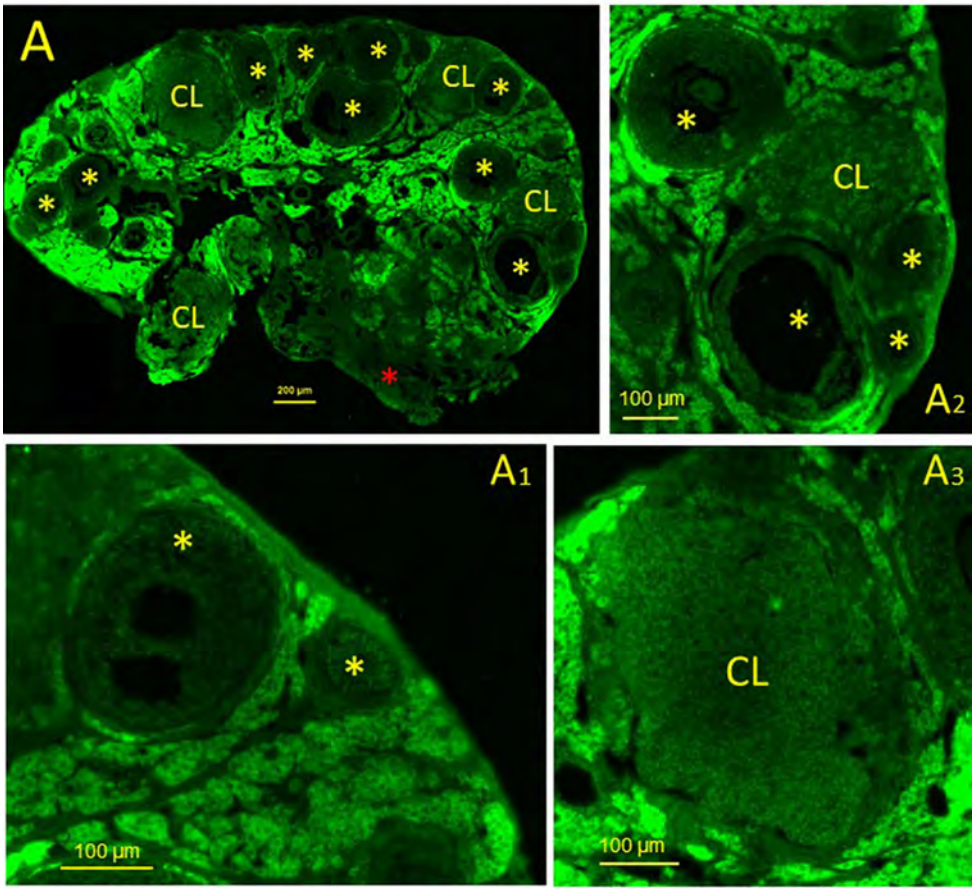

Figure 10. (A) Ca_V 3 immunostaining of mouse ovarian sections in estrus. At this stage, the most notable feature is the cytoplasmic staining of mesenchymal and interfollicular cells in the ovarian stroma, much stronger than corpora lutea (CL) and ovarian follicles (yellow asterisks). Smooth muscle cells of the hilum (red asterisk) are Ca_V 3-negative. A_1: detail of Ca_V 3-positive cells in the stroma. A_2: Ca_V 3-positive perifollicular cells of the internal theca do not resemble perifollicular smooth muscle cells. Corpus luteum (CL) is slightly more stained than ovarian follicles (yellow asterisks). A_2: enlargement of corpus luteum and surrounding Ca_V 3-positive stromal cells.

study focused on the ovarian expression of intracellular Ca^{2+} release channels—inositol 1, 4, 5-trisphosphate receptors and ryanodine receptors [38] together with plasma membrane Ca^{2+} ATPases (PMCA) and sarco-endoplasmic reticulum Ca^{2+} ATPases (SERCA)—is needed to achieve a comprehensive view of the Ca^{2+} handling proteins responsible for Ca^{2+} homeostasis and dynamics [39].

The functional role of the numerous transporting molecules responsible for Ca^{2+} mobilization and signaling in the different ovarian cell types is only begging to unfold. Moreover, in spite of convincing evidence that the disruption of Ca^{2+} homeostasis underlies certain ovarian malignant phenotypes [40–42] and the identification of Ca^{2+} transporters whose altered function underlies different pathologies, a rational therapeutic application of these findings is still at its infancy. However, the rapid development of the field warrants the development of improved molecular Ca^{2+} transport-targeting tools for diagnosis and treatment of ovarian cancer and other reproductive pathologies. This study represents an important step in the definition of the specific physiological questions that need to be addressed.

Supplemental data

Supplementary data are available at *BIOLRE* online.

Supplementary Figure S1. A_1: An ovarian section containing a large longitudinal section of the oviduct (white star) was immunostained both with Ca_V 1.2 and SMAα. **A2** and **A3**: Higher magnification images of the areas marked in yellow in **A_1**. SMAα-positive interfollicular smooth muscle fibers are not stained with the Cav1.2 antibody (A_2, yellow arrow). In contrast, Cav1.2 and SMAα clearly co-localize in the smooth muscle fibers of the oviduct (see orange and yellow hues in A_3).

Supplementary Movie 1 (SM1). This file shows the spontaneous Ca^{2+} fluctuations recorded in two follicles. A series of confocal microscopy images (ΔF movie) was obtained from an ovarian slice containing two intact follicles (F1 and F2 in Figure 1). This movie represents 1.2 min of recording. Scale 100 μm.

Supplementary Movie 2 (SM2). This file shows two spontaneous Ca^{2+} fluctuations in the oocyte from an intact follicle. These oscillations begin in the edge of the oocyte, spreading inwards as a wave. See additional information in Figure 2D–F. Scale 20 μm.

ABSTRACT

Benign prostatic hyperplasia (BPH) is an aging-related and progressive disease linked to an up-regulation of α_1-adrenoceptors. The participation of EGF receptors (EGFR) in the GPCRs' signalosome has been described but so far data about the contribution of these receptors to prostatic stromal hyperplasia are scanty. We isolated and cultured vimentin-positive prostate stromal cells obtained from BPH patients. According to intracellular Ca^{2+} measurements, cell proliferation and Western blotting assays, these cultured hyperplastic stromal cells express functional α_1-adrenoceptors and EGFR, and proliferate in response to the α_1-adrenoceptor agonist phenylephrine. Interestingly, in these cells the inhibition of EGFR signaling with GM6001, CRM197, AG1478 or PD98059 was associated with full blockage of α_1-adrenoceptor-mediated cell proliferation, while cell treatment with each inhibitor alone did not alter basal cell growth. Moreover, the co-incubation of AG1478 (EGFR inhibitor) with α_{1A}/α_{1D}-adrenoceptor antagonists showed no additive inhibitory effect. These findings highlight a putative role of EGFR signaling to α_1-adrenoceptor-mediated human prostate hyperplasia, suggesting that the inhibition of this transactivation cascade could be useful to reduce BPH progression.

1. Introduction

Benign prostatic hyperplasia (BPH) is a progressive condition that affects aging men. The epithelial and stromal hyperplasia occurs in the periurethral prostatic transition zone favoring the occurrence of the lower urinary tract symptoms suggestive of BPH (LUTS/BPH). Prostate enlargement and the enhanced prostatic smooth muscle contraction are responsible for the static and dynamic components of BPH, respectively, and both components reduce bladder outflow favoring urinary retention [1–3].

The α_1-adrenoceptor belongs to the G protein-coupled receptors (GPCRs) family being composed by three receptor subtypes known as α_{1A}-, α_{1B}- and α_{1D}-adrenoceptors [4]. The adult human prostate expresses mainly α_{1A}-adrenoceptors particularly in the stroma, and its expression is increased during BPH [5–9]. Therefore, it is well accepted that the mechanism underlying the BPH-related raise of smooth muscle contraction involves mainly the increased prostate expression of α_{1A}-adrenoceptors [5,6]. On the other hand, α_{1D}-adrenoceptors have been implicated in prostatic cell proliferation [6,10,11] and their mRNA expression is also up regulated in BPH patients [5,6]. α_{1A}-adrenoceptor blockers such as tamsulosin and silodosin are the first line drugs to treat low to moderate LUTS/BPH favoring bladder emptying, but they do not modify prostatic enlargement progression or the risk of BPH complications [12].

The etiology of prostate enlargement is complex with some evidence pointing to the involvement of metabolic and endocrine disorders, including roles of peptide growth factors, such as the epidermal growth factor (EGF) [2,13,14].

Two large families of membrane receptors, namely GPCRs and receptor tyrosine kinases, regulate cell proliferation among other cell functions. G protein-coupled receptors' signaling involves canonical and non-canonical pathways. In the case of α_1-adrenoceptor, the canonical pathway mediated by G protein involves the activation of phospholipase Cβ and the increase of intracellular Ca^{2+} [4]. On the other hand, the non-canonical receptor signaling activates other intracellular pathways including growth factor receptors signaling in a

process known as transactivation [15–17].

The participation of EGF receptors in the GPCRs' signalosome is essential for physiological and disease-related conditions such as mitogenesis, inflammation, and muscle contraction [17–23]. Moreover, the pioneer work of Oganesian and colleagues [23] showed that the constitutive activity of naturally occurring variant of α_{1A}-adrenoceptor transfected to Rat-1 fibroblasts lead to cell proliferation. EGF receptors belong to the ErbB/HER protein family and are expressed in normal human prostate mainly in the epithelial cells [24,25]. However, the expression of these receptors in prostate from BPH patients expands to stromal cells [25], where α_1-adrenoceptors are mainly expressed, with EGF inducing stromal cell proliferation [26,27]. Besides, the availability of EGF receptor ligand depends on matrix metalloproteinases activity, which in turn may be activated by GPCR [15,24].

Previously we characterized two *N*-phenylpiperazine derivatives named LDT3 and LDT5 as new α_{1A}/α_{1D}-adrenoceptor antagonists, and we showed that the α_{1D}-adrenoceptor antagonist BMY7378 as well as LDT3 and LDT5 inhibit human prostatic cell proliferation *in vitro* [28,29], while another α_{1D}-adrenoceptor antagonist, naftopidil, inhibits cell proliferation *in vivo* [30]. Therefore, we explored the possible role of α_1-adrenoceptor-mediated transactivation of EGF receptor leading to mitogenesis of stromal cells from BPH patients. Our results indicate that EGF receptor transactivation is involved in the α_1-adrenoceptor-mediated proliferation of human hyperplastic prostatic cells providing insight into the understanding of BPH physiopathology, and suggesting that this transactivation cascade could be a target to reduce BPH progression.

2. Material and methods

2.1. Cell culture maintenance

Prostate tissue samples were collected from three patients with LUTS/BPH during transurethral resection and immediately placed in ice-cold Dulbecco's modified Eagle's medium (DMEM) and transported to the Laboratory. The inclusion criteria of the patients were IPSS greater than 8 points, 50–70 years of age and PSA less than 2.5 ng/mL. Exclusion criteria were: previous prostatic surgery, prostate cancer, use of drugs that interfere with the function of adrenoceptors such as antagonists, anti-androgens and antidepressants, herbal extract, bladder catheter or neurogenic bladder. This study was approved by the ethics committee of the Federal University of Rio de Janeiro (UFRJ; CAAE-0029.0.197.000–05; 2009) and all experiments were performed in accordance with relevant guidelines and regulations. Informed written consent was signed by all donors. Briefly, prostate tissue was washed in phosphate buffer solution (PBS) before minced. The prostate fragments (1 mm^3) were added to DMEM supplemented with 10% heat-inactivated fetal bovine serum containing 1 mg/mL type I collagenase. Tissue specimens were dissociated by magnetic bar constant stirring for 2–4 h at 37 °C. The recovered cells were seeded in 25 mm^3 flasks cultured in DMEM supplemented with 10% heat-inactivated fetal bovine serum, 1% sodium pyruvate and 1% penicillin/streptomycin (100 IU/mL and 0.1 mg/mL, respectively), and fungizone (25 µg/mL) at 37 °C and 5% CO_2. Cells were observed at phase contrast microscopy (x250) to analyze morphology and confluence. At sub-confluence (approximately 90% confluence), cells were harvested using 0.05% trypsin/EDTA, and plated. A homogeneous stromal cell culture was obtained after six passages. The subsequent steps were the sub-culture of the cells and storage at −70 °C until use. Cells were used at 9^{th} - 11^{th} passage since the initial cell harvesting [31].

Rat-1 fibroblasts stably expressing human α_{1A}- or α_{1D}-adrenoceptors were cultured in DMEM supplemented with 10% fetal bovine serum, 300 µg/mL neomycin analogue G418 sulfate, 1% penicillin/streptomycin (100 IU/mL and 0.1 mg/mL, respectively; 37 °C, 5% CO_2) until confluence. The receptor density of α_1-adrenoceptors estimated with [^{3}H]-prazosin is in the range of 1.0–1.5 pmol/mg of protein [28].

2.2. Immunofluorescence assay

To analyze BPH cell morphology we used an anti-human cytokeratin (CK) monoclonal antibody (Dako) and anti-vimentin (Vim) monoclonal antibody (Sigma) as primary antibodies. For this procedure, 2×10^4 cells (11^{th} passage) were plated and incubated for four days. Following, the culture medium was removed and cells were fixed with absolute cold ethanol for 20 min at room temperature, and then washed three times with PBS. The nonspecific binding was blocked with PBS/BSA 5% and then primary antibodies were added to the cultures and incubated for 2 h at room temperature. After that, cells were washed with PBS and incubated for an additional 2 h with goat anti-mouse Alexa 546 secondary antibody (Invitrogen). Cell nuclei were counterstained with DAPI (Santa Cruz Biotechnology). Finally, cells were washed in distilled water and mounted on histological slides with *N*-propylgallate (Sigma). Negative control conditions were performed by omitting the primary antibodies. No reactivity was observed when the primary antibody was absent. Images were captured using an inverted microscopy (Olympus IX81) and a Hamamatsu ORCA-R2 digital CCD camera using a 40× objective.

2.3. Intracellular [Ca^{2+}] measurement

In order to verify if primary stromal cell cultures from BPH patients express functional α_1-adrenoceptors we used a fluorimetric assay to measure the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$), a robust marker of the canonical Gq signaling. Cells were serum-starved overnight. In the next day, cells were washed with PBS and loaded with 2.5 µM fura-2/AM in the dark for 60 min at 37 °C in Krebs-Ringer-HEPES solution containing (mM) NaCl 120, KH_2PO_4 1.2, $MgSO_4$ 1.2, KCl 4.75, glucose 10, $CaCl_2$ 1.2, HEPES 20, and 0.05% bovine serum albumin (pH 7.4). Thereafter, the cells were washed to remove the unincorporated dye, detached by gentle trypsinization, centrifuged (200 × *g*, 7 min, 4 °C), and incubated (10^6 cells/condition) for 100 s (baseline) and then stimulated with 10 µM noradrenaline (NA) or 100 µM phenylephrine (Phe). The antagonists (BMY7378, 50 nM; WB4101, 50 nM or tamsulosin, 5 nM) were pre-incubated for 100 s before addition of the agonists, and their concentrations were previously defined based on their affinities [28]. Fluorescence measurements were performed at 340 and 380 nm excitation wavelengths and 510 nm emission wavelength, with a chopper interval set at 0.5 s, using an Aminco-Bowman Series 2 luminescence spectrometer (Rochester, NY). Peak fluorescence values were used for data analysis, and the

intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) was calculated, as described by Grynkiewicz et al. [32].

2.4. Cell growth assays

Briefly, cells (3×10^3 cells/well) were plated in 96-well plates in serum-free DMEM for 24 h. Sub-confluent cells were kept in DMEM (basal) or stimulated with 3 μM phenylephrine (Phe) for 48 h in the absence or presence of GM6001 (10 μM; metalloproteinase inhibitor), CRM197 (200 ng/mL; HB-EGF inhibitor), AG1478 (5 μM; selective EGFR tyrosine kinase inhibitor) or the MEK inhibitor PD98059 (1 μM) added 30 min before addition of the agonist. EGF 100 ng/mL (48 h) was used as positive control. All concentrations were chosen based on their affinities for the targets and previously reported in the literature [19,22]. Alternatively, cells were also treated with 3 μM phenylephrine for 48 h in the absence or presence of LDT3 or LDT5 (50 nM) alone, or in combination with AG1478 (5 μM), added 30 min before. The medium was changed every 24 h with fresh dilutions of drugs. Cell growth was evaluated by counting of viable cells using Trypan blue as an exclusion dye or by the 3-(4,5-dimethythiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay [28]. Otherwise indicated, each assay was performed in quadruplicate to calculate the mean value of one experiment. Data were expressed as the percentage of the basal condition which was considered as 100%.

2.5. Western blot assays

BPH cells (1×10^6) seeded on 6-well plate were incubated with 100 μM phenylephrine (Phe) or 10 μM noradrenaline (NA; in the presence of 1 μM propranolol added 2 min before) for 2, 5, 15, and 30 min in serum free medium. After treatment, cells were lysed with 200 μL of RIPA buffer (150 mM NaCl, 1 mM EGTA, 10% glycerol, 1% Triton X-100, 0.1% SDS, 1.5 mM $MgCl_2$, 10 mM sodium pyrophosphate, 1 mM sodium orthovanadate, 100 mM NaF, 10 mg/mL aprotinin, 10 mg/mL leupeptin, and 50 mM Tris-HCl, pH 7.4) under agitation, centrifuged at 13,000 × *g* for 5 min (4 °C) and the supernatants were used for evaluation of activation (phosphorylation) of extracellular signal-regulated kinases 1 and 2 (ERK 1/2). Protein content was determined according to the method of Lowry et al. Twenty μg of proteins were boiled for 5 min and resolved using 10% SDS/PAGE. After electrophoresis, proteins were transferred to nitrocellulose membranes and incubated for 1 h with Tris buffered saline (TBS) containing 0.1% Tween-20 (TBS-T) and 5% non-fat milk. Then, membranes were washed 3 times in TBS-T and incubated overnight with the primary monoclonal antibodies phospho-p44/p42 MAPK (p-ERK 1/2 Thr202/Tyr204, #9101; 1:1000), or p44/p42 MAPK Total (ERK 1/2, #4695; 1:1000) diluted in TBS-T with 5% non-fat milk at 4 °C with gentle shaking. The peroxidase-conjugated anti-rabbit IgG secondary antibody (#7074; 1:10000) was diluted in cold TBS-T and incubated for 1 h. Membranes were washed in TBS-T and detection of immunoreactivity was performed by enhanced chemiluminescence (ECL, Westar Cyanagen). Protein blot images were scanned and the optical density was obtained using ImageJ software (NIH, USA). The relative expression of p-ERK was normalized in relation to total ERK (also used as loading control).

2.6. Human androgen receptor binding assay

Filtration based radioligand binding assays for human prostate androgen receptors (LNCap cells; catalogue number 0933) using 1 nM [^{3}H]-methyltrienolone (4 °C, 24 h) were performed by Eurofins Cerep SA, France (Study 100018032). Mibolerone (1 μM) was used as positive control and showed an IC_{50} value of 1.9 nM. LDT3 and LDT5 were tested at the final concentration of 1 μM and the results were expressed as the percentage of the specific binding of [^{3}H]-methyltrienolone (considered as 100%).

2.7. Reagents and antibodies

LDT3 and LDT5 were synthesized as previously described [28]. The following reagents were acquired from the sources indicated between parenthesis: (R)-(−)-phenylephrine hydrochloride, (±)-propranolol hydrochloride, (−)-noradrenaline, fungizone, EGF, CRM197 and reagents for RIPA buffer (Sigma Aldrich, USA). Fura 2/AM (Molecular Probes, USA). Dulbecco's modified Eagle's medium (DMEM), fetal

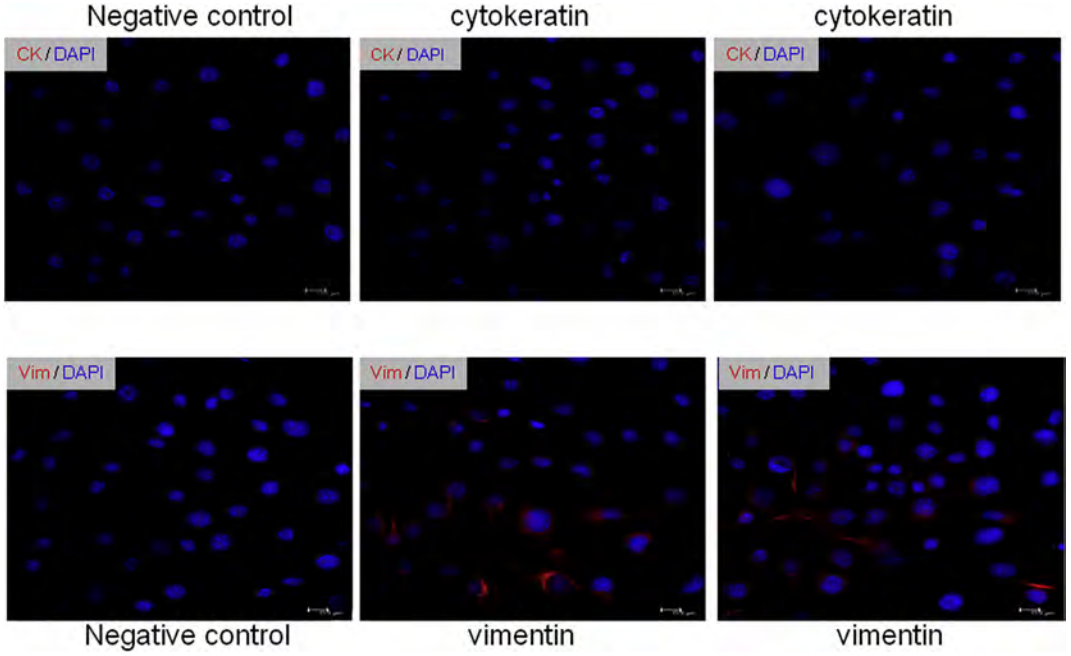

Fig. 1. BPH cells are positive for vimentin and negative for cytokeratin staining. Cells were incubated with anti-human primary monoclonal antibodies against cytokeratin (upper panels, CK) or vimentin (lower panels, Vim, red). In all immunostaining-negative controls, reactions were performed by omitting the primary antibody. No reactivity was observed when the primary antibody was absent. Blue staining = DAPI. Bars = 150 μm, objective 40×. (For interpretation of the references to colour in this figure legend, the reader is referred to the Web version of this article.)

bovine serum (South America), trypsin, penicillin (10000 IU/mL)/ streptomycin (10 mg/mL), PD98059 and other reagents for cell culture (Life Technologies, USA). AG1478 (Calbiochem, USA). GM6001 (Merck Millipore, USA). Rabbit monoclonal primary antibodies against extracellular signal-regulated kinases (ERK) 1/2 (#4695), and phospho-ERK 1/2 (#9101) (Cell Signaling, USA). Monoclonal anti-human cytokeratin antibody (#0821, Dako, USA). Monoclonal anti-human vimentin antibody (#V2258, Sigma Aldrich, USA). Anti-rabbit IgG secondary antibody (#7074, Cell Signaling, USA) and anti-mouse Alexa 546 secondary antibody (#A11003, Invitrogen, USA).

2.8. Statistical analysis

Otherwise indicated, data are expressed as mean and S.E.M. of 3–5 independent experiments. Independent experiments were performed using different primary cell cultures. The significance of the differences among two or more conditions was determined by two-tailed Student's *t*-test or one-way analysis of variance (one way ANOVA), respectively. ANOVA was followed by Dunnett's multiple comparisons test using the software GraphPad Prism 6.0 (Graphpad, La Jolla, CA, USA). Differences were considered statistically significant if $P < 0.05$.

3. Results

3.1. BPH stromal cells express functional α_1-adrenoceptors

The cultured hyperplastic cells are positive for vimentin and negative for cytokeratin staining which is a signature of stromal cells (Fig. 1). The canonical α_1-adrenoceptor signaling is linked to the increase of intracellular Ca^{2+} concentration $[Ca^{2+}]_i$. As shown in Fig. 2, the stimulation of BPH cells expressing native α_1-adrenoceptors with either 100 μM phenylephrine or 10 μM noradrenaline induced similar increments of $[Ca^{2+}]_i$ in relation to basal, which indicates that the receptors are functional. We chose the selective agonist of α_1-adrenoceptor phenylephrine to perform the subsequent experiments.

The agonist specificity for α_1-adrenoceptor was confirmed by measuring the intracellular Ca^{2+} concentration in Rat-1 fibroblasts stably expressing α_{1A}- or α_{1D}-adrenoceptors subtypes, the two adrenoceptor subtypes relevant for BPH. Cell pre-incubation with the antagonists WB 4101 (50 nM; α_{1A}-adrenoceptor antagonist) and tamsulosin (5 nM, $\alpha_{1A/1D}$-adrenoceptor antagonist), but not with BMY7378 (50 nM, α_{1D}-adrenoceptor antagonist), blocked the effect of 100 μM phenylephrine in cells expressing α_{1A}-adrenoceptors, while BMY7378 (50 nM) blocked the agonist effect only in cells expressing α_{1D}-adrenoceptors (Fig. 3A and B).

3.2. The EGF receptor modulates the α_1-adrenoceptor-mediated BPH cell growth

The presence of EGF receptors in the stromal cells was evaluated by cell proliferation. Cells were stimulated with EGF (100 ng/mL) in the absence and presence of an antagonist. As shown in Fig. 4A, the EGF-induced BPH cell proliferation was blocked by the EGF receptor tyrosine kinase inhibitor (AG1478, 5 μM). AG1478 *per se* did not alter basal cell growth discarding a putative cytotoxicity. Interestingly, phenylephrine (3 μM) increased BPH cell proliferation similarly to EGF. Then, in order to evaluate a possible dependence on the EGF receptor for the α_1-adrenoceptor-mediated BPH cell proliferation, we investigated if the blockage of downstream EGF receptor signaling could alter phenylephrine-mediated cell growth.

GM6001 (10 μM) is a pan inhibitor of the matrix metalloproteinases involved in pro-ligand heparin-binding epidermal growth factor (HB-EGF) cleavage, and consequently EGF receptor signaling [23]. GM6001 treatment did not alter the basal cell proliferation but prevented cell proliferation induced by phenylephrine (Fig. 4B), and the specific inhibitor of human HB-EGF, CRM197 (200 ng/mL) [18], had the same effect. The selective EGF receptor tyrosine kinase inhibitor AG1478 (5 μM) also prevented completely the effect of phenylephrine, without altering the basal cell proliferation. Cells were treated with the MEK inhibitor PD98059 (1 μM) which also inhibited cell proliferation in response to phenylephrine (Fig. 4B). Similar qualitative results were obtained using the MTT assay (Fig. 4C). Moreover AG1478, GM6001 and PD98059 blunted the EGF-mediated cell growth (Fig. 4D). None of the inhibitors *per se* inhibited cell growth. Altogether, the inhibition of sequential steps of EGF receptor signaling impaired the proliferative effect of the α_1-adrenoceptor agonist phenylephrine.

3.3. α_1-adrenoceptor agonists induce ERK phosphorylation in BPH cells

Since BPH cell proliferation induced by activation of α_1-adrenoceptor was prevented by the inhibition of EGF receptor signaling, which usually involves activation of the mitogen-activated protein kinase pathway, we then evaluated the impact of phenylephrine on ERK 1/2 activation by quantifying the ratio of phospho-ERK (p-ERK) to total ERK protein. Due to BPH cell limitation, we used only one concentration of phenylephrine (100 μM) which has been used elsewhere to activate ERK 1/2 pathway [33,34]. Moreover, previous data obtained from different cell systems showed that this concentration usually induces the maximal effect of the agonist [33,34].

Phenylephrine stimulated ERK 1/2 activity in stromal BPH cells in a time-dependent manner, and its effect peaked after 15 min. A similar stimulatory effect was also observed with the α_1-adrenoceptor agonist noradrenaline (10 μM, in the presence of propranolol 1 μM). In these experiments, EGF (100 ng/mL, 5 min stimulation) was used as a positive control and it stimulated ERK 1/2 activation (Fig. 5A–C). In isometric contraction assays, 100 μM phenylephrine added in the plateau of the contraction induced by 1 μM 5-HT, and in the presence of 1 μM prazosin, failed to relax rat aorta therefore discarding a putative β-adrenergic effect (*data not shown*). Previously we showed that the selective α_{1D}-adrenoceptor antagonist BMY7378, as well as the α_{1A}-/α_{1D}-adrenoceptor antagonists LDT3 and LDT5, inhibited human hyperplastic prostate stromal cell growth mediated by phenylephrine [28]. Current data showed that AG1478 (5 μM) inhibited the proliferative effect of phenylephrine, and the association with the α_{1A}/α_{1D}-adrenoceptor antagonists LDT3 or LDT5 (50 nM) resulted in similar inhibition suggesting that in this model the EGF receptor pathway is necessary for α_1-adrenoceptor-mediated BPH cell proliferation (Fig. 6). Of note, this inhibitory effect of LDT3 or LDT5 (50 nM) did not involve the inhibition of prostate androgen receptors (AR) since even at a much higher

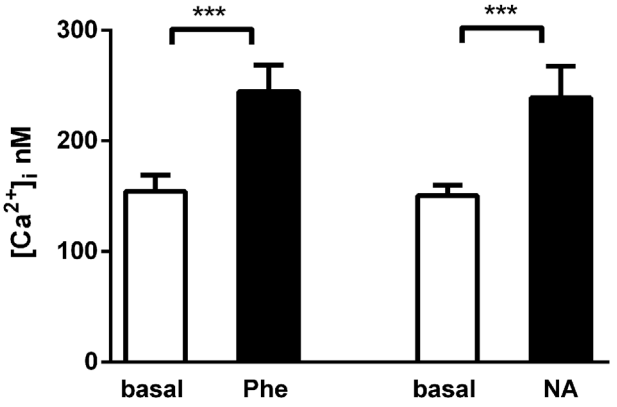

Fig. 2. Phenylephrine and noradrenaline increase intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in hyperplastic prostatic stromal cells obtained from BPH patients. Cells were loaded with 2.5 μM fura-2 AM for 60 min before stimulation with the agonists (10 μM NA, 100 μM Phe). Data were expressed as mean and S.E.M. (n = 7–10 replicates from 3 individual experiments). ***P = 0.007 vs. basal (two-tailed Student's *t*-test). Phe = phenylephrine; NA = noradrenaline.

INFORME DE LABORES 2019

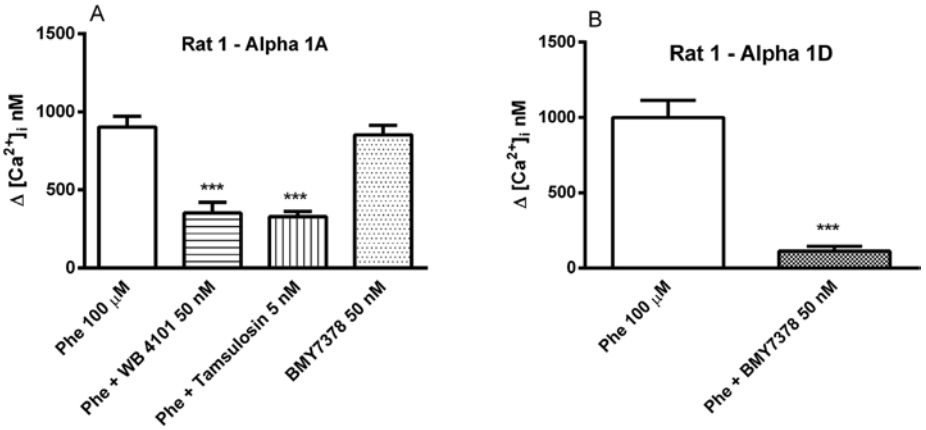

Fig. 3. The increase of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in Rat-1 cells transfected with human α_{1A}- or α_{1D}-adrenoceptors induced by phenylephrine is inhibited by selective antagonists added 100 s before. Cells were loaded with 2.5 μM fura-2 AM for 60 min before stimulation with phenylephrine (100 μM Phe). WB 4101 (50 nM): α_{1A}-adrenoceptor antagonist; tamsulosin (5 nM): $\alpha_{1A/D}$-adrenoceptor antagonist; BMY7378 (50 nM): α_{1D}-adrenoceptor antagonist. Data represent the difference (Δ) between the basal and agonist-induced increase of fluorescence, and were expressed as mean and S.E.M. (n = 6–8 replicates from 3 individual experiments). ***P < 0.001 vs. Phe (A, one way ANOVA followed by Dunnett's multiple comparisons test; B, two-tailed Student's *t*-test).

concentration (1 μM) they did not inhibit the specific binding of the AR agonist (LDT3: 6.9 ± 4.9%, n = 2; LDT5: 17.7 ± 8.1%, n = 2).

4. Discussion

BPH is an aging-related disease linked to an imbalance between prostate cell proliferation and apoptosis, favoring hyperplastic stromal cell growth [35]. Mounting evidence points to the importance of GPCRs for cell proliferation in pathological conditions [17,22,23]. Here we showed that the α_1-adrenoceptor-mediated proliferation of human hyperplastic prostatic stromal cells is fully inhibited by EGF receptor and MEK inhibitors suggesting the transactivation of the EGF receptors by α_1-adrenoceptors as an important event for BPH cell proliferation. To the best of our knowledge this is the first report about the stromal α_1-adrenoceptor-EGF receptor signaling in BPH.

The prostatic stroma makes up a large percentage of prostate volume during BPH, and the use of human stromal cells is considered valuable for BPH studies [35,36]. However, the isolation of stromal

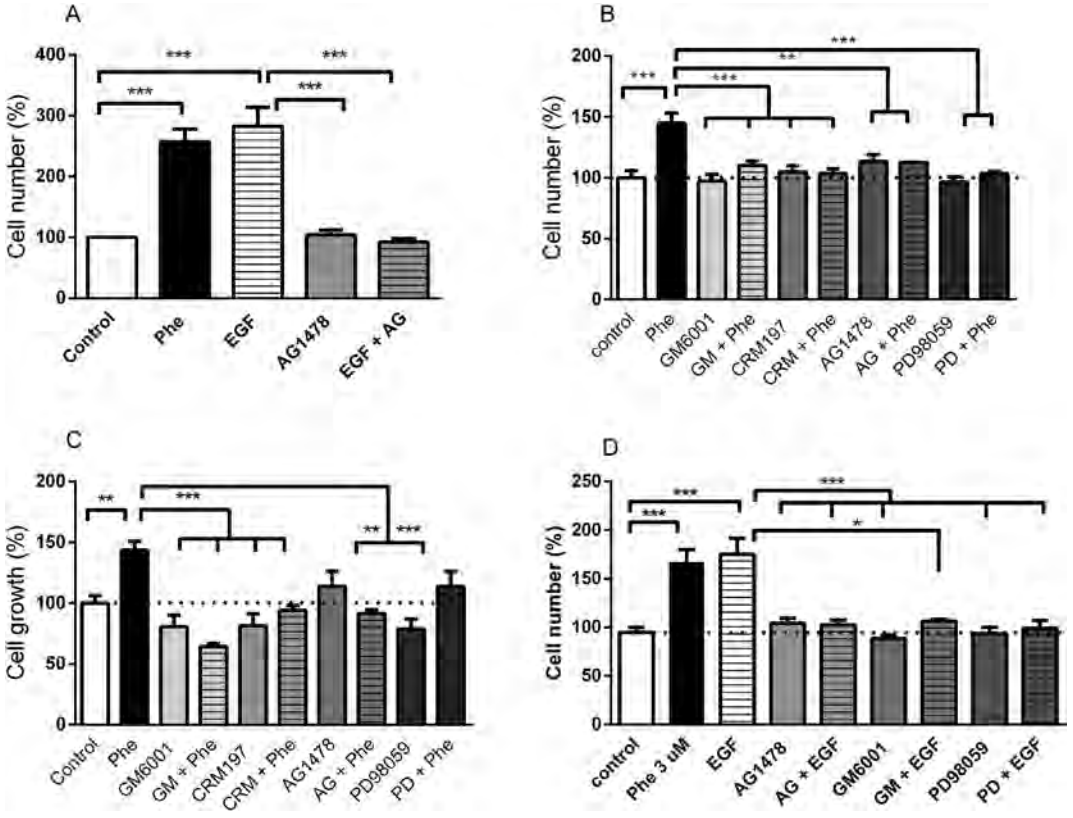

Fig. 4. The BPH cell proliferative effect of phenylephrine depends on the activation of EGF receptors. A) Hyperplastic stromal cells in culture were treated with 3 μM phenylephrine (Phe) or 100 ng/mL EGF for 48 h in the absence (control, white bar) or presence of the EGF receptor tyrosine kinase inhibitor AG1478 5 μM ***P < 0.001 Phe and EGF vs. control; AG1478 and EGF + AG vs. EGF (one way ANOVA followed by Dunnett's multiple comparisons test).
B and C) Hyperplastic stromal cells were treated with 3 μM phenylephrine (black bar) for 48 h in the absence (control, white bar) or presence of the following inhibitors of EGF receptor signaling: GM = GM6001 10 μM; CRM = CRM197 200 ng/mL; AG = AG1478 5 μM; PD = PD98059 1 μM. Cell proliferation was accessed by cell counting using Trypan Blue exclusion dye (B) and MTT assays (C). D. The EGF-mediated cell growth (100 ng/mL) is fully inhibited by AG1478, GM6001 and PD98059. The inhibitors alone did not alter basal cell proliferation (P > 0.05). Data were expressed as mean and S.E.M. of 3 experiments (performed in duplicate (A) or quadruplicate (B)), or 4 experiments performed in quadruplicate (C, D). B and C: **P < 0.01 and ***P < 0.001 vs. Phe; D: *P < 0.05 and ***P < 0.001 vs. control or EGF (one way ANOVA followed by Dunnett's multiple comparisons test).

INFORME DE LABORES 2019

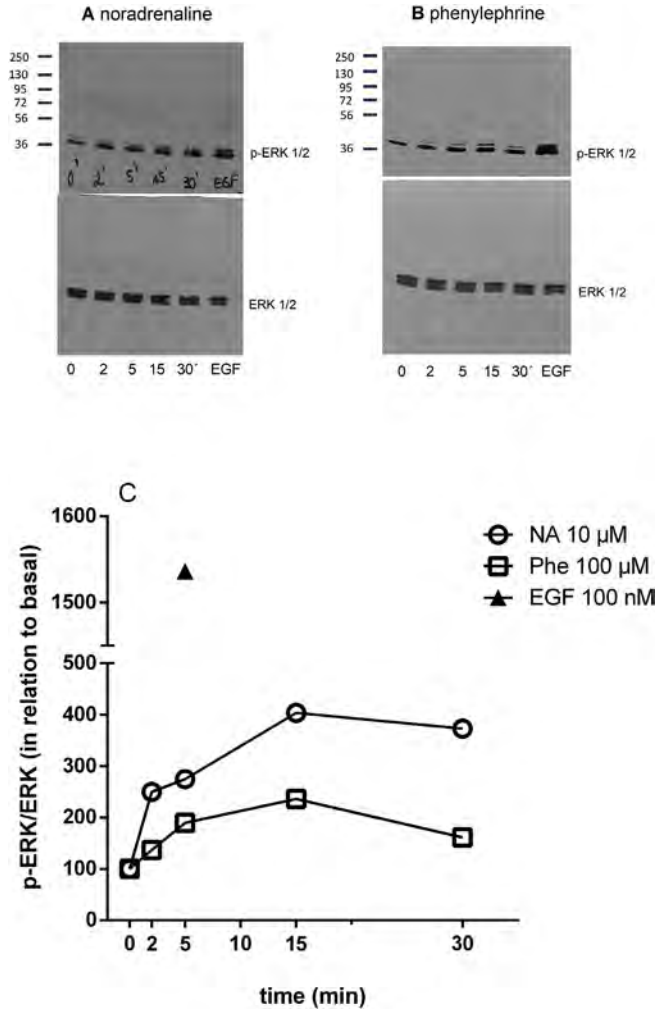

Fig. 5. Time-dependent activation of ERK 1/2 by phenylephrine and noradrenaline in hyperplastic stromal cells obtained from BPH patients (full-length representative blots). Cells were treated with 100 µM phenylephrine (Phe; A), 10 µM noradrenaline (NA) in the presence of 1 µM propranolol (B), for the indicated times or 100 ng/mL EGF (5 min, A-C). C. Densitometric analysis. Data were expressed as mean of 2 individual experiments.

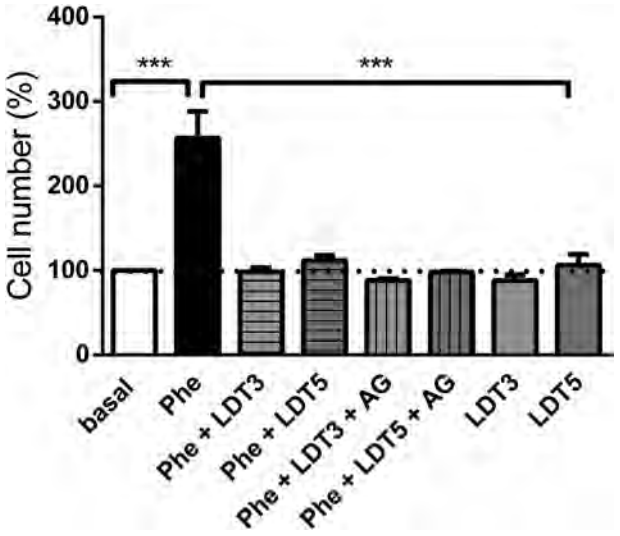

Fig. 6. The BPH cell proliferative effect of phenylephrine is completely inhibited by α_1-adrenoceptor antagonists (LDT3 and LDT5) or AG1478, an EGF receptor tyrosine kinase inhibitor, alone or in association. The co-incubation of AG1478 (5 µM) with the α_1-adrenoceptor antagonists did not potentiate the inhibitory effect of LDT3 and LDT5. Phe = phenylephrine. Data were expressed as mean and S.E.M. of 2 individual experiments performed in triplicate. ***P < 0.001 all conditions vs. Phe (one way ANOVA followed by Dunnett's multiple comparisons test).

cells from human prostate yields a small quantity of material. The cell immortalization frequently causes the loss of cell characteristics, making the screening of immortalized cell clones for lines that keep the phenotypic characteristics needed. For instance, immortalized human prostate stromal cells show an increased expression of α_{1B}-adrenoceptors which is not observed in human prostate or primary cultured cells [37]. Therefore we used primary cell culture obtained from BPH patients (*i.e.*, non-transformed cells). In our model, cultured cells stained positively for vimentin, and negatively for the epithelial cell marker cytokeratin, indicating the predominance of stromal cells.

The proposed ratio of α_{1A}:α_{1B}:α_{1D}-adrenoceptors mRNA in normal human prostate is approximately 63:6:31%, respectively [6]. In support to these data real time RT-PCR assays corroborate the predominance of α_{1A}- and α_{1D}-adrenoceptors mRNA [5]. Moreover, an increased expression of α_{1A}- and α_{1D}-adrenoceptors mRNA has been reported in BPH, and the α_{1D}-adrenoceptor mRNA has a more pronounced increased expression (as high as three times) [5,6]. Therefore these upregulated receptors are supposed to participate in the pathophysiology of BPH. However, most, if not all, commercially available antibodies against each subtype of α_1-adrenoceptor lacks selectivity, which limits the quantification of the protein at cellular level [38], and the identification of functional α_1-adrenoceptor subtypes relies on the use of selective drugs.

Our data showed that BPH stromal cells express functional α_1-adrenoceptors since phenylephrine, a selective α_1-adrenoceptor agonist, activated the canonical signaling pathway involving the increase of $[Ca^{2+}]_I$. Similar data were obtained using the endogenous non-selective adrenoceptor agonist noradrenaline, when tested in the presence of propranolol for blocking its β–adrenoceptor effects. Moreover, functional data suggest that α_{1D}-adrenoceptor is involved in the BPH cell proliferative effect of phenylephrine since BMY7378, a selective α_{1D}-adrenoceptor antagonist, blocked the agonist effect [28].

EGF receptor is a membrane-bound glycoprotein expressed in normal and hyperplastic human prostate [39,40] including stromal cells [27,35, and present data]. One of the proposed mechanisms leading to EGF receptor transactivation by GPCR includes the action of metalloproteinases promoting the shedding of members of EGF family such as HB-EGF, and consequently the binding to its cognate receptor [15,18,20]. As a consequence, metalloproteinase inhibition is reported as a strategy to interrupt EGF receptor transactivation. Here we showed that inhibition of metalloproteinase prevented BPH cell growth mediated by phenylephrine, which could suggest that the activation of α_1-adrenoceptor induces EGF receptor transactivation. In support of these data it was previously shown in rat lacrimal gland epithelial cells that α_{1D}-adrenoceptor mediates the shedding of EGF and EGF receptor activation [41].

In our model EGF induced stromal cell proliferation. As shown by Duque and colleagues [27], both HB-EGF and EGF (100 ng/mL) induce a similar mitogenic effect upon human prostate stromal cell suggesting a role of these agonists in BPH. Moreover, stromal cells express HB-EGF mRNA and the HB-EGF inhibitor CRM197 inhibits in a concentration-dependent manner the stromal cell growth [27].

There is evidence that a naturally occurring human α_{1A}-adrenoceptor genetic variant is constitutively coupled to EGFR transactivation [23]. In support of our hypothesis that α_1-adrenoceptors might induce transactivation of EGF receptor in BPH cells, the HB-EGF inhibitor CRM197, as well as the EGF tyrosine kinase receptor inhibitor AG1478, prevented hyperplastic cell growth induced by phenylephrine. Of note, the concentration of AG1478 used (5 µM) fully inhibited the

phenylephrine- and the EGF-induced cell proliferation. As ERK 1/2 activation is important for cell proliferation, and it may be activated by EGF receptor signaling, we investigated the effect of the MEK inhibitor PD98059, which also inhibited the proliferative effect of phenylephrine. Accordingly, in Western blotting assays, besides EGF (positive control), phenylephrine (and noradrenaline) also stimulated ERK 1/2 phosphorylation corroborating functional data. Therefore, our results suggest that α_1-adrenoceptors (most probably α_{1D}-subtype) transactivate EGF receptors in stromal cells from BPH patients leading to cell proliferation. However, present data do not rule out that the canonical signaling of α_1-adrenoceptor (*i.e.*, Gq canonical signaling) could also activate ERK pathway. On the other hand, as the inhibition of EGF receptor signaling did not reduce cell proliferation in the absence of phenylephrine, we could suggest that α_1-adrenoceptor-mediated EGF receptor transactivation is mainly agonist-dependent, rather than constitutively active as previously shown in cardiomyoblasts [42].

Different sets of evidence obtained by others indicate that transactivation of EGF receptors is involved in α_1-adrenoceptor signaling. For instance, it has been shown that α_{1D}-adrenoceptor activation induces the shedding of biologically active EGF and subsequent EGF receptor transactivation, and an EGF neutralizing antibody reduces phenylephrine-induced ERK activation in rat lacrimal gland [41]. Moreover, α_1-adrenoceptor activation induces ERK 1/2 activity in rat aorta myocytes (mainly α_{1D}-adrenoceptor type) [19], and in human epithelial prostatic cells where ERK 1/2 activity was related to cell volume regulation [43]. In good accordance with our data, the metalloproteinase inhibitor GM6001 [41] and the EGF receptor inhibitor AG1478 [19] blocked ERK 1/2 activation in response to phenylephrine linking α_1-adrenoceptor to EGF receptor transactivation. On the other hand, the β-adrenoceptor-mediated EGF receptor transactivation may involve (COS-7) or not (brown adipocytes) ERK 1/2 pathway [44,45]. Therefore ERK 1/2 activation during EGF receptor transactivation depends both on GPCR and cell type.

It is noteworthy that the co-incubation of EGF receptor inhibitor AG1478 with the α_{1A}-/α_{1D}-adrenoceptor antagonists LDT3 or LDT5 resulted in full inhibition of cell proliferation, which was similar to the inhibition promoted by each drug alone. A putative nonspecific inhibition of androgen receptors by these α_1 adrenoceptor antagonists was ruled out by binding assays. Moreover, as previously shown by our group or by others, the α_{1D}-adrenoceptor selective antagonists BMY7378 and naftopidil also fully inhibited the proliferative effect of phenylephrine in BPH cells [28,30]. However, in these models tamsulosin, a benzenesulfonamide derivative, showed no effect [28,30]. Furthermore, tamsulosin alone did not inhibit the increase of volume of the cell line BPH-1 in response to phenylephrine [43]. In common, BMY7378, naftopidil, LDT3 and LDT5 are α_{1D}-adrenoceptors antagonists that share the *N*-phenylpiperazine moiety which could shape some inhibitory functional selectivity upon BPH cell proliferation, and therefore other experiments would be welcome. Patients' adherence to current pharmacotherapy is low, a fact that favors BPH progression [46] and stimulates the search for new drugs. Understanding the mechanisms involved in prostate cell proliferation may help the development of new drugs.

In conclusion, our findings demonstrate that α_1-adrenoceptor activation in human hyperplastic prostate cells induces canonical and non-canonical signaling. The α_1-adrenoceptor non-canonical signaling involved in mitogenesis of BPH cells depends on EGF receptor transactivation. This mechanism could contribute to prostate enlargement and to the development of LUTS/BPH, and therefore our data give new insight into the physiopathology of BPH. We therefore propose that blockage of this transactivation cascade could be a putative non-hormonal pharmacological strategy to reduce concomitantly LUTS and BPH progression.

Author contributions

Conducted experiments: JBNV, RAH, LACB.

Contributed with reagents or cell culture: LASR, LEN, EOB, JAGS.

Participated in research design and coordinated experiments: CLMS, JAGS.

Performed data analysis, discussion, revised the manuscript: JBNV, RAH, PRF, FN, JAGS, CLMS.

Wrote the manuscript with important contributions by all authors: CLMS. All authors read and approved the final version of the manuscript.

Declaration of competing interest

None.

Abstract

A method to study desensitization and recovery of crayfish photoreceptors is presented. We performed intracellular electrical recordings of photoreceptor cells in isolated eyestalks using the discontinuous single electrode-switched voltage-clamp configuration. First, with a razor blade we made an opening in the dorsal cornea to get access to the retina. Thereafter, we inserted a glass electrode through the opening, and penetrated a cell as reported by the recording of a negative potential. Membrane potential was clamped at the photoreceptor's resting potential and a light-pulse was applied to activate currents. Finally, the two light-flash protocol was employed to measure current desensitization and recovery. The first light-flash triggers, after a lag period, the transduction ionic current, which after reaching a peak amplitude decays towards a desensitized state; the second flash, applied at varying time intervals, assesses the state of the light-activated conductance. To characterize the light-elicited current, three parameters were measured: 1) latency (the time elapsed between light flash delivery and the moment in which current achieves 10% of its maximum value); 2) peak current; and 3) desensitization time constant (exponential time constant of the current decay phase). All parameters are affected by the first pulse.

To quantify recovery from desensitization, the ratio p2/p1 was employed versus time between pulses. p1 is the peak current evoked by the first light-pulse, and p2 is the peak current evoked by the second pulse. These data were fitted to a sum of exponential functions. Finally, these measurements were carried out as function of circadian time.

Introduction

In order to be perceived as a visual stimulus, light reaching the eyes must be transduced into an electrical signal. Hence, in all visual organisms, light triggers a transduction ion-current, which in turn produces a change in the membrane potential of photoreceptor cells, the so-called receptor potential. Due to this, the light sensitivity of the eye primarily depends on the state of the light activated conductance, which can be either available to be activated or desensitized.

In crayfish photoreceptors, light triggers a slow, transient, ionic current[1]. Upon illumination, the transduction current arises after a lag or latency before reaching its maximum; thereafter it decays, as the transduction channels fall into a desensitized state in which they are unresponsive to further light stimulus[2]. That is, light, in addition to activating the transduction current responsible of vision, also induces a transient decrement of the sensitivity of photoreceptor cells. Desensitization may represent a general protective mechanism against overexposure to an adequate stimulus. The eye's sensitivity to light is recovered as the transduction conductance recovers from desensitization.

Intracellular recording is a useful technique for measuring electrical activity of excitable cells[3,4,5,6,7,8]. Although intracellular recording has become less frequent with the advent of the patch-clamp technique[9], it is still a convenient approach when cells are either difficult to isolate, or present a geometry that makes the formation of the patch-clamping giga-seals difficult (*i.e.*, seals or tight-contacts between the patch electrode and membranes with electrical resistance of the order of 10^9ohms). Examples of the latter are sperm cells[10] and the photoreceptor cells herein studied. In our experience, *Procambarus clarkii* photoreceptors are difficult to isolate and keep in primary culture; additionally, they are thin rods that make giga-seal formation difficult to achieve. In intracellular recordings, a sharp electrode is advanced into a cell that is kept in place by the surrounding tissue. The electrode is chopped by the high-speed switching circuitry of the amplifier, so current is sampled between voltage pulses. This mode is known as discontinuous single-electrode voltage clamp (dSEVC mode)[11]. The high resistance (small opening) of the electrode hinders the diffusional exchange between the cell and the pipette solutions, yielding a minimal disturbance of the intracellular milieu[3]. A potential drawback of this technique is that electrode insertion may produce a non-selective leak current; therefore, care must be taken to avoid recording from cells where the size of the leak current may interfere with the intended measurements[4,12].

Herein, we use isolated crayfish eyestalks to assess desensitization and recovery of the light-activated ion conductance by performing intracellular electrical recordings of photoreceptor cells under voltage clamp conditions.

Protocol

NOTE: The experiments comply with the Laws of Animal Protection of Mexico.

1. Experimental Setup

1. General connections
    1. Connect the amplifier to a suitable computer through an analog-to-digital converter and use an oscilloscope to monitor the experiment (**Figure 1**).
    2. Connect the photostimulator to the A/D converted.

2. Recording chamber
    1. Place the recording chamber on top of an anti-vibration table and locate it inside a Faraday cage.
    NOTE: This prevents mechanical vibration and electrical noise that may affect the recording. Our Faraday cage was made of darkened wire mesh. A homemade, 2 mL, acrylic recording chamber is used (**Figure 2**).
    2. Prepare the bath solution to keep the preparation alive[13]: 205 mM NaCl; 5 mM KCl; 2 mM $MgSO_4$; 13 mM $CaCl_2$; 5 mM Hepes-NaOH, pH 7.3.
    NOTE: Solution does not include dextrose or any bubbling by 95% O_2, 5% CO_2 mixture because the experimental procedure is short enough to detect damage by the electrical recording (see step 4.2.3 for completeness).

3. Electrodes
    1. Use a chloride-coated silver-wire electrode as the reference electrode
    NOTE: Silver chloride coating is necessary to allow the electrode reaction: $AgCl(s) + e^- \leftrightarrow Ag(s) + Cl^-$.
    2. Sand a silver wire (thickness ~ 1 mm, length ~ 10 cm) with a fine grade emery paper in order to clean its surface.
    3. Rinse the silver wire with distilled water.
    4. Immerse the clean silver-wire in a 4-6% sodium hypochlorite solution (NaClO) until it appears dark (approximately 20 min).
    5. Use thin glass pipettes filled with an electrolyte solution (2.7 M KCl) as the intracellular electrode.
    6. Pull a glass capillary tube (internal diameter ≈ 1 mm) with a micro-pipette puller to obtain a thin tip with a small opening (0.01-0.1 µm)[14].
    7. Fill the pulled capillary glass with a 2.7 M KCl solution. First fill it by capillarity (immerse the pipette tip into the 2.7 M KCl solution) and then fill the half of the pipette with a fine injection needle. If necessary, tap the electrode pipette to eliminate air bubbles.
    8. Connect the electrode to its holder. Connect the holder to the amplifier headstage with the amplifier. Position the electrode-holder-headstage with a stable 3-D micromanipulator. Lower the electrode until bath solution covers its tip.
    NOTE: The electrode must have a vertical orientation

4. Select the Bridge Mode of the amplifier (in the Mode section of the amplifier, press the Bridge button) and measure the electrode resistance. Make sure that the resistance is about 50 MΩ[11].
NOTE: This electrode size allows a good-quality electrical recording with limited damage to the cell.
5. Null the offset current and compensate capacitive transients using the Holding Position button in the section Voltage Clamp of the amplifier, and the Capacitance Neutralization button in Microelectrode 1 section of the amplifier.
6. Superfusion system
    1. Pour the bath solution (step 1.2.2) into a suitable receptacle (a 250 mL serum bottle) and connect it to an irrigation tubing set (3.2 mm of internal diameter), thus connecting the recording chamber. Use a gravity driven superfusion system. Regulate the flow rate to ~ 0.5 mL/s.
    2. Connect the chamber to a suction device. Regulate the solution suction system in such a way that the total volume of the recording chamber does not vary. Use a vacuum pump for suction.
    NOTE: A constant volume in the recording chamber is important to keep stray capacitances constant throughout the experiment.

2. Biological Material

Note: Use adult crayfishes *P. clarkii* (7-10 cm long) in the intermolt stage of indistinct sex.

1. Circadian time
    1. One month prior to the experiments, maintain 100 crayfishes under a 12-h light/12-h dark cycle[15] (white light, 2.4 kW/m^2).
    NOTE: One month is sufficient time to synchronize the crayfish population.
    2. Determine the circadian time of the crayfish population by assessing the amplitude of electroretinograms of five randomly chosen animals[15].
    NOTE: 0 h circadian time (CT 0) indicates the beginning of a subjective day, *i.e.*, time during which an organism is normally active[16,17,18,19] (**Figure 3**). The crayfish is a nocturnal animal, so under a 12-h light/12-h dark cycle, it is active during the dark phase.

2. Eyestalk isolation procedure
    1. At the desired circadian time, anesthetize a selected crayfish by immersion in tap water at 0-4 °C, for 15 min.
    2. By means of a fine scissor, detach the eyestalk from the base.
    3. Access the retina using a razor blade to make an opening (~ 1-mm^2) in the dorsal cornea.

4. Place the eyestalk in the center of the recording chamber (the hole covered with silicone) with the access opening to the retina on the top of the chamber.

3. Keep the eyestalk under constant darkness for 20 min.
NOTE: 20 min is sufficient time for the photoreceptor cell to be fully dark adapted.

3. Photoreceptor Impaling

1. Put the microelectrode and the eyestalk's longitudinal axis parallel in such a way that the microelectrode is centered for access to the retina. Use a stereoscopic microscope (10X) to place the devices in the correct configuration.
2. Monitor the voltage difference between the reference and recording electrodes by selecting the Bridge Mode[11] of the amplifier.
3. Lower the electrode into the bath and thereafter place it right over the retina.
4. Move away the microscope and position the photostimulator lamp parallel to the eyestalk's longitudinal axis.
NOTE: Distance between lamp and superfusion chamber is approximately 15 cm.
5. Slowly lower the microelectrode until a sudden voltage drop is detected.
NOTE: A voltage drop of around −50 mV indicates the impalement of a healthy photoreceptor cell.
6. Deliver a test light-flash (white light, 7.2 kW/m^2, 10 µs duration) to record the photoreceptor's receptor potential.
NOTE: The photoreceptor's receptor potential is a depolarizing potential of 10-15 mV amplitude and 300 ms duration (**Figure 4**).

4. Electrical Recording

1. Ensure that the photoreceptor cells are totally adapted to dark conditions (see step 2.3).
    1. Deliver a test-light flash every 2 min. Automate the time between flashes by choosing an adequate value (120 s) of "time between episodes" in the data acquisition software.
    NOTE: 2 min is the necessary time to allow the total recovery of the currents underlying the photoreceptor's electrical response.
    2. Monitor the resting membrane potential, as well as the amplitude and duration of the receptor potential. Assume that the photoreceptor is completely adapted once the membrane potential, amplitude, and duration of the receptor potential remain unchanged. Eyestalks previously kept under constant darkness for 20 min (step 2.3) complete their adaptation in approximately 5 min.
    3. Stop stimulating the cell 2 min before recording the light-elicited current.

2. Current recording
    1. Clamp the voltage at the measured resting membrane potential value of the cell by selecting "Holding amplitude" in the data acquisition software (in Waveform on the Analog Output Channel section).
    2. Select the dSEVC mode of the amplifier. In the Mode section of the amplifier, select the SEVC button and switch the lever to the Discont SEVC position.
    3. Set the switching rate to 500-1,000 Hz (by using the Rate Adjust button of the amplifier), as determined by the speed of the electrode[11].
    4. Deliver a light-flash, and observe the evoked ion influx.
    NOTE: This is the light-elicited or transduction current (**Figure 5**).
    5. Return to the Bridge mode on the amplifier and record a receptor potential by sending a light flash (see section 3). Make sure that the photoreceptor cell is totally adapted to dark conditions. Measure the receptor potential characteristics (amplitude and duration) and compare with the first measurements. Assume that the impaled photoreceptor cell is a healthy cell if they have the same characteristics.
    NOTE: After eyestalk ablation, biological preparation is viable during the following 2 h.

3. Two pulse protocol: Measure the recovery from desensitization with a two light-flash protocol.
NOTE: The two light-flash protocol is similar to the standard two-pulse voltage protocol used to measure recovery from inactivation of voltage-gated channels[20]. The first light-flash causes a temporary change in the sensitivity of the photoreceptor cell and the second flash evaluates the state of the light-activated conductance.
    1. Deliver a pair of light pulses. Apply the second flash after a desired time interval (from 300 ms to 2 min).
    2. Digitize the currents at 10 KHz sampling with the data acquisition software and save the data for off-line analysis[11].
    NOTE: A table with the configuration values of the software is included as supplementary material.

5. Data Analysis

1. Kinetics of the light-elicited current
    1. Measure three current parameters: activation latency L, the time elapsed from the light-flash delivery until the current attains 10% of its maximal amplitude (**Figure 5**); peak or maximal current amplitude I_p; and desensitization time constant T. Measure the desensitization time constant (T) by fitting the current decay phase to:
    $$i(t) = -Ae^{\frac{-t}{T}}$$
    where, A = -I(t=0) is a positive constant (**Figure 5**).

2. Desensitization and recovery
Note: Recovery from desensitization was assessed as the ratio p_2/p_1, where p_1 is the relevant parameter (either L, I_p, or T) of the control current, and p_2 is the corresponding parameter of the second test-current.
    1. Plot p_2/p_1 (either L, I_p, or T) as a function of time between pulses.
    2. Depending on the parameter, fit the points of each plot to:

$$\frac{p_2}{p_1} = \sum_{1}^{n} 1 - e^{\frac{-t}{\tau_n}}$$

or to:

$$\frac{p_2}{p_1} = \sum_{1}^{n} 1 + A_n e^{\frac{-t}{\tau_n}}$$

3. Use an appropriate statistical test to determine the number of exponential terms required to fit the experimental data.

Representative Results

First, a representative receptor potential of crayfish photoreceptor cells is obtained (**Figure 4**). Afterwards, a test light-flash was applied to trigger the light transduction current (**Figure 5**). The cationic transduction current[1] activates after a lag, reaching a maximal and thereafter slowly drops into an absorbing desensitized state from which it slowly recovers.

It is reasonable to suppose that the long latency L (tens of milliseconds) of the light-elicited current depends on the biochemical events triggered by light, which involve G-protein pathways. The amplitude of the peak current I_p depends on the fraction of channels available to be opened, and the relative rates of current activation and inactivation. The latter is assessed by the decay time constant T.

On the other hand, the L recovery should be related to the rate of recovery of the biochemical phototransduction cascade; I_p recovery depends both, on the intrinsic conformational changes of the proteins responsible for the ion conductance, and on the rate of recovery of the biochemical phototransduction cascade. The latter could also be related to the recovery of T. Furthermore, the parallel variation of L and T suggest that a common biochemical factor (or factors; *e.g.*, the phosphorylation state of the channel) can affect both parameters[1].

A two-flash protocol (**Figure 6**) was applied subsequently to determine the kinetics of recovery from desensitization (**Figure 7**) at different moments in the circadian cycle (**Figure 8**).

Discussion

The crayfish has proven to be an excellent model due to its ability to survive under non-natural conditions. There is easy access to *in vivo* and *in vitro* electrophysiological analyses. In addition, crustaceans are a favorable group for neurobiological research in the field of comparative chronobiology[21].

In this paper, the study of desensitization and recovery of the light-activated transduction-current of crayfish photoreceptor cells is shown using the intracellular recording technique. However, we believe that the same technique could be adapted to other invertebrate visual systems as long as it is possible to access photoreceptor cells.

To obtain acceptable experimental results, it is important to consider some critical steps in the protocol, including eliminating electrical noise by grounding all equipment, building an electrode with a sufficiently fine tip, and ensuring that the photoreceptor cell is completely dark-adapted before the two-pulse protocol begins.

Despite the limitations of intracellular recording such as the damage of membrane, it is possible to go further and obtain detailed information about the biophysical mechanism underlying crayfish (or another animal) photoreceptor electrical signal. As in other invertebrate photoreceptors, in crayfish photoreceptors, light triggers a graded depolarization, or receptor potential, produced by the activation of a cationic conductance. The light-activated conductance begins after a lag or latency, and after reaching its maximal amplitude, it slowly drops following an exponential time course, as the channels enter an absorbing desensitized state.

The kinetics of recovery from desensitization of the light-elicited ion conductance of crayfish were obtained using a two-light flash protocol (similar to the standard two-voltage pulse protocol used to study recovery from inactivation of voltage-gated channels)[20]. Interestingly, and in contrast to the well-known case of voltage-gated channels, not only the peak amplitude, but also all the current parameters (I_p, L, T) change after the first light stimulus, recovering with characteristic exponential time courses to the original, first flash values, as reported elsewhere[20]. This variation of all the parameters that characterize the current indicates the participation of second messengers in the visual transduction system of crayfish[1,2,22,23,24].

Additionally, and interestingly, as **Figure 8** shows, recovery of L, I_p, and T depends on the circadian time at which experiments are realized. Further studies are needed to determine the molecular basis of this phenomenon. Of course, it is possible to obtain similar information using another technique, such as patch clamp. However, the intracellular milieu can be greatly disturbed in other techniques, and this could be critical, if, for example, internal elements like proteins, amino acids, nucleotides, among many others, play a relevant role in the electrical signal generation or in the interaction with hormones or neuromodulators.

Disclosures

We have nothing to disclose.

Heterologous calcium-dependent inactivation of Orai1 by neighboring TRPV1 channels modulates cell migration and wound healing

Carlos Ernesto Bastián-Eugenio[1], Arlette Bohórquez-Hernández[1], Jonathan Pacheco[1], Alicia Sampieri[1], Alexander Asanov[2], Jose Pablo Ocelotl-Oviedo[3], Adán Guerrero[4], Alberto Darszon[3] & Luis Vaca[1]

Store-operated calcium entry (SOCE) is an essential calcium influx mechanism in animal cells. One of the most important auto regulatory control systems involves calcium-dependent inactivation (CDI) of the Orai channel, which prevents excessive calcium influx. In the present study we analyze the role of two channels in the induction of CDI on Orai1. Here we show that calcium entering through freely diffusing TRPV1 channels induce strong CDI on Orai1 while calcium entering through $P2X_4$ channel does not. TRPV1 can induce CDI on Orai1 because both channels were found in close proximity in the cell membrane. This was not observed with $P2X_4$ channels. To our knowledge, this is the first study demonstrating that calcium arising from different channels may contribute to the modulation of Orai1 through CDI in freely diffusing single channels of living cells. Our results highlight the role of TRPV1-mediated CDI on Orai1 in cell migration and wound healing.

The calcium ion (Ca^{2+}) is a second messenger with a key role in numerous cellular processes[1]. Cells have developed many mechanisms to regulate this ion[2]. Store-operated calcium entry (SOCE) is the principal mechanism for calcium mobilization in non-excitable cells[3,4]. The prototypical store-operated calcium channel is the Ca^{2+} release-activated Ca^{2+} (CRAC) channel[5,6]. The essential components of CRAC are the endoplasmic reticulum (ER) Ca^{2+} sensor STIM1[7,8] and the plasma membrane (PM) channel Orai[9]. In general, activation of inositol 1,4,5-triphosphate (IP_3) receptors on the ER produces a rapid and transient release of Ca^{2+} from ER store. The resulting decrease of the Ca^{2+} concentration inside the ER is sensed by the EF-hand motif of STIM1, which then translocates to the PM, associating to Orai and inducing channel activation.

Orai activity is regulated through a negative feedback mechanism that maintains intracellular Ca^{2+} homeostasis and prevents excessive Ca^{2+} influx. Such a mechanism is known as Ca^{2+}-dependent inactivation (CDI).

CDI consists of slow CDI (SCDI) and fast CDI (FCDI), which have different kinetics and sites of action. SCDI occurs gradually in tens of seconds after channel activation and has been reported to occur by global increases in cytosolic calcium concentrations[10]. The most important regulator of SCDI is the SOCE-associated regulatory factor (SARAF)[11]. Moreover, SCDI can be regulated by other factor such as caveolin, E-syt1, septin4, and $PI(4,5)P_2$[12,13].

FCDI take place within ~10–100 ms after channel activation and is controlled by Ca^{2+} binding to a site located ~8 nm from the channel pore[14,15]. FCDI is modulated by various factors, including the STIM1-Orai1 expression ratio[16], an amino acid region negatively charged in STIM1 (residues 475–483)[17–19], the intracellular loop II–III of Orai1[20], the N-terminus of Orai1 (residues 68–91)[17,21], and also probably the first 63 amino acids from Orai1[22]. Most interestingly, a single amino acid mutation alters FCDI in Orai1 channels rendering the channel CDI insensitive[21].

To our knowledge, all the studies carried out to this date to understand and explore CDI have been conducted by artificially increasing intracellular Ca^{2+} via the patch clamp pipette or by measuring CDI with normal and reduced extracellular calcium concentrations, which reflects CDI induced by Ca^{2+} entering through the Orai channel pore (homologous CDI). Less studied are physiological sources of Ca^{2+}, such as the contribution of other channels to CDI in Orai.

In the present study, we have explored other sources of Ca^{2+} arising from different channels that may play a role in Orai's CDI. We have found that Ca^{2+} entering the cell through TRPV1 channels induce strong CDI in Orai1, while Ca^{2+} entering through $P2X_4$ purinergic channels does not. Super resolution studies indicate that Orai1 and TRPV1 are associated and move in close proximity to each other at the PM, while $P2X_4$ and Orai1 do not. These results were confirmed by co-immunoprecipitation (CoIP) and Förster resonance energy transfer (FRET) studies between Orai1-TRPV1 and Orai1-$P2X_4$.

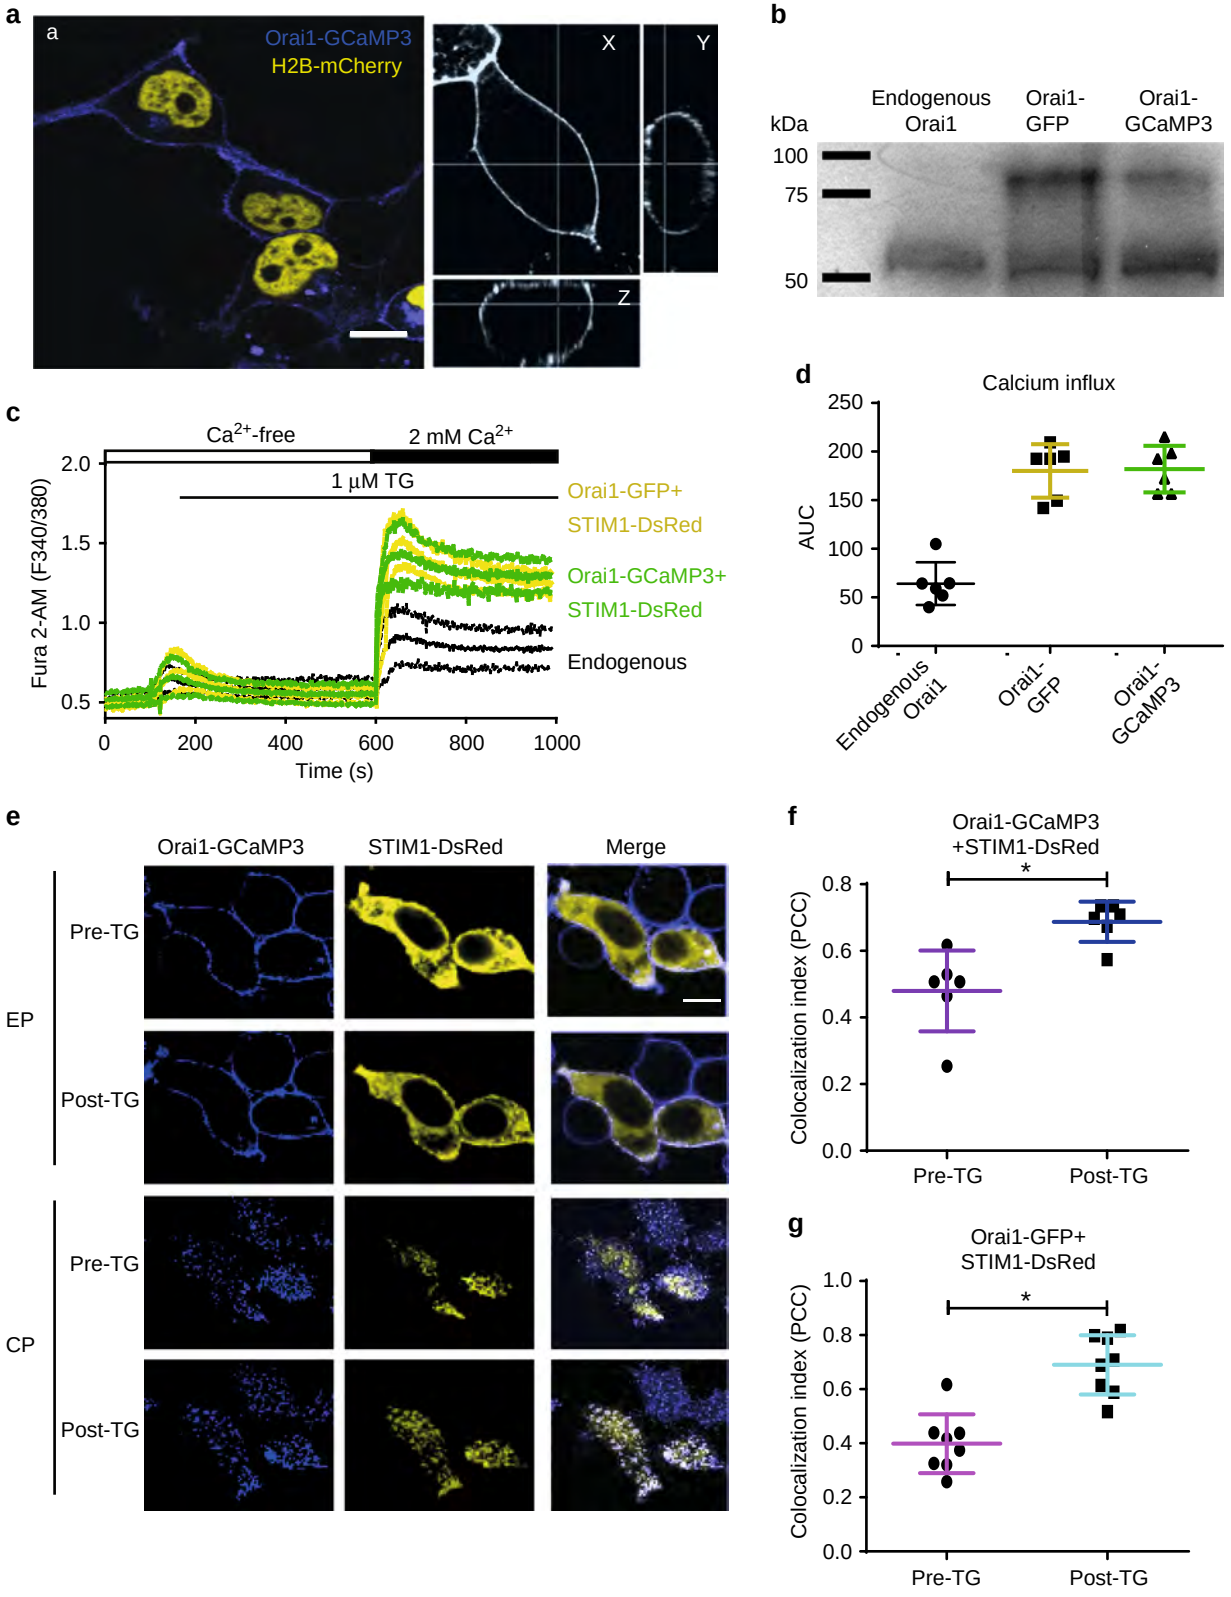
All the results presented here strongly suggest that a close association between TRPV1 and Orai1 results in an elevated Ca^{2+} microenvironment near the Orai1 pore when TRPV1 channels are activated, which enhances CDI in Orai1. Because $P2X_4$ and Orai1 are not found in close proximity at the PM, Ca^{2+} entering $P2X_4$ channels do not induce CDI in Orai1, in spite the fact that Ca^{2+} entering through $P2X_4$ channels contribute to increments in cytosolic Ca^{2+} concentrations.

These results have important physiological implications in the modulation of calcium influx in cells where TRPV1 and Orai1 channels coexist, such as astrocytes. We show that TRPV1 is an important modulator of Orai1 channel activity in cortical astrocytes by controlling CDI in this channel and thus reducing the amount of Ca^{2+} entering to the cell when TRPV1 and Orai1 are simultaneously or sequentially activated. This heterologous modulation of CDI plays a role in controlling cell migration and wound healing mediated by astrocytes.

Results

Engineering of Orai1-GCaMP3 to characterize CDI. In an attempt to identify how Orai1 may sense changes of Ca^{2+} in its vicinity, we engineered a fusion protein consisting of the green genetically encoded calcium indicator (GCaMP3) fused to the amino terminus of Orai1 channel (Orai1-GCaMP3). We use the red calcium indicator (R-GECO) to simultaneously measure changes in global calcium in the cytosol and compare it to local calcium changes reported by the fusion protein Orai1-GCaMP3, which would presumably report only calcium changes near the channel pore from Orai1.

Firstly, we characterize Orai1-GCaMP3 to determine if the fusion protein behaves like a wild type Orai1 channel. Orai1-GCaMP3 is found primarily at the PM, similarly to Orai1 alone or Orai1-GFP used as controls (Fig. 1a). The expression of the fusion protein was identified also by western blot (Fig. 1b, for full-length blot see Supplementary Fig. 1). As expected, cells overexpressing Orai1-GCaMP3 or Orai1-GFP showed enhanced SOCE (Fig. 1c, d), indicating that the functionality of Orai1-GCaMP3 is indistinguishable from that of Orai1-GFP. This was clear when measuring the area under the curve (AUC) for calcium entry (Fig. 1d), but also with the peak increments in Fura-2 fluorescence from the same data (endogenous 0.43 ± 0.15, Orai1-GCaMP3 0.92 ± 0.18, and Orai1-GFP 0.99 ± 0.16, Fig. 1c).



Furthermore, Orai1-GCaMP3 forms regular puncta with STIM1 when internal calcium stores are depleted with thapsigargin (TG) (Fig. 1e–g). These results indicate that the function of Orai1 is unaltered by fusing the GCaMP3 calcium indicator.

We characterize further the calcium changes sensed by Orai1-GCaMP3 or by R-GECO present in the cytosol as a soluble protein. We proceeded to explore the ability of Orai1-GCaMP3 to sense calcium increments when other channels that permeate calcium are activated. We explored several channels and found that Orai1-GCaMP3 senses calcium arising from the activation of TRPV1 channel (Fig. 2a, b) but not from the $P2X_4$ purinergic receptor (Fig. 2c, d). Most interestingly, a PM targeted calcium sensor (Lck-GCaMP5)[23] detects calcium increments derived from the activation of both, TRPV1 and $P2X_4$ channels (Supplementary Fig. 2). These results suggest that, even though both fusion proteins (Orai1-GCaMP3 and Lck-GCaMP5) are located at the PM, they may be contained within different microdomains conferring them differential sensitivity to calcium increments arising from different sources.

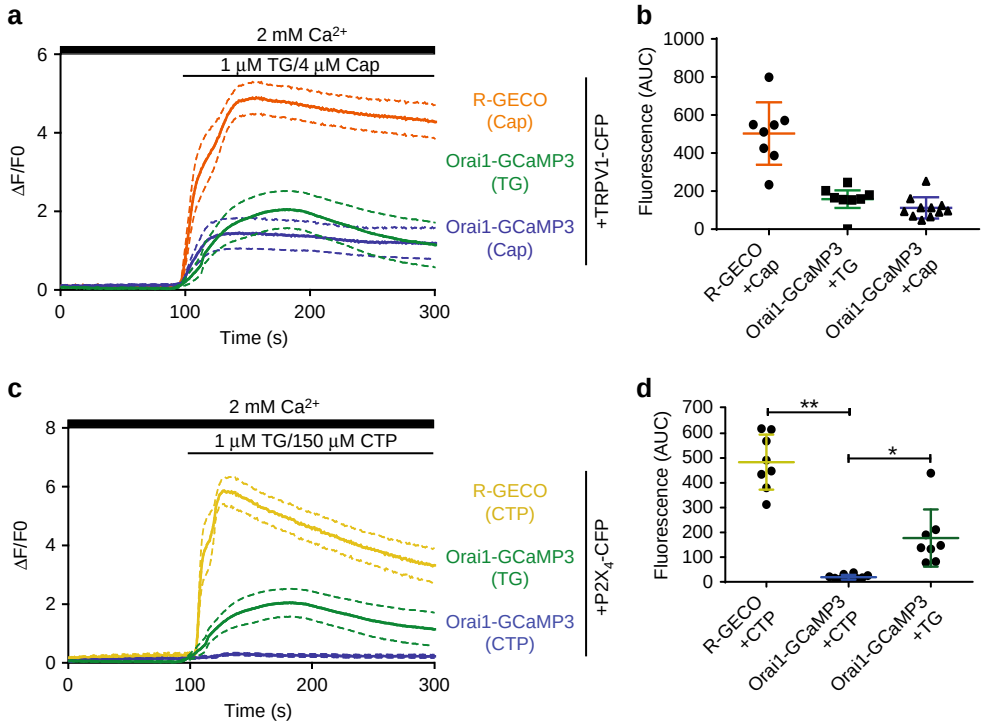
We decided to characterize in greater detail the interactions between Orai1-TRPV1 and Orai1-$P2X_4$ in an attempt to identify the molecular mechanism responsible for the differential sensing of calcium by Orai1-GCaMP3 when TRPV1 or $P2X_4$ are activated.

If Orai1-GCaMP3 is sensing increments in calcium upon activation of TRPV1 but not $P2X_4$, then the calcium accumulating in the proximity from Orai1 should have an effect on Orai1 CDI. To explore this hypothesis, we developed a sequential activation patch clamp protocol to induce channel activity first on TRPV1 or $P2X_4$ followed by the activation of Orai1 with TG and measure whole-cell currents in the perforated patch clamp mode. Control experiments consisting of perfusion with extracellular solution (Methods) provided a basal Orai1 activity and a control for CDI (Fig. 3a, b).

Activation of TRPV1 with capsaicin (Cap) followed by the activation of Orai1 with TG resulted in strong CDI (Fig. 3b, c).

This phenomenon was not observed when we activated $P2X_4$ with cytidine triphosphate (CTP) followed by the activation of Orai1 with TG (Fig. 3d, e). To further demonstrate that the rapid decay in Orai1 current was the result of CDI, we conducted experiments with the Orai1 mutant insensitive to CDI (Orai1-Y80W)[21]. Activation of TRPV1 followed by activation of Orai1-Y80W with TG did not induce significant CDI (Fig. 3f, g). Furthermore, using strong calcium buffering with BAPTA inside the cell (BAPTA-AM) further confirmed that the rapid reduction in Orai1 current was the result of CDI (Fig. 3b, d). The CDI observed in Orai1 after TRPV1 activation was evident at all voltages explored (Fig. 3h).

Fig. 1 Developing and testing the Orai1-GCaMP3 sensor. **a** Representative confocal images of the fluorescence obtained with Orai1-GCaMP3 (blue) and histone 2B fused to mCherry as nuclear marker (yellow) expressed in HEK293 cells obtained from at least 3 independent transfections. Left panels show the 3D (*x*, *y*, and *z* axes) confocal projections from Orai1-GCaMP3 to illustrate its plasma membrane localization. Scale bar 5 μM. **b** Western blot analysis from HEK293 cells expressing the Orai1-GCaMP3 sensor and Orai1-GFP (representative blot from 3 independent blots). Notice the 55 kDa band corresponding to endogenous Orai1 and the 79 kDa band from Orai1-GFP and the Orai1-GCaMP3 sensor. **c** Cell population calcium measurements using a spectrofluorometer with HEK293 cells expressing Orai1-GFP + STIM1-DsRed (yellow) or Orai1-GCaMP3 + STIM1-DsRed (green) or measuring the endogenous SOCE (black). Measurements obtained from at least 5 independent transfections. Calcium increments induced by the application of thapsigargin (TG) in free extracellular calcium and SOCE measured after re-addition of 2 mM calcium to the extracellular solution. **d** Area under the curve (AUC) for fluorescence obtained after re-addition of 2 mM calcium (calcium influx) with endogenous Orai1 (gray), Orai1-GFP (yellow), and Orai1-GCaMP3 (green). **e** Representative confocal images of the puncta formation after TG application in cells expressing Orai1-GCaMP3 (blue) and STIM1-DsRed (yellow). Images shown before the application of thapsigargin (pre-TG) and after (post-TG) for the equatorial plane (middle) of the cell (EP) and the cortical plane (CP, the plane closest to the Petri dish bottom). Scale bar 5 μM. **f** Co-localization index (PC, Pearson's correlation coefficient) for Orai1-GCaMP3 + STIM1-DsRed before and after TG. **g** Co-localization index (PCC) for Orai1-GFP + STIM1-DsRed before and after TG. In all cases, data shows the mean ± standard deviation from at least 6 independent transfections. Asterisks show *p* values of < 0.01. The statistical significance was $p < 0.05$. Statistics was performed by Student's *t*-test



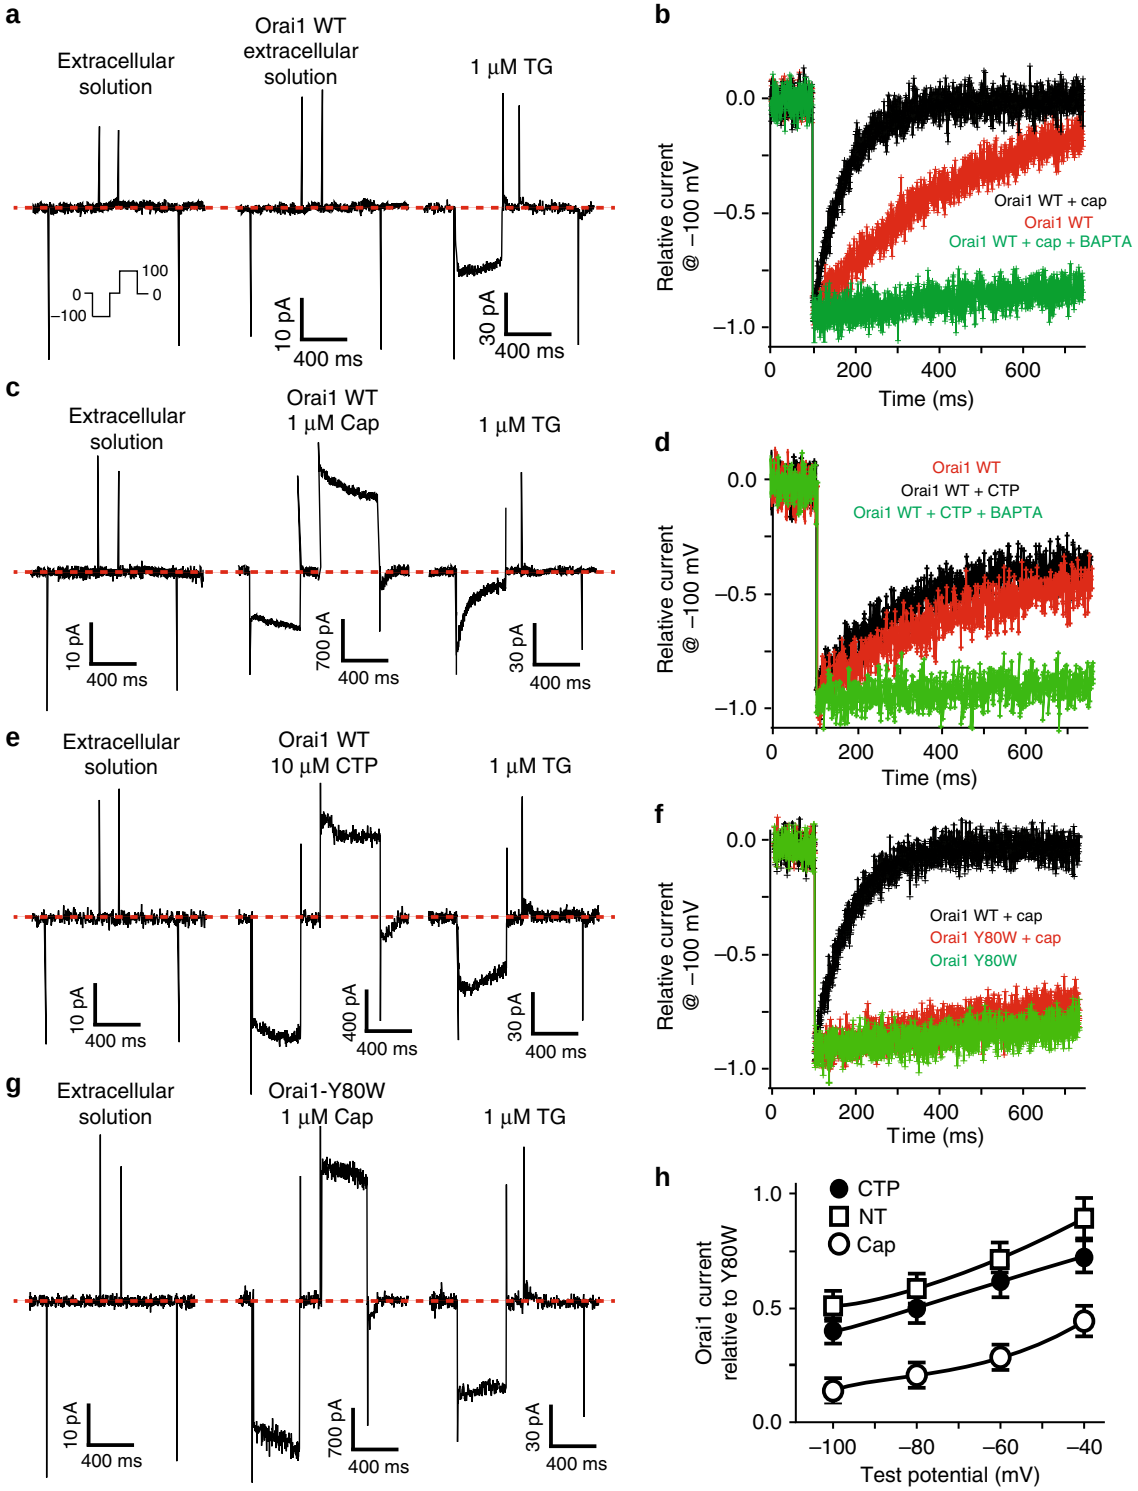


Fig. 2 Orai1-GCaMP3 senses local calcium increments through TRPV1 but not through $P2X_4$. **a** Calcium increments reported by R-GECO when the cells were exposed to capsaicin, Orai1-GCaMP3 with capsaicin and Orai1-GCaMP3 with thapsigargin (TG) from at least 12 independent transfections. **b** Area under the curve (AUC) for fluorescence of R-GECO with capsaicin (orange), Orai1-GCaMP3 with capsaicin (blue), and Orai1-GCaMP3 with TG (green). **c** Calcium increments reported by R-GECO when the cells were exposed to CTP, Orai1-GCaMP3 with CTP, and Orai1-GCaMP3 with thapsigargin (TG). **d** Area under the curve (AUC) for fluorescence of R-GECO with CTP (yellow, $n = 8$), Orai1-GCaMP3 with CTP (blue, $n = 10$), and Orai1-GCaMP3 with TG (green, $n = 8$). Notice that Orai1-GCaMP3 does not sense calcium increments with CTP while the R-GECO reports large calcium increments. In all cases, data shows the mean ± s.e.m. $^{**}p < 0.01$, $^{*}p < 0.05$. The statistical significance was $p < 0.05$. Statistics was performed by one-way ANOVA with Tukey's post hoc test

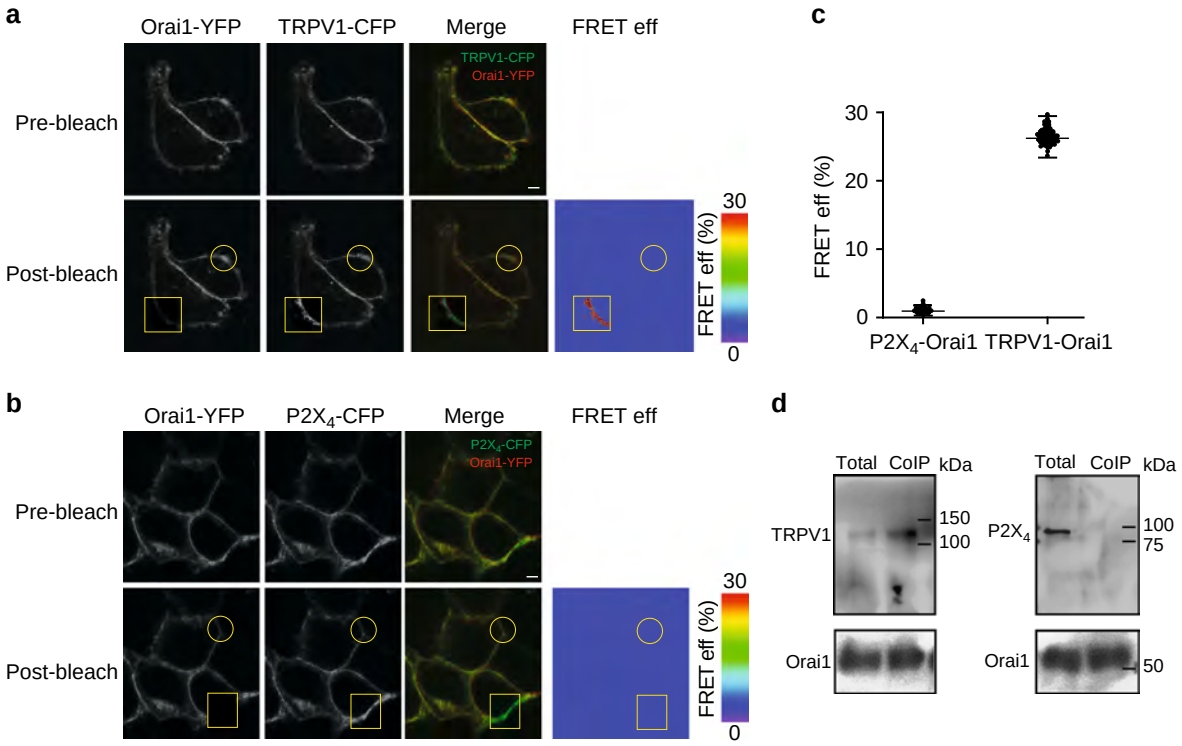
Orai1 is in close proximity to TRPV1 but not to $P2X_4$. If calcium entering TRPV1 is inducing strong CDI in Orai1 but not calcium entering through $P2X_4$, this result strongly suggests that TRPV1 and Orai1 must be in close proximity from each other. Indeed FRET analysis indicates that Orai1-YFP and TRPV1-CFP are within less than 10 nm from each other (Fig. 4a, c). FRET was not observed between Orai1-YFP and CFP-$P2X_4$ (Fig. 4b, c). These results were confirmed by CoIP studies with Orai1-TRPV1 and Orai1-$P2X_4$ (Fig. 4d, for full-length blots see Supplementary Fig. 3).

To explore at the single channel level how calcium entering TRPV1 is sensed by our Orai1-GCaMP3 fusion protein, we conducted super resolution studies. Super resolution imaging showed individual Orai1, TRPV1, and $P2X_4$ channels freely diffusing at the PM of living cells (Fig. 5a and Supplementary Movies 1 and 2). Measuring the distance between Orai1-TRPV1 and Orai1-$P2X_4$ confirmed the results obtained by FRET and CoIP. The distance between individual Orai1 and TRPV1 channels was significantly smaller than that between Orai1-$P2X_4$ (Fig. 5b). Average distances over time obtained from hundreds of single channels showed at least a 4-fold greater distance between Orai1 and $P2X_4$ compared to Orai1 and TRPV1 (Fig. 5c). Furthermore, super resolution imaging of fluorescence increments using Orai1-GCaMP3 single channels showed that

this fusion protein could sense calcium increments arising from TRPV1 but not $P2X_4$ channels (Fig. 5d, e and Supplementary Movies 1 and 2). These differences in sensing calcium from TRPV1 or $P2X_4$ were evident also when measuring the average change in fluorescence from hundreds of single Orai1-GCaMP3 channels (Fig. 5f, g).

ANK1 of TRPV1 is essential for the association to Orai1 C terminus. To identify the molecular structures responsible for the association between Orai1 and TRPV1 channels, we conducted a wide screening using peptide microarrays with a platform we have previously developed and tested[24] (data available here[25]). Previous studies have highlighted the role of the ankyrin domains from TRPV1 in the association to regulatory proteins and scaffolds[26]. To evaluate the role of each of the 6 ankyrin domains from TRPV1 we produced fusion proteins of each domain to the green fluorescent protein (GFP) and conducted CoIP studies using Orai1 as bait. CoIP analysis indicated that the first 3 ankyrin domains associate to Orai1, although the first ankyrin domain (ANK1) showed to strongest interaction (Fig. 6a, for full-length blots see Supplementary Fig. 4). To explore further to what sequence from Orai1 was the ANK1 associating, we produced

Fig. 3 Activation of TRPV1 induces strong CDI in Orai1. **a** Perforated patch measurements in HEK293 cells expressing Orai1-GFP and STIM-DsRed. The sequential protocol consisted in the application of extracellular solution followed by a second control application of extracellular solution (ES) and finally thapsigargin. The second ES application will be replaced by either capsaicin or cytidine triphosphate (CTP) in the following experiments. In all cases, capsaicin or CTP were incubated for 3 min and then the cells were washed with fresh ES for 1–2 min prior to TG stimulation (TG was present for the remaining duration of the experiment). **b** Relative current illustrating the activation by applying a voltage step from 0 to −100 mV for cells expressing Orai1 and TRPV1 pre-stimulated with capsaicin (cap, black), Orai1 only with thapsigargin (red), and Orai1 and TRPV1 pre-stimulated with capsaicin in cells incubated with BAPTA-AM (green). **c** Perforated patch measurements using the sequential protocol pre-simulating with capsaicin in cells expressing Orai1-GFP and TRPV1-CFP. The middle panel shows the currents elicited by capsaicin stimulation (TRPV1). Panel to the right shows the subsequent activation of Orai1 with TG. **d** Relative current illustrating the activation of current by applying a voltage step from 0 to −100 mV for cells expressing Orai1 and activated by TG (red), cells expressing Orai1 and $P2X_4$ and pre-stimulated with CTP (black) and cells expressing Orai1 and $P2X_4$ and pre-stimulated with CTP and previously incubated with BAPTA-AM (green). Lines show mean ± standard deviation from at least 31 cells. **e** Perforated patch measurements using the sequential protocol in a cell expressing Orai1 and $P2X_4$. **f** Relative current illustrating the activation for cells expressing Orai1 wild type (WT) with pre-stimulation with capsaicin (black) and cells expressing the CDI-resistant mutant Orai1 Y80W with (red) or without pre-stimulation (green). **g** Perforated patch measurements using the sequential protocol in cells expressing Orai1 Y80W and TRPV1. **h** Orai1 currents relative to mutant Orai1 Y80W at different voltages. Cells pre-stimulated with CTP (black circle), with capsaicin (open circle) or cells not exposed to capsaicin, only TG (NT). All experiments show the mean ± standard deviation from at least 20 cells



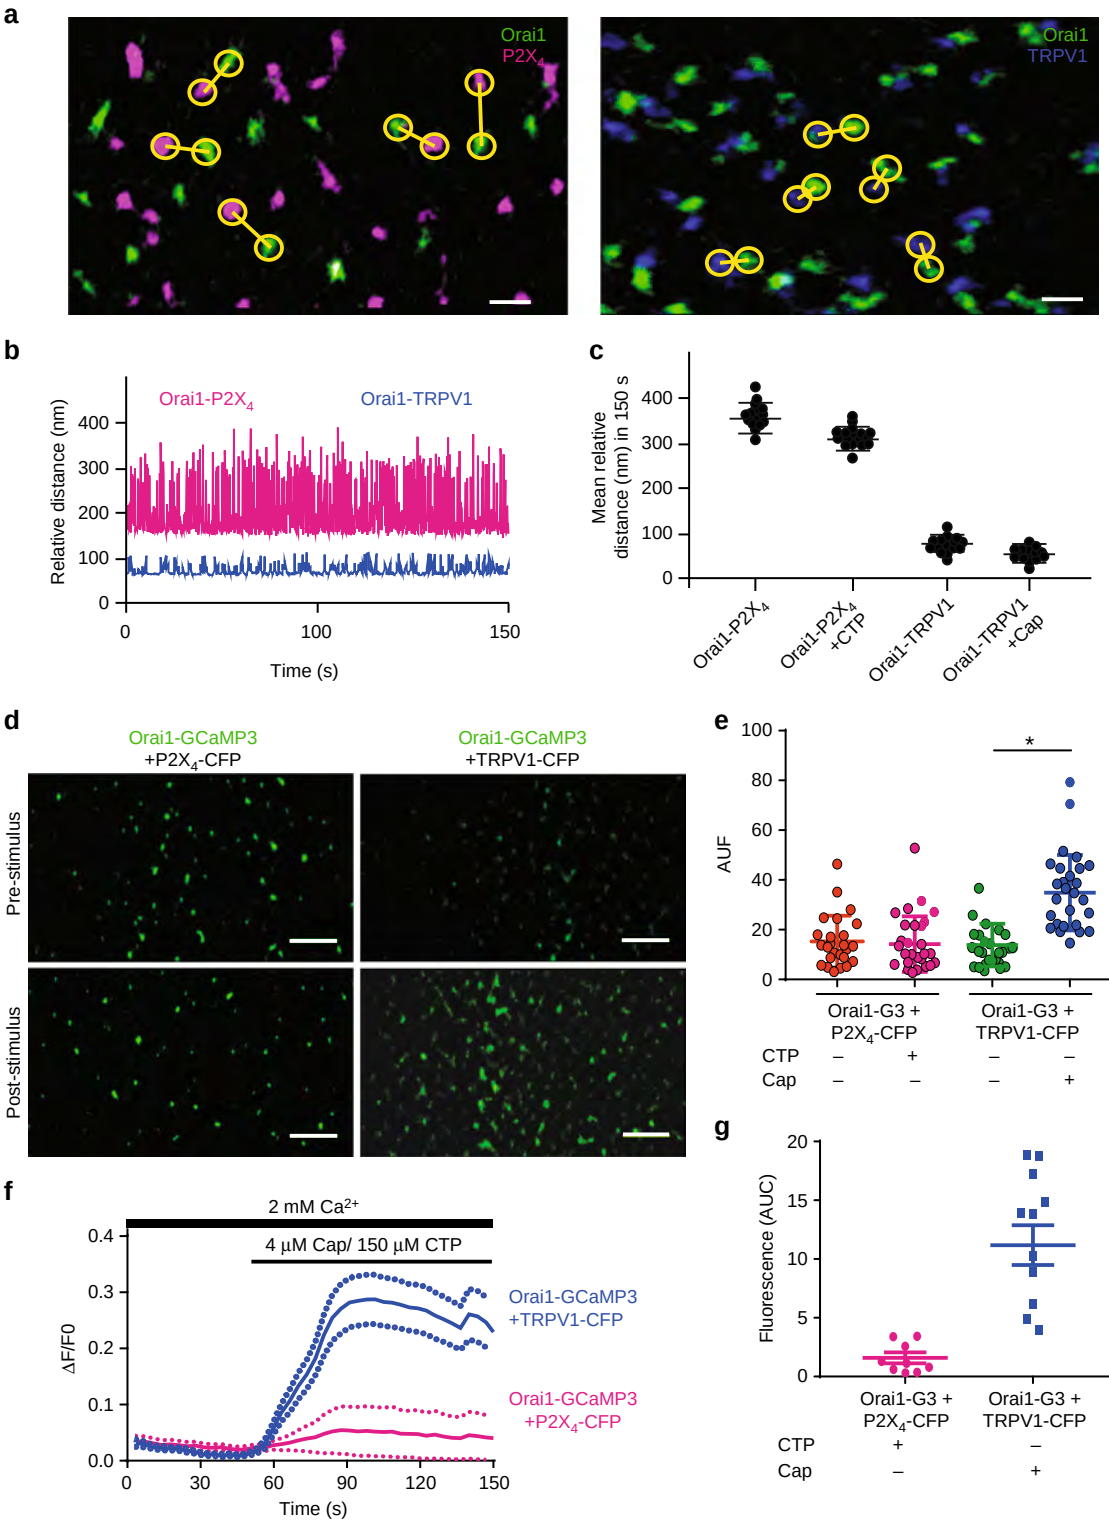


Fig. 4 TRPV1 is in close proximity to Orai1. **a** Representative confocal images illustrating the expression of Orai1-YFP and TRPV1-CFP before (pre-bleach) or after (post-bleach) photobleaching of the acceptor (YFP). The square shows the area photobleached and the circle a control area not exposed to the photobleach procedure. We used both areas to calculate the FRET efficiency as indicated in Methods. Right panel shows the FRET efficiency (FRET eff) in pseudo color calculated from the acceptor photobleaching protocol (Methods). Scale bar 1 μM. **b** Representative confocal images illustrating the expression of Orai1-YFP and $P2X_4$-CFP before (pre-bleach) or after (post-bleach) photobleaching of YFP. The square shows the area photobleached and the circle a control area not exposed to the photobleach procedure. FRET efficiency (FRET eff) in pseudo color calculated from the acceptor photobleaching protocol (Methods). Scale bar 1 μM. **c** FRET eff (%) obtained from at least 45 cells for $P2X_4$-Orai1 and TRPV1-Orai1. Data show the mean ± standard deviation. **d** Co-immunoprecipitation analysis of cells expressing c-Myc-Orai1 and TRPV1-YFP or $P2X_4$-CFP (for the entire blots check Supplementary Figures). Total indicates the protein that was not retained in the affinity column, thus reflects the protein that did not co-immunoprecipitate (Methods). Blots are representative examples from at least 3 independent blots

fusion proteins between the amino terminus from Orai1 and GFP (Orai1-NH2-GFP) and the carboxyl terminus from Orai1 (Orai1-COOH-GFP). Peptide microarray studies showed that the strongest interaction was between ANK1 and COOH-GFP (Fig. 6b). COOH-GFP interacts with the first 3 ankyrin domains from TRPV1, but the strongest interaction is with ANK1 (Fig. 6c). To ensure that the amount of Orai1-COOH deposited on each microarray spot was not affecting the binding of the different ankyrin domains, we produced a fusion protein of the carboxyl terminus from Orai1 fused to the red fluorescent protein (Orai1-COOH-DsRed). In this way, we can determine how much of the Orai1-COOH-DsRed was deposited on each microarray spot (using the red fluorescence channel) and the binding from the 6-ankyrin domains fused to GFP (using the green fluorescence channel), simultaneously (Methods). Below the strips of the microarray from the 6 ankyrin domains are illustrated examples

INFORME DE LABORES 2019

of the Orai1-COOH-DsRed deposited on the microarray coverslip for each condition (Fig. 6c, lower panels labeled Orai1-COOH-DsRed)[25].

To explore the role of the first 3 ankyrin domains in the entire TRPV1 protein, we produced individual deletions of these 3 ankyrin domains. Unfortunately, only the deletion of the first ankyrin domain produced channels that reached the PM, deleting beyond this first ankyrin domain resulted in channels that were retained in intracellular compartments. This finding was previously reported, showing that only the first amino acids from the amino terminus of TRPV1 can be deleted without affecting channel localization and function[26]. In particular, the ankyrin domain 3 plays a key role in channel tetramerization[27]. Nevertheless, we could explore the role of the first ankyrin domain on CDI using the deletion mutant TRPV1-ΔANK1, which is lacking the first ankyrin domain (Methods).

Fig. 5 Super resolution studies reveal that TRPV1 and Orai1 move in close proximity in the plasma membrane. **a** Super resolution single channel TIRFM images from cells expressing Orai1 (green) and $P2X_4$ (magenta) in the left panel or Orai1 (green) and TRPV1 (blue, right panel). Yellow circles show measurements between the nearest two channels for Orai1-$P2X_4$ (left panel) or Orai1-TRPV1 (right panel). Scale bar 60 nm. **b** Relative distance over time for a single pair of channels measured in cells expressing Orai1-$P2X_4$ (magenta) and Orai1-TRPV1 (blue). **c** Mean relative distance obtained from several hundred channels in cells expressing Orai1-$P2X_4$ (magenta) with or without CTP and Orai1-TRPV1 (blue) with or without capsaicin. Notice that agonist stimulation (CTP or capsaicin) did not alter mean distances. **d** Super resolution single channel TIRFM images from cells expressing Orai1-GCaMP3 (green) + $P2X_4$-CFP (left panels) or TRPV1-CFP (right panels) before and after stimulation with CTP or capsaicin. Notice the increment in the fluorescence of single Orai1-GCaMP3 channels after capsaicin stimulation but not with CTP. Scale bar 200 nm. **e** Fluorescence intensity in arbitrary units (AUF) reported by the Orai1-GCaMP3 sensor under the different stimulations. Notice that only cells expressing TRPV1 (T1-CFP) exposed to capsaicin produced an increment in fluorescence (blue bar). Capsaicin stimulation in cells without TRPV1 (orange and magenta bar) or cells expressing TRPV1-CFP but not exposed to capsaicin (green bar) did not result in changes in the fluorescence of Orai1-GCaMP3. **f** Fluorescence measurements of the entire field of view (containing dozens of individual channels) over time with cells expressing the Orai1-GCaMP3 sensor and TRPV1 with capsaicin (blue line) or cells expressing $P2X_4$ and stimulated with CTP (magenta line). Lines show the mean ± standard deviations (dotted lines). Fluorescence from Orai1-GCaMP3 sensor increases only after capsaicin stimulation in cells expressing TRPV1. **g** Area under the curve (AUC) for the different conditions shown in panel **f**. Notice that only the fluorescence is observed in cells expressing the Orai1-GCaMP3 sensor + the TRPV1 channel and stimulated with capsaicin (green bar). $^*p < 0.01$. The statistical significance was $p < 0.05$. Statistics was performed by Student's *t*-test

Super resolution imaging analysis showed that the relative distance between TRPV1-ΔANK1 and Orai1 was greater than that between TRPV1 wild type (TRPV1-WT) and Orai1 (Fig. 6d–f). Most interestingly, Orai1-GCaMP3 partially sense changes in calcium when TRPV1-ΔANK1 was activated with capsaicin compared to TRPV1-WT (Fig. 6g). Activation of TRPV1-WT and TRPV1-ΔANK1 with capsaicin results in robust increments in intracellular calcium reported by R-GECO produced as a soluble protein in the cytosol (Supplementary Fig. 5), discarding the possibility that the reduced sensing of calcium entering via TRPV1-ΔANK1 by Orai1-GCaMP3 may be the result of reduced calcium influx by the TRPV1-ΔANK1 deletion mutant. Furthermore, TRPV1-ΔANK1 does not co-immunoprecipitate with Orai1 (Supplementary Fig. 5).

Activation of TRPV1-ΔANK1 using our sequential activation patch clamp protocol showed only reduced CDI in Orai1 while TRPV1-WT produced strong CDI as previously shown (Fig. 3 and Supplementary Fig. 6). To discard any nonspecific effects of capsaicin on ionic currents, we conducted additional controls using the synthetic antagonist of capsaicin, capsazepine (Supplementary Fig. 5). Capsazepine stimulation had no effect on Orai1 CDI. Furthermore, the activation of TRPV1 with capsaicin in cells incubated with BAPTA-AM showed no effect on Orai1 CDI, strongly supporting the hypothesis that the CDI observed on Orai1 is the result of increments in intracellular calcium mediated by TRPV1 (Supplementary Fig. 5).

These results highlight the role of the first ankyrin domain in the association of TRPV1 to the carboxyl terminus from Orai1. This molecular interaction supports the formation of a complex between Orai1 and TRPV1, bringing the two channels in close proximity. This association between both channels favors the generation of a calcium microenvironment near the Orai1 channel pore when TRPV1 is activated, which modulates CDI on Orai1. The strong CDI observed in Orai1 channels induced by the activation of TRPV1 remains even after TRPV1 is not active anymore (Fig. 3c). These results suggest that calcium entering TRPV1 triggers the initial steps of CDI on Orai1 channels, but a sustained mechanism maintains CDI even when the influx of calcium through TRPV1 has been stopped (by washing out capsaicin). The sustain CDI can be explained by the fact that FCDI is modulated by Orai1-STIM1 interactions and not only high calcium near the Orai1 pore. Such Orai1-STIM1 interactions are mediated by the STIM1-Orai1 expression ratio[16] an amino acid region negatively charged in STIM1 (residues 475–483)[17–21] from Orai1[22].

CDI may prevent excessive calcium entry into the cell when both channels (TRPV1 and Orai1) are activated simultaneously or sequentially.

To facilitate the study of the interactions between TRPV1 and Orai1 and the identification of the amino acid domains involved in this association, we conducted all the experiments described to this point in HEK293 cells. However, in order to assess the effect of TRPV1-induced CDI on Orai1 channels in a physiological model, we implemented a scratch-wound assay (SWA) using primary cultures of cortical astrocytes. We have previously shown that the majority of thrombin-activated calcium influx in cortical astrocytes is carried by Orai1 channels[28]. Cortical astrocytes express TRPV1 channels[29]. Furthermore, thrombin plays a key role in astrocyte migration and wound healing[30–32].

First, we validated that our Orai1-GCaMP3 sensor behaved in astrocytes similarly to what we have observed in HEK293 cells. Indeed, primary cultures of cortical astrocytes expressing our Orai1-GCaMP3 calcium sensor responded to capsaicin stimulation but not to the activation of $P2X_4$ purinergic receptors with CTP (Fig. 7a). Nevertheless, astrocytes respond normally to CTP with a robust increment in intracellular calcium measured with the soluble calcium sensor R-GECO (Fig. 7a). Orai1-GCaMP3 senses also calcium increments induced with TG (Fig. 7a). All these results recapitulate what we observed with HEK293 cells expressing our Orai1-GCaMP3 construct (Fig. 2).

Capsaicin induces CDI on endogenous Orai1 currents from cortical astrocytes but not CTP stimulation (Fig. 7b). Furthermore, expression of the first ankyrin domain in astrocytes (ANK1-GFP) reduces the amount of CDI obtained with capsaicin pre-stimulation in our sequential perforated patch clamp protocol (Fig. 7c, d). Endogenous TRPV1 immunoprecipitate with endogenous Orai1 in cortical astrocytes (Supplementary Fig. 7), similarly to what we observed with the overexpression of these channels in HEK293 cells (Fig. 4d).

Using the SWA model, we have found that endogenous Orai1 participates in thrombin-induced cell migration and wound healing with cortical astrocytes, since transfection with a selective siRNA for Orai1[28] prevents the effects of thrombin on wound healing (Supplementary Fig. 7).

Capsaicin stimulation previous to activation of Orai1 with thrombin significantly reduces wound healing (Fig. 7e, f), this effect is not observed with the synthetic antagonist of capsaicin, capsazepine (Supplementary Fig. 7). Expressing the ANK1-GFP domain in cortical astrocytes prevents the effect of capsaicin on thrombin-induced wound healing (Fig. 7e, f).

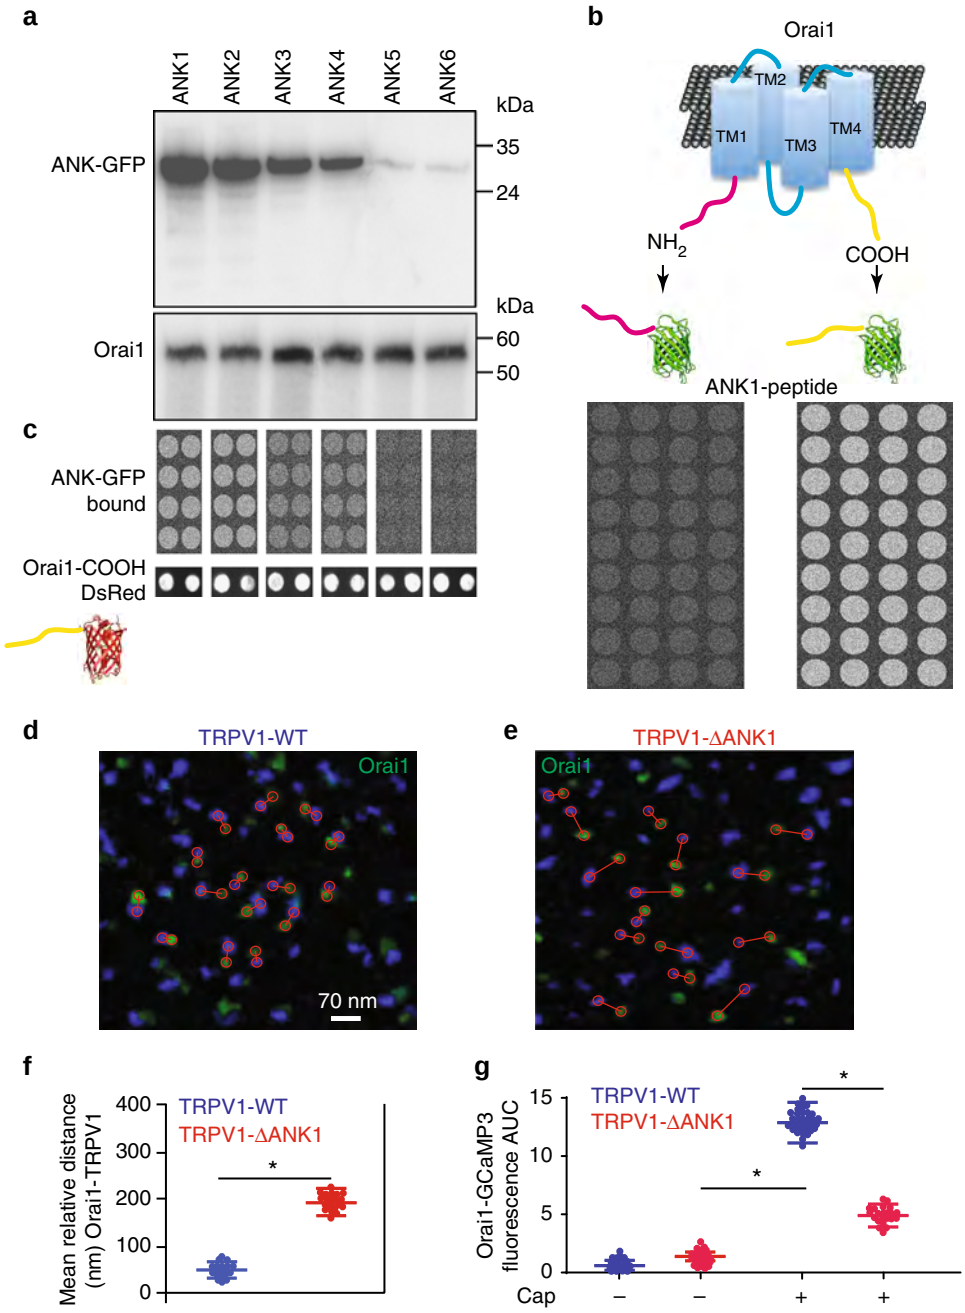

Fig. 6 The first ankyrin domain from TRPV1 associates to the carboxyl domain from Orai1 to favor TRPV1-Orai1 association. **a** Co-immunoprecipitation analysis of cells expressing c-Myc-Orai1 and the 6 ankyrin domains fused to GFP (ANK1-ANK6). **b** Cartoon showing the fusion of the amino or the carboxyl terminus from Orai1 to GFP. Lower panels show the results of the peptide microarrays using ANK1 as bait. Notice that only COOH-GFP is captured by ANK1 but not NH2-GFP. **c** Peptide microarrays using the 6 ankyrin domains individually fused to GFP. In this case Orai1-COOH is used as bait (printed on the glass coverslip). Notice that Orai1-COOH retained ANK1-GFP, ANK2-GFP and less efficiently ANK3 and ANK4 but not ANK5 and ANK6. **d** Super resolution TIRFM images of cells expressing TRPV1 wild type (TRPV1-WT, blue) and Orai1 (green) or cells expressing TRPV1-ΔANK1 (right panel, **e**). Red circles show the distance between the closest pair of channels and the lines connect the pair. **f** Mean relative distance obtained from hundreds of individual channels for Orai1 with TRPV1-WT (blue) or TRPV1-ΔANK1 (red). Data shows the mean ± standard deviation. **g** Fluorescence increments reported by the Orai1-GCaMP3 sensor with and without capsaicin stimulation. Notice that the Orai1-GCaMP3 increases about half the fluorescence after capsaicin in cells expressing TRPV1-ΔANK1 (red bar) compared to the cells stimulated with capsaicin and expressing TRPV1-WT (green). This indicates that deletion of the first ANK domain results in Orai1 moving apart from TRPV1 and the Orai1-GCaMP3 sensor reporting less of the calcium that enters through the TRPV1 channel. $^{*}p < 0.01$. The statistical significance was $p < 0.05$. Statistics was performed by one-way ANOVA with Tukey's post hoc test

All these results strongly suggest that the activation of endogenous TRPV1 channels in cortical astrocytes modulate the activity of endogenous Orai1 channels by inducing CDI and reducing calcium entry through Orai1 channels. Enhanced CDI reduces thrombin-induced cell migration and wound healing. The results presented here provide the first evidence, to our knowledge, of the role of Orai1 in thrombin-activated cell migration and wound healing, while highlighting the role of CDI on Orai1 activity during this physiological process.

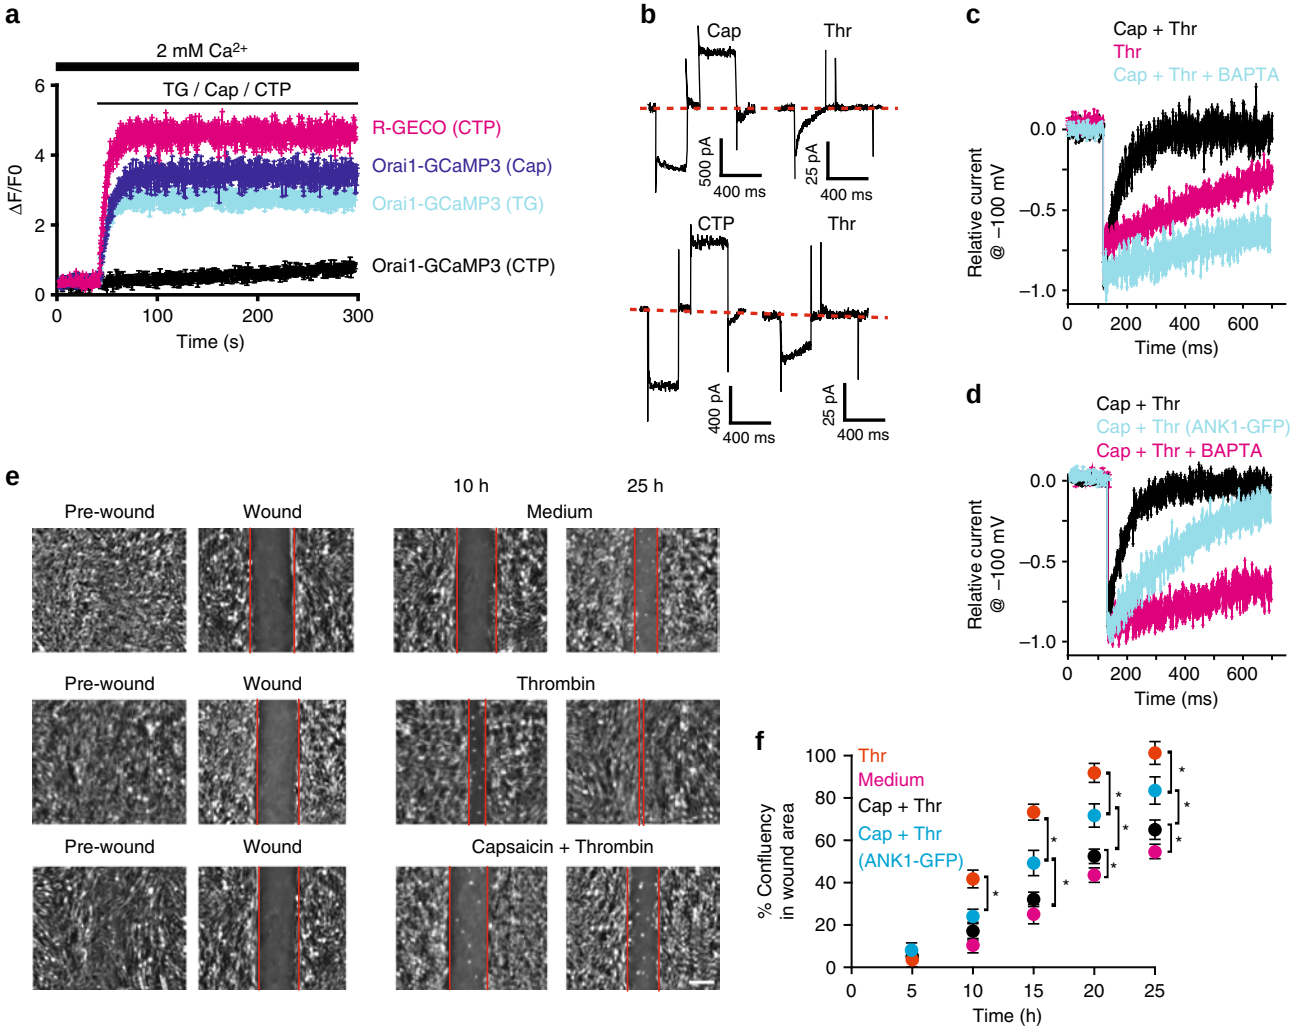

Fig. 7 TRPV1 induced CDI on Orai1 modulates wound healing. **a** Cell population calcium measurements obtained with cortical astrocytes primary cultures transfected with Orai1-GCaMP3. Endogenous TRPV1 and $P2X_4$ were used. Orai1-GCaMP3 senses calcium increments evoked with capsaicin (500 nM, blue) and TG (1 μM, cyan) but not with CTP (black). CTP induces robust calcium increments as reported by R-GECO (magenta). Data shows the mean ± standard deviation from at least 10 independent measurements obtained from 5 different cultures. **b** Stimulation with capsaicin (500 nM) prior to activation of Orai1 with thrombin induces strong CDI. CTP stimulation induces large $P2X_4$ currents, however not CDI in Orai1 (activated by thrombin). **c** Perforated patch measurements of currents evoked by a voltage step from 0 to −100 mV in response to capsaicin followed by thrombin (black lines), thrombin alone (magenta) and capsaicin + thrombin in cells incubated with BAPTA-AM (cyan). BAPTA incubation strongly reduces CDI in cells stimulated with capsaicin and thrombin. Capsaicin incubated for 3 min and then the cells were washed with fresh PBS for 3 min prior to thrombin stimulation. **d** Perforated patch measurements of currents evoked by a voltage step from 0 to −100 mV in response to capsaicin + thrombin in cells expressing TRPV1 (black) and cells expressing also the ANK1-GFP domain (cyan) and cells incubated with BAPTA-AM (magenta). **e** Scratch-wound assay in cortical astrocytes. Representative photographs of the cell culture around the wound area are shown for 10 and 25 h after wound. Medium shows the cells that were maintained in DMEM. Thrombin indicates cells treated with thrombin (5 U mL^{-1} thrombin) for 3 min[42]. Cell cultures were exposed to capsaicin (500 nM) for 3 min and then incubated with thrombin (5 U mL^{-1} thrombin) for 3 min. **f** Percentage of confluency in wound area under the different treatments shown in **e**. Cells were also transfected with a construct carrying ANK1-GFP (blue). Data points show the mean ± standard deviation from at least 5 cell culture dishes for each condition. *$p < 0.01$. The statistical significance was $p < 0.05$ according to ANOVA

Discussion

The present study identifies the molecular determinants of the association between TRPV1 and Orai1 channels, which favor heterologous CDI of Orai1 by calcium entering through single TRPV1 channels. Using super resolution studies on living cells, we observed that both channels move associated at the PM. This physical interaction results in relevant physiological modulation of channel activity (TRPV1 contributes to CDI on Orai1). This was not observed for another channel that does not associate to Orai1, the purinergic $P2X_4$ receptor, even though activation of this receptor/channel results in robust increments in cytosolic calcium as reported by our cytosolic soluble sensor, R-GECO.

CDI is a regulatory process that prevents excessive calcium influx via Orai channels, which may have deleterious or toxic effects in the cell. Up until now, this phenomenon has been studied using electrophysiological whole-cell current measurements evoked by Orai channels. To induce CDI under these conditions, the extracellular and/or intracellular calcium concentrations have been artificially controlled. To our knowledge, this is the first report showing that a physiological source of calcium (e.g., activation of TRPV1) can induce CDI on Orai1 both in an heterologous expression system (HEK293 cells) and in cell that naturally express both channels (cortical astrocytes). We have shown that the induction of CDI is the result of the close

proximity between Orai1 and TRPV1 at the PM, since the activation of a different channel ($P2X_4$) did not induce CDI on Orai1. Furthermore, super resolution studies show that both channels (TRPV1 and Orai1) move in close proximity to each other. This was not observed for $P2X_4$ and Orai1. The use of our local calcium reporter Orai1-GCaMP3 in super resolution studies shows that Orai1 single channels detect increments in calcium mediated by the activation of TRPV1 while freely diffusing at the PM. However, our Orai1-GCaMP3 sensor does not detect increments in calcium mediated after the activation of $P2X_4$. These results obtained with super resolution studies indicate that Orai1 and TRPV1 are moving in close proximity to each other, maintaining a microenvironment where calcium entering via TRPV1 accumulates and induces CDI in Orai1.

Super resolution analysis showed at least a 4-fold greater distance between $P2X_4$ and Orai1, when compared to the distance between TRPV1 and Orai1 (Fig. 5). The average distance between individual TRPV1 and Orai1 channels obtained from super resolution studies was around 50 nm. This distance contrasts to that observed with our FRET studies (less than 10 nm). The discrepancy can be explained by the resolution limits attained by both methods. While FRET detects distances between two proteins smaller than 10 nm (100 Å), the super resolution method (even though has gone beyond the light diffraction limit) it is still far away from the resolution of FRET. For example, STED (stimulated emission depletion) imaging has achieved a resolution of 20 nm when using organic dyes and 50–70 nm resolution when using fluorescent proteins[33]. The association of Orai1 and TRPV1 channels was evaluated also with CoIP studies. Even though all CoIP studies presented here are in agreement with the FRET and super resolution results, we would like to highlight the fact that the molecular weight obtained from Orai1 (≈55 kDa) differs from the predicted molecular weight for this protein (≈33 kDa). Thus, we would like to take the CoIP studies with caution, even though other reports have found similar discrepancies in the molecular weight for Orai1[34,35]. Feasible explanations for the higher molecular weight observed may involve glycosylation, phosphorylation, and other post-translational modifications of Orai1[36–38].

We have identified the first ankyrin domain (ANK1) as a structure responsible for the association of TRPV1 to the carboxyl terminus from Orai1. Deletion of this ANK1 domain (TRPV1-ΔANK1) prevents TRPV1-mediated CDI on Orai1. Single Orai1-GCaMP3 channels do not longer sense calcium entering through TRPV1-ΔANK1.

A previous study shows that capsaicin inhibits Jurkat T-cell activation by blocking I_{CRAC}[39]. Other studies have also shown that capsaicin or TRPV1 activation inhibits SOCE[40–43]. However, the molecular mechanism for these observations remained unknown until now.

CDI is a complex process, which involves the participation of several proteins such as SARAF[11], caveolin, E-syt1, septin4, and $PI(4,5)P_2$[13]. Furthermore, several amino acid regions have been identified in Orai1 and STIM1 to play a role in CDI[17–21]. This may be one of the reasons why CDI remained for several minutes after TRPV1 was not active anymore. Calcium entering through TRPV1 channel was the triggering event that initiated CDI in neighboring Orai1 channels, but other factors were involved in the sustained CDI even after the calcium source (TRPV1) was not active anymore (after washing out capsaicin).

In the present study, we focused our attention on the role of a different channel (TRPV1) in the induction of CDI on Orai1, to induced what we have named here heterologous CDI (as opposed to homologous CDI, which is induced by calcium entering via the Orai1 channel pore). We identified the ankyrin 1 domain from TRPV1 and the carboxyl terminus from Orai1 as sequences required for the association of these two channels. We cannot discard the participation of other proteins (as those mentioned above) or other amino acid regions in CDI. Further studies are required to evaluate the participation of other proteins and/or amino acid regions in Orai1 and TRPV1 in CDI.

Many cells and tissues express both TRPV1 and Orai1 channels, in particular cortical astrocytes. In these cells, activation of TRPV1 may modulate the subsequent (or concomitant) activation of Orai1 channels[44]. The role of astrocytes in chronic pain is well established[44]. We have previously shown that Orai1 mediates the thrombin response in cortical astrocytes[28]. Furthermore, thrombin induces cell migration and proliferation in astrocytes[30–32].

In the present study, we have shown that the activation of endogenous TRPV1 channels with capsaicin induces CDI on endogenous Orai1 channels from cortical astrocytes. In this study, we showed that the heterologous modulation of Orai1 by TRPV1 via CDI plays a role in controlling injury-promoted astrocyte migration (Fig. 7). All these results provide the first evidence highlighting the role of heterologous CDI in controlling calcium entry via Orai1 and how this modulates migration in astrocytes primary cultures.

Methods

Plasmids and reagents. Capsaicin and the synthetic antagonist of capsaicin, capsazepine and cytidine triphosphate (CTP) were purchased from Sigma (St. Louis, MO). TG was purchased from Calbiochem (La Jolla, CA).

Plasmids Orai1-GFP, GCaMP3, STIM1-DsRed, H2B-mCherry, and Lck-GCaMP5 were purchased from Addgene (Cambridge, MA), R-GECO was a generous gift from Dr. Takeharu Nagai (Osaka University, Japan), TRPV1-CFP and TRPV1-YFP were kindly donated by Dr. Leon Islas-Suárez (Facultad de Medicina, UNAM), CFP-$P2X_4$ was a generous gift of Dr. Jorge Arreola (Instituto de Fisica, UASLP). Full length complementary DNA of human-Orai1 was inserted into GCaMP3 between BamHI and EcoRI to generate Orai1-GCaMP3. All constructs were fully sequenced before using them.

Ankyrin domains fused to GFP. Oligonucleotides were synthesized (Integrated DNA Technologies, Skokie, IL) to generate peptides corresponding to the amino acid sequences for the 6 ankyrin (ANK) domains from rat TRPV1 (Genbank NM_031982). Ankyrin domains were obtained from ref. [45].

Oligonucleotides were cloned in the pDrive plasmid after PCR amplification and cloned in frame at the 5′ of GFP. The resulting peptides were:

ANK1 110.152 (42 aa) RLYDRRSIFDAVAQSNCQELESLLPFLQRSKKRLTDSEFKDPE

ANK2 153.199 (46 aa) TGKTCLLKAMLNLHNGQNDTIALLLDVARKTDSLKQFVNASYTDSYY

ANK3 200.246 (46 aa) KGQTALHIAIERRNMTLVTLLVENGADVQAAANGDFFKKTKGRPGFY

ANK4 247.282 (35 aa) FGELPLSLAACTNQLAIVKFLLQNSWQPADISARDS

ANK5 283.331 (48 aa) VGNTVLHALVEVADNTVDNTKFVTSMYNEILILGAKLHPTLKLEEITNR

ANK6 332.358 (26 aa) KGLTPLALAASSGKIGVLAYILQREIH

Followed by the enhanced GFP sequence. All fusion genes were fully sequenced prior to use. For CoIP studies, the pcDNA 3.1 plasmid containing the nucleotide sequences for the 6 ankyrin domains individually fused to the GFP sequence (above) were transfected in HEK293 cells combined with the plasmid containing Orai1. For peptide microarray studies, the plasmids mentioned above were transfected in HEK293 cells maintained in suspension in 500 mL flasks to produce fusion proteins. Cells were harvested and sonicated to disrupt the cell membrane. Supernatants were immunoprecipitated using the commercial anti-GFP antibody (632376, Clontech, Mountain View, CA). Aliquots of the 6 ankyrin domains fused to GFP were utilized for TIRFM peptide microarray studies as previously described[46]. Briefly, silica glass was coated with a 0.01 mg mL^{-1} poly-D-lysine (Sigma, St. Louis, MO). Orai1-dsRED-COOH peptide was spotted on the microarray slide using a peptide solution of 500 ng in 50 µL. Approximately 2 µL were manually deposited on each spot using a pipette. Spots were allowed to dry for 20 min at room temperature prior to starting the TIRFM microarray experiment. Microarray slides were mounted on the lg-TIRFM closed chamber (TIRF Labs, Cary, NC).

A similar PCR strategy was conducted to produce the fusion proteins between the amino terminus from Orai1 and GFP (NH_2-GFP), the carboxyl terminus from Orai1 (COOH-GFP), and the carboxyl terminus from Orai1 fused to the red fluorescent protein (DsRed, Takara Bio, USA). Production and purification of recombinant fused proteins followed the procedure described above. The Orai1-COOH domain contained the last 38 amino acids (amino acid 200–238) with the sequence: HKTDRQFQELNELAEFARLQDQLDHRGDHPLTPGSHYA (Genbank:

AAH13386.1). Followed by the GFP or dsRED protein (Takara Bio, USA). The amino terminus of Orai1 contained the first 54 amino acids (1–54, Genbank: AAH13386.1): MSLNEHSMQALSWRKLYLSRAKLKASSRTSALLSGFAMVAMV EVQLDADHDYPP. Followed by the GFP protein. The deletion mutant TRPV1-RPV1-was produced by PCR amplification of TRPV1 cDNA using a forward oligonucleotide that started after nucleotide 536 (amino acid 153).

Cell culture and transfection. Human embryonic kidney 293 cells (HEK293; ATCC) were cultured using Dulbecco's modified Eagle's medium (DMEM) (GIBCO) supplemented with 10% (V/V) fetal bovine serum, 50 μg mL^{-1} penicillin–streptomycin and maintained at 37 °C in a humidified atmosphere with 5% CO_2.

Transient transfection was performed using Lipofectamine 2000 (Invitrogen) according to manufacturer instruction using cells seeded to 80% confluence in Optimem medium (GIBCO). Before imaging, culture medium was changed in Krebs solution (119 mM NaCl, 2.5 mM KCl, 1 mM NaH_2PO_4, 1.3 mM $MgCl_2$, 20 mM HEPES, 11 mM glucose, 1.8 mM $CaCl_2$, 500 μM EGTA and adjusted to 7.4 pH).

Western blot. Proteins of cells transfected with Orai1-GCaMP3 or Orai1-GFP were separated using SDS-Page with 10% acrylamide and transferred to the membrane using 110 V for 60 min in a wet chamber. A specific antibody was used to identify Orai1 (ab59330, Abcam) and for TRPV1 the antibody used was VR1 (sc-398417) from Santa Cruz Biotechnology. Primary antibody was incubated with agitation at 4 C° for 1 h. The secondary antibody was incubated for 2 h with agitation at room temperature. Signal was acquired using X-ray films and then the image was digitalized and analyzed using ImageJ software. Full-length blots are included in Supplementary Figures.

Confocal microscopy. HEK293 cells transfected with the different constructs and channels were plated on 25 mm coverslips. Cells were imaged in Krebs–Ringer's solution. TG (1 μM; Calbiochem) was used for store depletion. Image acquisition for co-localization experiments was conducted 12 min after store depletion. Enhanced GFP (EGFP), GCaMP3, DsRed, and R-GECO were excited at 488, 488, 494, and 594 nm, respectively. Fluorescence emission was collected at 500–540 nm for EGFP and GCaMP3 and 605–650 nm for DsRed and R-GECO. All images were captured at room temperature with a ×60, 1.40 numerical aperture oil-immersion objective lens controlled by Fluoview Olympus software on a FV10i confocal microscope (Olympus imaging). Pearson's correlation coefficient was calculated with Fluoview Olympus software.

Ca^{2+} measurements. Calcium imaging was performed in 25 mm coverslip with cells transfected with the plasmid of choice indicated in the figures. Cells expressing Orai1-GCaMP3 in Krebs–Ringer solution with Ca^{2+} were exposed to TG (1 μM) to induce store depletion. Capsaicin (4 μM) was utilized to activate TRPV1 channels and 150 μM cytidine triphosphate (CTP) to open $P2X_4$ channels. Calcium dynamics were measured in individual cells (at least 20 per coverslip per condition) using a wide-field inverted IX81 Olympus® microscope with a ×60 1.42 NA oil immersion objective, MT-20 illumination system, 420/10, 484/25 excitation filter, and 450, 550/25, 520 nm/40 bandpass and 605/40 bandpass emission filter with an EMCCD camera iXon-897 (Andor Technology, South Windsor, CT, USA). Sampling was acquired each second during 300 s. The acquired images were analyzed using Olympus Cell-R software. To measure calcium increments in cell populations, we loaded HEK293 cells with FURA-2 AM (Molecular Probes) at 2 μM final concentration. FURA-2 AM was incubated for 30 min at 25 °C. Calcium-free Krebs solution contained (119 mM NaCl, 2.5 mM KCl, 1 mM NaH_2PO_4, 1.3 mM $MgCl_2$, 20 mM HEPES, 11 mM glucose, 1 mM EGTA and adjusted to 7.4 pH). Then cells were rinsed with the same solution and were exposed to 1 μM TG to induce store depletion and Orai1 activation. Ca^{2+} entry was measured through an Aminco-Bowman luminescence spectrometer (Thermo Electron, Madison, WI). Dual excitation wavelength was selected at 340 and 380 nm and emission was collected at 510 nm. Fluorescence sampling was acquired each 10 s during 1000 s.

FRET measurements. The cells were seeded on 25 mm coverslips and co-transfected with TRPV1-CFP and Orai1-YFP. We performed FRET measurements using the acceptor photobleaching protocol with TRPV1-CFP as donor and Orai1-YFP as acceptor, as previously described[4].

For acceptor photobleaching, the images were acquired with an inverted Olympus FV1000 confocal microscope. The photobleaching of the acceptor was performed exposing the selected ROI to the laser at 50% of its maximum intensity (ROI indicated by a yellow square in Fig. 4), at a wavelength of 492 nm. This wavelength does not affect the donor as the excitation of GFP beyond 480 nm is negligible. The photobleaching protocol consisted of continuous excitation at 492 nm for 4 min, during this time, the fluorescence emission of CFP and YFP were monitored using the confocal microscope. Photobleaching excitation was alternated with image acquisition of CFP (460 nm) and YFP (520 nm). We used a 1.45 NA ×100 objective (Olympus, Japan) for image acquisition.

FRET efficiency, which indicates the percentage of excitation photons that contribute to FRET, was calculated measuring the fluorescence intensity in a ROI, before and after photobleaching the acceptor (Orai1-YFP), we also measured the fluorescence of acceptor and donor in a different ROI (without the photobleaching protocol applied, indicated by a yellow circle in Fig. 4) to correct for photobleaching that might occur during acquisition unrelated to the photobleaching protocol. FRET efficiency was calculated with the formula $E_{FRET} = (D_{post} - D_{pre})/D_{post}$, where D_{pre} and D_{post} are YFP fluorescence before and after the photobleaching protocol, respectively. The E_{FRET} calculated from the area not subjected to photobleaching (indicated by a yellow circle in Fig. 4) was considered the baseline. This baseline value was indistinguishable from the E_{FRET} obtained between Orai1-YFP and CFP-$P2X_4$ (Fig. 4). For a detailed description of the protocol, please refer to ref. [47].

Electrophysiology. HEK293 cells expressing the different constructs described in Fig. 3 were placed on coverslips coated with poly-lysine (Sigma). Cells were studied between 24 and 48 h post-transfection. Coverslips were mounted on an open perfusion chamber (TIRF Labs, Cary, NC). The patch clamp amplifier used for whole-cell recordings was the EPC-10 (Heka Electroniks, Germany). The patch clamp pipettes were prepared from Corning 7052 glass and had a resistance of 1–5 MΩ when filled with the pipette solution (see below). An Ag/AgCl electrode was utilized to attain electrical continuity and was connected to the bath solution via a KCl-agar bridge. TG was applied using a multibarrel perfusion system driven by gravity (TIRF Labs, Cary, NC).

Whole-cell currents were studied in the perforated patch mode. Amphotericin B was dissolved in 50 μL DMSO to give a 60 mg mL^{-1} stock solution and stored at −20 °C until use. The amphotericin B stock solution was dissolved to a final concentration of 0.24 mg mL^{-1} in a syringe containing the pipette solution: cesium aspartate 120 mM, EGTA 5 mM, HEPES 10 mM, $MgCl_2$ 2 mM, and NaCl 8 mM; pH to 7.2 adjusted with CsOH. The bath solution contained NaCl 120 mM, tetraethylammonium chloride (TEA-Cl) 10 mM, $CaCl_2$ 10 mM, $MgCl_2$ 2 mM, glucose 30 mM, and HEPES 10 mM; pH to 7.2 adjusted with NaOH. Osmolarity of both solutions was adjusted to 310 mOsm with mannitol (Sigma).

To determine Orai1 current inactivation, the cell was first stimulated with either 1 μM capsaicin (Cap) or 10 μM cytidine triphosphate (CTP) for approximately 1 min. The solution was removed and washout for 1–2 min with bathing solution before stimulation with 1 μM TG. Relative inactivation was obtained after obtaining the current density relative to the non-inactivating Orai1 Y80W mutant.

Current density was obtained after dividing the current from each cell by the cell capacitance (measured directly from the amplifier readout). The amplifier provided current density in real time calculated via the Patchmaster software and EPC10 electronics (Heka Electroniks, Germany). For time courses studying Orai1 whole-cell current activation, TG was applied while the cell membrane potential was held at −100 mV. All whole-cell current illustrated in Fig. 3 represents the mean ± standard deviation (SD) from at least 30 independent cells obtained from 4 different days and transfections.

Orai1 whole-cell currents were imported into Igor pro v. 7 (Wavemetrics, Oregon) for further analysis and plotting. Final figures were created with Adobe Illustrator (Adobe Systems).

Super-resolution microscopy. The total internal reflection fluorescence (TIRF) excitation (cellTIRF Illuminator; Olympus) system was mounted on an Olympus IX81 inverted microscope for all super resolution experiments reported here. The excitation angle was set up to attain the critical angle for total internal reflection, which provided a penetration of less than 100 nm. Cells were continuously illuminated using excitation sources depending on the fluorophore studied. Blue (CFP-$P2X_4$) and green (Orai1-YFP) were excited with either a 405 and 491-nm diode-pumped solid-state laser, respectively. Cells were continuously illuminated using the following excitation sources: blue (CFP-$P2X_4$) and green (Orai1-YFP) were excited with either a 405 and 491-nm diode-pumped solid-state laser, respectively. The maximum laser power, measured at the back of the focal plane of the objective lens, ranged between 20 and 25 mW, depending on the laser line used. Excitation wavelength and intensity were modulated using the Xcellence software v.1.2. A multiband laser cube set was used to discriminate the selected light sources (LF 405/488/561/635 A-OMF, Bright Line; Semrock). The microscope was equipped with an Olympus UApo N ×100/1.49-numerical-aperture oil-immersion objective lens with an extra ×1.6 intermediate magnification lens. All movies were recorded on a crop chip mode (512 × 32 pixels) of an EMCCD camera (Andox, Ixon 888) at 100 nm per pixel.

For each independent experiment, sub-diffraction images were derived from the Super Resolution Radial Fluctuation (SRRF) analysis[48]. Reconstructions contained thousands of TIRF images acquired within the evanescent field. All images were collected using stroboscopic illumination, alternating between laser lines in a per-frame basis, each with an exposure time of 1–5 ms.

Each serial stack (300 images block) was analyzed using the NanoJ-core and NanoJ-SRRF plugins of Image J[48,49]. For the analysis the following parameters were utilized: ring radius 0.5, radiality magnification 5, axes in ring 10; all other parameters were set up as the default options in NanoJ-core and NanoJ-SRRF plugins. The radiality maps were drift corrected using pre-calculated drift tables obtained with the Estimate Drift tool of NanoJ-SRRF, considering an average of 300 images. These drift-corrected radiality maps were then finally integrated on a super-resolution image by calculating the Temporal Radiality Pairwise Product Mean.

To obtain distances between Orai1 and TRPV1 or Orai1 and $P2X_4$ overtime, we used the tracking image correlation method[50]. For this purpose, HEK293 cells were transfected with a combination of Orai1-YFP and TRPV1-CFP or Orai1-YFP and CFP-$P2X_4$, respectively. The signal of individual fluorophores was tracked overtime by alternating the excitation wavelengths, as described above. Temporal blocks of 300 images were analyzed. Tracking image correlation (TrIC) computes a colocalization analysis on single particles along their trajectory based on local image cross-correlation. The accuracy of the correlation is limited to the SRRF, which in our case is between 40 and 60 nm. All of the analysis was programmed with MATLAB (The MathWorks, Natick, MA) using the original algorithms described by Dupont and collaborators[50]. Unlike the original study, which tracked particles in the 3D space, we conducted only 2D tracking within the depth of the evanescent wave (less than 100 nm). The depth resolution of TIRFM (less than 100 nm) provided high accuracy when determining the 2D spatial localization of the particles when compared to confocal microscopy, which in the best case scenario has a depth resolution of around 600 nm[51].

TIRFM microarrays. For peptide microarrays studies using ankyrin domains fused to GFP, we utilized a novel system specifically developed for this purpose based on total internal reflection microscopy (TIRFM)[46]. We have documented extensively this method elsewhere[46]. Briefly, purified peptides (either the ANK1 domain (see above) or the Orai1-COOH-DsRed terminal domain) were printed using a micropipette on conventional glass microarray slides previously coated with a film of 0.01 mg mL^{-1} poly-D-lysine (Sigma, St. Louis, MO). The microarray-closed chamber was bathed with a solution containing the ANK domains fused to GFP (see above) at a final concentration of 1 µM. After 3 min incubation, the chamber was bathed with saline solution and fluorescence signal was collected for 1 min. Excitation was in TIRFM mode using the LG-TIRFM system (TIRF Labs, Cary, NC). Excitation was alternated between 405 nm (GFP excitation) and 594 nm (DsRed excitation). DsRed emission was used to evaluate the amount of Orai1-COOH-dsRED deposited on each microarray spot. Microarray spots containing less than 80% of the average DsRed fluorescence were discarded because insufficient Orai1-COOH-dsRED was deposited in those spots. Emission of GFP (D505/40 m) and DsRed (ET620/60 m) were collected using high-quality single band emission filter from Chroma (Chroma Technology Corporation, Bellows Falls, VT, USA). For details on our TIRFM microarray system and protocols for microperfusion and fluorescence detection, please refer to ref. [24].

Co-immunoprecipitation. Plasmids c-Myc-Orai1 and TRPV1-YFP or CFP-$P2X_4$ were overexpressed in HEK293 cells. Cells were washed twice with PBS, then the cells were lysed with TNI lysis buffer[52] (0.5% Igepal CA-630, 50 mM Tris pH 7.5, 250 mM NaCl, 1 mM EDTA, 1× Complete ULTRA-EDTA-free protease Inhibitor cocktail) during 30 min at 4 °C with agitation and sonicated using a bath sonicator (55 kHz, 5 min). The samples were centrifuged 40 min (4 °C, 18,000×*g*) and the supernatant was incubated overnight with sepharose resin beads coupled to anti-c-myc antibody. Proteins were recovered by centrifuging the beads (4 °C, 500×*g*). Bound proteins were eluted with elution buffer[52] (0.2 M glycine pH 2.3 and 0.5% Igepal CA-630) during 30 min at 37 °C. The proteins were analyzed by western blot using specific antibodies c-myc (Invitrogen, MA1-21316) for c-Myc-Orai1 (50 kDa), VR1 (Santa Cruz, 398417) for TRPV1-YFP (125 kDa) and $P2X_4$ (Abcam, 134559) for CFP-$P2X_4$ (71 kDa), all the antibodies were used according to the manufacturer's recommendations. For endogenous Orai1 and TRPV1 from astrocytes we use the following protocol. Cells from 5 to 7 100 mm Petri dishes with confluent monolayers of primary culture astrocytes were rinsed and cells were detached mechanically. All cells from the Petri dishes were concentrated and lysed using TNI lysis buffer during 30 min with agitation at 4 °C and sonicated using a bath sonicator (55 kHz, 5 min). The samples were centrifuged 40 min (4 °C, 18,000×*g*) and the supernatant was incubated overnight with sepharose resin beads coupled to anti-Orai1 antibody. Proteins were recovered by centrifuging the beads (4 °C, 500×*g*). Bound proteins were eluted with elution buffer during 30 min at 37 °C. The proteins were analyzed by western blot using the specific antibodies described above.

Scratch-wound assay. Primary cortical astrocytes were isolated from rat brains[28]. All procedures for maintaining the rats and for isolation of astrocytes were approved by the Animal Care Committee of the Instituto de Fisiología Celular, Universidad Nacional Autónoma de México. Animal care was performed according to the International Guiding Principles for Biomedical Research Involving Animals (Council for International Organizations of Medical Sciences, 2010). Cortical astrocytes cultures were obtained from 1-day-old Wistar rat pups provided by our animal facility center. The astrocytes were isolated from the brain cortex of 6–8 pups. Brains were placed in Krebs solution and cut in small slices. The tissue was dissociated with a solution containing trypsin (4800 U mL^{-1}, Sigma, St. Louis, MO) for 10 min. Cells were mechanically dispersed by passage through 80 µm nylon mesh and resuspended in Eagle's medium (Gibco, Grand Island, NY) supplemented with 10% heat-inactivated fetal bovine serum (Gibco), 2 mM glutamine (Sigma), 50 U mL^{-1} penicillin (Gibco), and 50 µg mL^{-1} streptomycin (Gibco). The dissociated astrocytes were plated on 35 mm plastic Petri dishes and incubated at 37 °C in humidified 5% CO_2, 95% air atmosphere for 2 weeks.

When indicated astrocytes were transfected with the constructs described in the figure legends[28]. For RNA interference experiments, astrocytes cultures of 80% confluence in 35 mm plates were transfected with a set of three oligonucleotides of Stealth siRNAs for Orai1 (RSS357633, RSS357634, RSS357635) purchased from Invitrogen. A Stealth RNAi scramble negative control (Invitrogen) was used in parallel experiments. siRNAs transfection was carried out on primary astrocytes using Lipofectamine 2000 and Opti-MEM reduced serum medium according to the manufacturer's instructions (Invitrogen).

For the SWA, we followed the next protocol. Cover glass chambers (ThermoScientific, Rochester, NY) were coated with 0.01 mg mL^{-1} poly-D-lysine (Sigma, St. Louis, MO). Confluent primary cortical astrocytes were seeded onto chambers[28]. Once confluent, astrocytes were serum-deprived overnight. A single scratch with a 1 mL pipet tip was made through the astrocyte monolayer, cells were rinsed three times with serum-free media. The scratch area was marked with a sharpie for later identification and positioning in the microscope. Images of cells were obtained with a low magnification ×10 objective attached to an inverted IX81 microscope (Olympus). A low-resolution 5 MP USB c-mount microscope camera (Zowaysoon) attached to the microscope c-port was used to acquire individual images of the scratch wound area at 0 time (pre-wound), immediately after the scratch wound, 5, 10, 15, 20, and 25 h after scratch wound. After every image acquisition cells were placed in the CO_2 incubator.

Reporting summary. Further information on experimental design is available in the Nature Research Reporting Summary linked to this article.

Data availability

All constructs used in the present study are available upon request. Super resolution image files are too big (each file is over 1 terabyte in size) to be included in any archiving system but are available upon request. Microarray data is publicly available (https://doi.org/10.6084/m9.figshare.7621955.v1). Other data that support the findings of this study are available from the corresponding author upon reasonable request.

Abstract

Merkel cells are mechanosensory cells involved in tactile discrimination. Merkel cells have been primarily studied in the murine back skin, where they are found in specialized structures called touch domes located around primary hair follicles. Yet, little is known about the morphogenesis of Merkel cells in areas of the skin devoid of hair, such as the glabrous paw skin. Here, we describe Merkel cell formation in the glabrous paw skin during embryogenesis. We first found in the glabrous paw skin that Merkel cells were specified at E15.5, 24 hours later, compared to in the back skin. Additionally, by performing lineage-tracing experiments, we found that unlike in the back skin, SOX9(+) cells do not give rise to Merkel cells in the glabrous paw skin. Finally, we compared the transcriptomes of Merkel cells in the back and the glabrous paw skin and showed that they are similar. Genetic and transcriptome studies showed that the formation of Merkel cells in both regions was controlled by similar regulators. Among them was FGFR2, an upstream factor of MAPK signalling that was reported to have a critical function in Merkel cell formation in the back skin. Here, we showed that FGFR2 is also required for Merkel cell development in the glabrous paw skin. Taken together, our results demonstrate that Merkel cells in the murine back skin and glabrous paw skin are similar, and even though their formation is controlled by a common genetic programme, their precursor cells might differ.

KEYWORDS
FGFR2, glabrous skin, hair follicle, Merkel cells

1 | INTRODUCTION

Merkel cells were first described by Friedrich Merkel in 1875 as cells that may serve as "touch cells."[1] It took over 100 years to prove that Merkel cells have a function in skin sensation.[2] Merkel cells are mechanosensory cells, which are innervated by afferent neurons and play a key role in the tactile discrimination of the shape and texture of objects.[2,3] Functional studies in mutant mice, in which Merkel cells were not formed, have demonstrated that the animals were unable to discriminate between different textures when performing behavioural tasks.[4] In humans, Merkel cells are most abundant on the fingertips, lips and face.[5–7] In mice, they are found mainly in the back skin, paws and whiskers.[8]

Most of our knowledge about Merkel cells comes from studies focused on the murine back skin, where these cells are found in specialized structures called touch domes which are located exclusively around primary hair follicles.[9] Recently, we discovered that a subset of SOX9-expressing cells located inside of developing hair follicles are Merkel cell progenitors that give rise to Merkel cells at embryonic day (E) 14.5.[10] We also found that fibroblast growth

 © 2019 John Wiley & Sons A/S. Published by John Wiley & Sons Ltd

factor receptor 2 (FGFR2) plays an essential function in Merkel cell specification in the back skin, as loss of *Fgfr2* leads to drastic decreases in the number of Merkel cells but does not affect the formation of SOX9-positive (+) cells.[10] To further our investigations, we sought to determine whether our recent findings in the murine back skin apply to other types of skin in the mouse such as the glabrous skin. When do Merkel cells first appear in glabrous skin? Do they share common progenitors with Merkel cells in the hairy skin? How similar are the Merkel cells among these different anatomical regions? These are some of the unanswered questions we wanted to take on.

In this study, we characterized Merkel cell formation in the glabrous paw skin during embryogenesis and determined how known Merkel cell regulators in the back skin affect Merkel cell formation in the glabrous paw skin to uncover common regulators of Merkel cells.

2 | METHODS

2.1 | Mice

All mice were housed in the Center for Comparative Medicine and Surgery (CCMS) at Icahn School of Medicine at Mount Sinai (ISMMS) in accordance with the Institutional Animal Care and Use Committee (IACUC) approved protocol LA11-0020. At least three animals from independent litters were used for each analysis. $Fgfr2^{flox}$ mice were generously provided by Dr. Philippe Soriano.[11] Sox9-CreER mice were described in Ref. [12] R26-mT/mG (stock number: 007676), Atoh1-GFP (stock number: 013593), Gli1-CreER (stock number: 007913) and Krt14-Cre (stock number: 004782) mice were obtained from Jackson Laboratories. For tamoxifen treatment, pregnant females carrying Sox9-CreER; R26-mT/mG or Gli1-CreER; R26-mT/mG embryos were injected with tamoxifen (Sigma-Aldrich; St. Louis, MO) doses totalling 40 μg/g body weight at E13.5 and E14.5. Pups were collected at E17 and P0 for further analysis. Mice were genotyped mice by PCR using DNA extracted from tail skin.

2.2 | Immunofluorescence staining and microscopy

For immunofluorescence staining, tissues were collected and embedded into OCT (Tissue-Tek; Torrance, CA) and subsequently cut into 10-μm sections using a Leica Cryostat. Slides were fixed for 10 minutes in 4% paraformaldehyde (PFA; Electron Microscopy Sciences) in PBS and blocked for 1 hour at room temperature or overnight at 4°C in PBS with 1% Triton X-100, 1% BSA and 0.25% normal donkey serum (NDS). Primary antibodies were diluted in blocking solution, and incubations were carried out for one hour at room temperature or overnight at 4°C, followed by incubation in secondary antibodies for one hour at room temperature. Slides were counterstained with DAPI, mounted using antifade mounting media and then imaged using a Leica DM5500 upright slide microscope using 10x, 20x or 40x objectives.

2.3 | Antibodies

The following antibodies were used: KRT14 (generously gifted by Dr. Julie Segre of the National Human Genome Research Institute, USA, 1/20,000), KRT8 (Developmental Studies Hybridoma Bank, TROMA-1, 1/500), KRT20 (Dako, M7019, 1/70), SOX2 (Stemgent, 09–0024, 1/150), GFP (Abcam, ab13970, 1/1000), SOX9 (Abcam, ab185966, 1/500) and FGFR2 (Cell Signaling, 23328, 1/150). For immunofluorescence staining, secondary antibodies were coupled with Alexa 488, 549 or 649 from Jackson Laboratories (1/1000).

2.4 | Quantifications

Merkel cells were quantified by counting the number of KRT8(+) cells per millimetre (mm) of skin. Briefly, the length of each section was measured, and the number of positively stained cells was counted. Typical section lengths were between 7 and 14 mm, and at least 100 mm of skin was counted for each condition. A large number of Merkel cells were counted in control conditions (> 200 KRT8(+) cells), and subsequently, the number of Merkel cells in a similar length of back and paw skin was counted for the knockout condition. Comparisons and statistics were performed between matching knockout and control littermates.

2.5 | Statistics

In column bar graphs in Figure 4D and E, mean value ± one standard deviation was presented. Box-and-whisker plots show first to third quartiles around the median, with whiskers showing a 5%-95% range and outliers presented as individual data points. To determine the significance between two groups, a Mann-Whitney test was performed. For all statistical tests, $P < 0.05$ was considered for statistical significance, and furthermore, the actual *P*-values (to four decimal places) are provided in the figure legends. Significance levels were defined as $^{*}P < 0.05$, $^{**}P < 0.01$, $^{***}P < 0.001$. n.s., not significant. For statistical analyses, GraphPad Prism 5 was used.

2.6 | Fluorescence-activated cell sorting (FACS)

Interfollicular epidermis (IFE) and Merkel cells were isolated and pooled from multiple *Atoh1-GFP* newborn mice from more than 3 litters (about 50-100 newborn mice) using FACS. Briefly, P0 *Atoh1-GFP* back skins were collected and incubated for 4-6 hours in 1.26U/mL dispase (Invitrogen) at 4°C. The epidermis was then gently peeled from the underlying dermis, dissociated by 0.25% Trypsin with 1 mmol/L EDTA (Corning Cellgro; Manassas, Virginia, USA) and washed with 1x PBS. To collect glabrous skin, P0 *Atoh1-GFP* paws were collected and incubated in 1.26U/mL dispase (Invitrogen) and 0.3% type 1 collagenase (Worthington) overnight at 4°C. The paw epidermis was then separated from the dermis, dissociated in 0.25% Trypsin with 1 mmol/L EDTA (Corning Cellgro; Manassas, Virginia, USA) for 15 minutes at 37°C and washed with 1x PBS.

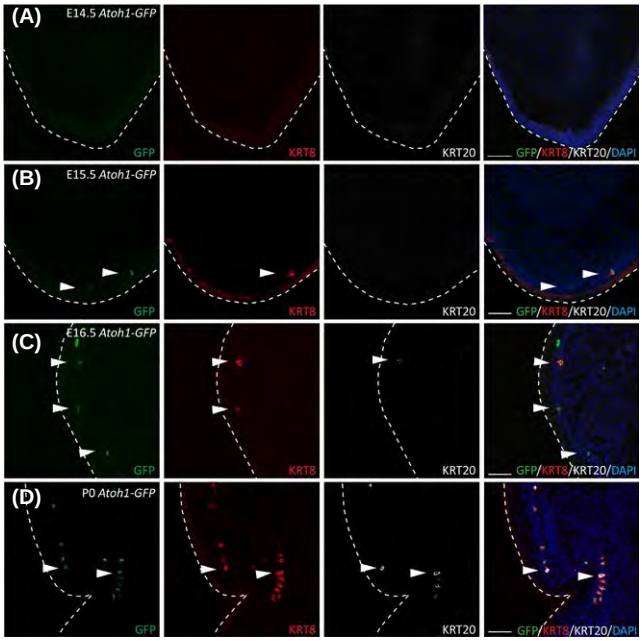

FIGURE 1 Merkel cells are formed at embryonic day 15.5 in the glabrous paw skin. (A–D) Immunofluorescence analysis of early, intermediate and late Merkel cell differentiation markers ATOH1-GFP (green), KRT8 (red) and KRT20 (white), respectively, in the glabrous paw skin of *Atoh1-GFP* mice 14.5 (A), E15.5 (B), E16.5 (C) and P0 (D). White arrows indicate Merkel cells. White dotted lines indicate the edges of the tissue. Note that ATOH1-GFP(+) and KRT8(+) Merkel cells were first observed at E15.5, and KRT20(+) Merkel cells were first observed at E16.5. Scale = 50 μm in all panels

The cell suspension was stained in HBSS + 2%FBS with 1:100 SCA1-PerCP-Cy5.5 (Biolegend) and 1:500 EPCAM-APC (Biolegend) for 20 minutes at room temperature and washed with 1x HBSS prior to cell sorting in HBSS with DAPI. IFE was sorted as ATOH1-GFP(−), EPCAM(+) and SCA1(+). Merkel cells were sorted as ATOH1-GFP(+), EPCAM(+) and SCA1(−). Note that alpha6 integrin was not used in the flow sorting scheme to isolate Merkel cells, but alpha6-integrin(+) cells were included in FACS purification of hair follicle cells.[13] All cell isolations were performed on a BD FACSAria II instrument (BD, Franklin Lakes, New Jersey, USA) in the Flow Cytometry Core Facility at ISMMS.

2.7 | RNA purification, RT-qPCR and library preparation

FACS-purified cells were collected directly into RLT Plus buffer (QIAGEN), and RNA was purified from these sorted cells with the RNeasy Plus Micro Kit (QIAGEN) according to manufacturer's instructions. To perform RT-qPCR, complimentary DNA was reverse-transcribed from total RNA using qScript cDNA SuperMix (Quanta Biosciences, Gaithersburg, Maryland, USA). Prior to library construction, sample quality was measured using an Agilent Bioanalyzer. Only samples with RNA integrity numbers > 8 were used for library preparation. Briefly, 10 ng of RNA was first reverse-transcribed and amplified using the Ovation RNA-seq System V2 (Nugen). Libraries from 100 ng of sonicated cDNA (Covaris) were then constructed using the Ovation Ultra-Low DR Multiplex system (Nugen). All RNA libraries were sequenced on an Illumina HiSeq platform at GENEWIZ.

2.8 | RNA-Seq analysis and data visualization

RNA-seq reads were aligned to the mouse reference genome (mm10) using Tophat (v2.0.13).[14] The mouse gene models of Refgene were downloaded from the UCSC genome browser (genome.uscs.edu) on 13 March 2017. FPKM (fragments per kilobase of transcript per million mapped reads) values were generated using Cufflinks (v2.2.1).[15] Lowly expressed genes (mean FPKM values < 2) were excluded from differential expression analysis. For each gene, read counts were obtained using the counts feature in the subread package (v1.4.6).[16] Differentially expressed genes were identified with absolute fold change > 5 and adjusted *P*-value < 0.01 by DESeq2.[17] The sample PCA plot was generated using the plotPCA function in DESeq2 package after a variance stabilizing transformation of the count data by the variance Stabilizing Transformation function in DESeq2 package. The heatmap was generated using the heatmap.2 function in gplots package with normalized counts from the DESeq2 package scaled by row.

2.9 | Gene ontology enrichment analysis

Significantly over-represented functional categories were identified using DAVID Bioinformatics Resources 6.8.[18] Selected gene ontology (GO) terms and KEGG pathways were considered significant with *P* values < 0.05 and are showed in Figure 4 and Table S1-S5.

2.10 | Data availability

RNA-seq data of back skin/paw glabrous skin Merkel cells and IFE at P0 were uploaded to the GEO database (GSE122598; this study). RNA-seq data of hair follicle cells at P0 were obtained from the previous publication[13] and in the GEO database (GSM3069360, GSM3069361 and GSM3069362). Additional data that support the findings of this study are available from the corresponding author upon request.

3 | RESULTS

3.1 | Merkel cells are formed at embryonic day 15.5 in the glabrous paw skin

While Merkel cells in the back skin, which contains hair follicles, have been extensively studied, little is known about the development of Merkel cells in glabrous skin, which is devoid of hair follicles. To characterize Merkel cell formation in glabrous skin, we used *Atoh1-GFP* mice, in which an enhanced green fluorescent protein (GFP) is fused to the 3′-end of the atonal homolog 1 gene (*Atoh1*).[19] We collected paws from *Atoh1-GFP* pups at embryonic day (E) 14.5, E15.5, E16.5

and postnatal day (P) 0 and performed immunofluorescence analyses of ATOH1-GFP and the keratin intermediate filaments 8 and 20 (KRT8 and KRT20, respectively) that are expressed in more mature Merkel cells.[20,21] At E14.5, when Merkel cells were already formed inside of the hair placode of the back skin,[10,21] we could not detect any ATOH1-GFP(+), KRT8(+) or KRT20(+) Merkel cells in the mouse paw (Figure 1A). At E15.5, a few ATOH1-GFP(+) and KRT8(+) Merkel cells were observed in the mouse paw (Figure 1B). At E16.5, we detected more cells positive for ATOH1-GFP and KRT8, as well as a few cells that were also positive for KRT20 (Figure 1C). At P0, the number of Merkel cells positive for ATOH1-GFP, KRT8 and KRT20 drastically increased (Figure 1D). Similar to in the back skin,[21] induction of expression of ATOH1, KRT8 and KRT20 markers was temporally regulated in the glabrous paw skin as out of more than 200 Merkel cells analysed, no KRT20(+)/KRT8(−) cells were observed and only a small number of KRT8(+)/ATOH1-GFP(−) cells were detected (Figure S1A, B). Thus, similar to in the back skin, the formation of Merkel cells in the glabrous paw skin is a temporally regulated process, although the timing of the induction of Merkel cell formation in the glabrous paw skin occurs 1 day later compared to in the back skin.

3.2 | SOX9(+) cells do not give rise to Merkel cells in the glabrous paw skin at E14.5

In the back skin, we previously found that Merkel cells formed from SOX9(+) cells present in primary hair placodes.[10] Therefore, we sought to determine whether Merkel cells in glabrous skin are also formed from SOX9(+) cells. By performing immunofluorescence studies at previously examined time points E14.5-E16.5 and P0, we observed in the glabrous paw skin that Merkel cells were not near SOX9(+) cells (Figure 2A-D), suggesting that SOX9(+) cells may not be a common precursor cell population for Merkel cells in all of the different regions of the body.

To test this hypothesis, we used *Sox9-CreER; R26-mT/mG* mice to fate map cells originating from SOX9(+) cells. We treated embryos with tamoxifen at E13.5-E14.5, when Merkel cells had not yet been specified, and collected paws and back skins at E17.5 (Figure 2E). Immunofluorescence analysis showed that GFP staining was found in approximately 85% of KRT8(+) Merkel cells in the back skin (Figure 2F, G), which is consistent with our previous report that showed that Merkel cells originate from SOX9(+) precursor cells in the back skin.[10] In contrast, KRT8(+) Merkel cells were not GFP(+) in the glabrous paw skin (Figure 2H, I; Figure S1C). In fact, GFP(+) cells were negative for E-Cadherin, a marker of epithelial cells (Figure S1D). These fate-mapping studies show that at E14.5, when SOX9(+) cells give rise to Merkel cells in the back skin, SOX9(+) cells do not give rise to Merkel cells in the glabrous paw skin.

3.3 | Differential requirement of SHH for Merkel cell formation in the back and glabrous paw skin

In the back skin, Merkel cells are located around primary hair follicles and during development originate from SOX9(+) cells located

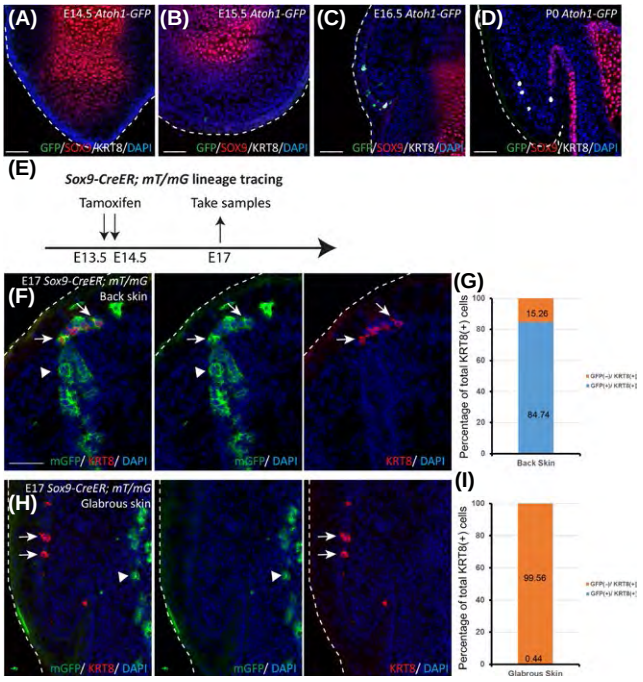

FIGURE 2 During embryogenesis, SOX9(+) cells do not give rise to Merkel cells in the glabrous paw skin at E14.5. (A–D) Immunofluorescence analysis of SOX9 (red), Merkel cell markers ATOH1-GFP (green) and KRT8 (white) at E14.5 (A), E15.5 (B), E16.5 (C) and at P0 (D) in the glabrous paw skin of *Atoh1-GFP* mice. White dotted lines indicate the edges of the tissue. Note that ATOH1-GFP(+) and KRT8(+) Merkel cells do not overlap with SOX9(+) cells. White arrows point to Merkel cells; arrow heads point to SOX9-traced cells. SOX9-traced cells are GFP(+) (green). KRT8(+) Merkel cells are stained in red. Note the overlap between SOX9 progenies and KRT8 staining. (G) Quantification of Merkel cells positive for KRT8 and GFP in *Sox9-CreER; mT/mG* back skin sections at E17. n = 6. Data are presented as a percentage of the total 401 cells quantified. The bar graph shows the percentage of KRT8(+) cells, which are co-labelled with GFP (blue) or not co-labelled with GFP (orange). (H) *Sox9-CreER; mT/mG* lineage tracing in the glabrous paw skin. White arrows point to Merkel cells; white arrow heads point to SOX9-traced cells. SOX9-traced cells are GFP(+) (green). KRT8(+) Merkel cells are stained in red. Right side panels show separated colour channels. (I). Quantification of Merkel cells positive for KRT8 and GFP in *Sox9-CreER; mT/mG* glabrous paw skin sections at E17. n = 6. Data are presented as percentages of the total 325 cells quantified. The bar graph shows the percentage of KRT8(+) cells that are co-labelled with GFP (blue) or not co-labelled with GFP (orange). White dotted lines indicate the edges of the tissue. Scale bar is 50 μm in (A-D), (F) and (H)

in developing hair follicles.[9,10] In contrast, our data showed that Merkel cells in the glabrous paw skin do not originate from SOX9(+) cells. We therefore tested whether the formation of Merkel cells in the back and glabrous skin is similarly affected in mouse mutants with impaired hair follicle formation and loss of SOX9(+) cells. SHH and Smoothened (SMO), two critical factors of the SHH signalling pathway, are essential for hair follicle formation and specification of

TABLE 1 Table of genes encoding for the critical regulator of Merkel cell formation in the back skin but not in the glabrous paw skin

Gene symbol(s)	Mouse models used to study the gene loss of function effects	Merkel cell phenotype in the back skin	Merkel cell phenotype in the glabrous skin
Shh	*Shh*$^{EGFPcre/EGFPcre}$ *Krt14-Cre; Shh*$^{flox/flox}$	Merkel cells are not formed (Perdigoto et al., 2016; Xiao et al., 2016)	Reduced number of Merkel cells (Perdigoto et al., 2016)
Smo	*Krt14-Cre; Smo*$^{flox/flox}$ *Krt5-tTA; TRE-Cre; Smo*$^{flox/flox}$	Merkel cells are not formed (Perdigoto et al., 2016; Xiao et al., 2016)	Reduced number of Merkel cells (Perdigoto et al., 2016)
Eed, Smo	*Krt14-Cre; Eed*$^{flox/flox}$; *Smo*$^{flox/flox}$	Reduced number of Merkel cells (Perdigoto et al., 2016)	Increased number of Merkel cells (Perdigoto et al., 2016)

SOX9(+) cells.[22,23] In mouse mutants that lack *Shh* or *Smo* genes in the skin epithelium, Merkel cells are not formed in the back skin.[22,23] However, in the glabrous paw skin, loss of *Shh* or *Smo* had much less of an effect on Merkel cell formation as these cells were still formed, and their total count was only slightly reduced, compared to control[23] (Table 1). This lesser effect on Merkel cell formation was also found in the glabrous paw skin when coupling the loss of *Smo* with the loss of *EED*, a component of the Polycomb repressive complex (PRC) 2 that temporally restricts Merkel cell formation.[23,24] Loss of *EED* leads to an ectopic expansion of Merkel cells in both the back and glabrous paw skin.[23,24] Concurrent loss of *EED* and *Smo* in the skin epithelium depleted Merkel cells in the back skin; however, it leads to a slight increase in the number of Merkel cells in the glabrous paw skin[23] (Table 1).

These observations encouraged us to test whether SHH-responding cells, known to serve as Merkel cell precursors in the back skin,[22] are also the precursors of Merkel cells in glabrous skin. By performing lineage-tracing experiments using *Gli1-CreER*, *mT/mG* reporter mice, we demonstrated that at E14.5, GLI1(+) cells do not give rise to Merkel cells in the glabrous paw skin (Figure S2A-C). In fact, GFP(+) cells were negative for E-cadherin, suggesting that they are not of epithelial origin (Figure S2D). Thus, during development, SHH signalling is important for Merkel cell formation in the back skin but to a lesser extent in the glabrous paw skin. Together, these results show that in the back skin, SHH signalling is required for hair follicle formation, SOX9(+) cell specification and Merkel cell development; however, in the glabrous paw skin, SHH signalling makes minor contributions to Merkel cell development.

3.4 | Transcriptome profiles of Merkel cells isolated from the back and glabrous paw skin are similar

To look further into the mechanisms of Merkel cell formation, we performed transcriptional profiling of Merkel cells isolated from the back and glabrous skin regions. By performing FACS, we purified Merkel cells from the back and glabrous paw skins of P0 *Atoh1-GFP* mice and collected IFE cells from corresponding regions. We next isolated total RNAs from these FACS-purified cells and subjected them to high-throughput RNA sequencing (RNA-seq). We also included in the analysis hair follicle cells from the back skin for comparative reference purposes.[13] Principal component analysis (PCA) of the top 5000 most variable genes (across all samples) showed that Merkel cell populations from back and glabrous paw skins clustered near each other but away from the epidermal and hair follicle populations (Figure 3A). Hierarchical clustering of the significantly differentially expressed genes between Merkel cells and IFE cells also showed that Merkel cell populations from the back skin and glabrous skin clustered together and that they are distinct from the epidermis and hair follicle cells (Figure 3B). It should be noted that since the

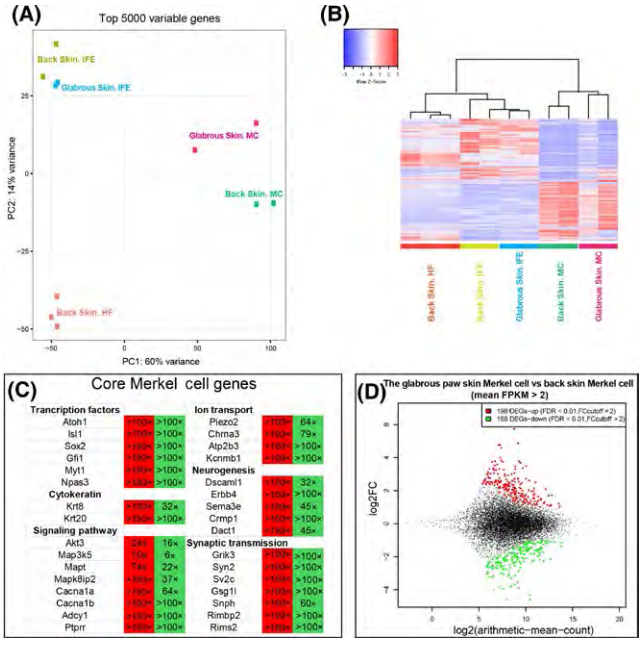

FIGURE 3 RNA-seq transcriptional profiling of Merkel cells isolated from back and glabrous paw skins revealed common core Merkel cell genes. (A) Principal component analysis based on the top 5000 most variable genes in the back skin and the glabrous paw skin. (B) Hierarchical clustering of the significantly differentially expressed genes between Merkel cells and IFE in either the back skin or glabrous paw skin (Figure S3), indicating distinct clusters of genes with either shared or unique gene expression in all isolated skin cell types. (C) List of core Merkel cell genes. Selected signature genes from the 514 genes that were commonly upregulated in Merkel cells of back and the glabrous paw skin regions, compared to IFE of the corresponding skin region and selected by these criteria, FPKM > 2, fold change > 5 and adjusted *P*-value < 0.01, are organized according to functional categories. (D) Differential expression analysis of genes expressed in Merkel cells in the glabrous paw skin vs. the back skin. Genes with mean FPKM > 2, absolute fold change > 2 and adjust *P*-value < 0.01 were considered as differentially expressed genes

Suz12	*Krt14-Cre; Suz12$^{flox/flox}$*	Increased number of Merkel cells (Dauber et al., 2016)	Increased number of Merkel cells (Dauber et al., 2016)

RNA-seq data of purified hair follicle cell populations are obtained from a previous study,[13] there could be a batch effect in the PCA and hierarchical clustering analysis.

Seeking to determine which genes are specifically expressed in the back skin and glabrous skin, we first identified 1151 genes that were significantly upregulated in Merkel cells in the back skin compared to adjacent IFE cells and 753 genes that were significantly upregulated in Merkel cells in the glabrous paw skin compared to adjacent IFE cells, by fold change > 5 and adjusted *P*-value < 0.01 (Figure S3, Table S1 and Table S2). By performing KEGG pathway analysis of genes enriched in Merkel cells of the back skin and the glabrous paw skin, we observed common enrichment for genes of the cholinergic synapse, synaptic vesicle cycle and MAPK signalling pathways (Table S1 and Table S2). Gene ontology (GO) term analysis also showed similar enrichment for genes of ion transport, nervous system development and synaptic transmission in both back skin and glabrous paw skin Merkel cell populations (Table S1 and Table S2).

In line with our PCA and hierarchical clustering analyses which showed similarity in the Merkel cell populations of the back skin and glabrous paw skin, we observed a large overlap between upregulated genes in Merkel cells in the back and glabrous paw skins, in comparison to their corresponding IFE. We identified 514 upregulated genes in common and classified them as core Merkel cell genes (Figure 3C and Table S3). Among them were *Atoh1*, *Isl1*, *Sox2*, *Krt20* and *Piezo2*, genes with known roles in Merkel cells of the back and glabrous skin[19,21,25–27] (Figure 3C and Table 2).

We next performed differential expression analysis between Merkel cells in the glabrous paw skin and those in the back skin using FDR < 0.01 and fold change cut-off > 2. The analysis showed 198 genes that were more highly expressed in glabrous paw skin Merkel cells and 168 genes that were more highly expressed in back skin Merkel cells, out of more than 11 000 genes expressed in these cells (Figure 3D; Table S4 and S5). We also observed expression of *Hox* family genes, exclusive to the back skin or glabrous paw skin. Among these were *Hoxb3*, *Hoxb7* and *Hoxb5* in back skin Merkel cells and *Hoxc9* and *Hoxc10* in glabrous paw skin Merkel cells. Additionally, KEGG pathway and GO term analyses of genes expressed higher in glabrous paw skin Merkel cells showed enrichment of genes pertaining to focal adhesion, cell division and cell cycle pathways (Table S5), while genes expressed higher in back skin Merkel cells showed enrichment of genes pertaining to focal adhesion and cell adhesion pathways (Table S4). We did not observe any enrichment for the SHH signalling pathway or its components, which could explain the differing requirement of SHH signalling of Merkel cell formation in the glabrous paw skin and the back skin. Together, this result suggests that Merkel cells in the glabrous paw skin and back skin are very similar, and differences in gene expression between these two populations are likely due to their distinct localizations within the body such as *Hox* genes.

3.5 | FGFR2 is critical for Merkel cell formation in both back and glabrous paw skin

As described above, KEGG pathway analysis of Merkel cell core genes revealed enrichment for genes of MAPK signalling pathways (Figure 4A and Table S3). Interestingly, we recently reported that FGFR2-mediated signalling is required for Merkel cell specification in the back skin,[10] and it is known that the MAPK signalling pathway is a downstream effector of FGFR2-mediated signalling.[28] To test whether FGFR2 signalling also controls Merkel cell formation in the glabrous paw skin, we analysed *Fgfr2* cKO mice in which *Fgfr2* is conditionally ablated in the skin epithelium.[10] Immunofluorescence analysis of mouse glabrous paw skin confirmed the loss of FGFR2 in P0 *Fgfr2 cKO* mice compared to control (Figure 4B) and revealed significant reductions in the numbers of KRT8(+) and KRT20(+) Merkel cells (Figure 4C-E). Thus, FGFR2-mediated signalling is required for Merkel cell formation in both back and glabrous paw skin.

4 | DISCUSSION

Merkel cells are important epidermal mechanoreceptors involved in tactile recognition of shapes and textures of objects.[4,29] In the

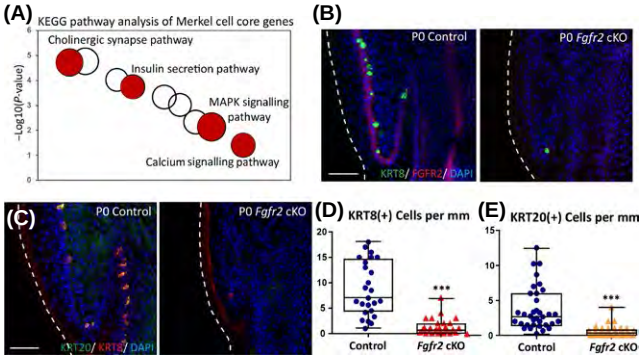

FIGURE 4 FGFR2 is critical for Merkel cell formation in the glabrous paw skin. (A) KEGG pathway analysis of Merkel cell core genes from the back skin and glabrous paw skin. body, Merkel cells are innervated by afferent neurons and located in touch-sensitive areas, which in mice are located on their back skin, whisker pads and footpads. Merkel cells in the back skin are located in touch domes around primary hair follicles and are innervated by two types of neurofilament fibres, NFH+/TrkC+ and Ret+/TrkA+ fibres.[30] In contrast to in the back skin, Merkel cells in the glabrous paw skin are mainly innervated by NFH+/TrkC+ fibres.[30]

The majority of studies on Merkel cells have been done on the murine back skin. Our recent study revealed that Merkel cells within the back skin arise from SOX9(+) precursors located in hair placodes.[10] In contrast, there is little understanding of the mechanisms that control Merkel cell formation in areas of the skin devoid of hair, such as the glabrous paw skin.

In this paper, we performed a comparative analysis of Merkel cells located in the back skin and the glabrous paw skin. Our study shows that in the glabrous paw skin, the formation of Merkel cells occurs one day later than it does in the back skin, but it follows the same maturation process characterized by progressive expression of early (*Atoh1*), mid (*Krt8*) and late (*Krt20*) differentiation markers.[21]

We performed transcriptional profiling of Merkel cells isolated from back and glabrous paw skins of newborn mice and identified that these cells share similar transcriptomes. Consistent with previous studies, among commonly expressed genes were transcription factors *Atoh1* and *Sox2*,[31,32] which have been shown to be essential for Merkel cell formation in glabrous and back skin.[19,21,26,27] In epidermal progenitors, *Atoh1* and *Sox2* are regulated by the epigenetic repressor PRC2. The loss of PRC2 by knocking out their critical components *Ezh1/2*, *Eed* or *Suz12* in the skin epithelium leads to activation of Atoh1 and Sox2 expression, which results in the formation of ectopic Merkel cells.[23,26] As in the back skin, we observed a similar phenotype in the glabrous paw PRC2-null skin epithelium.[23,24,26] To gain further insight into the general regulators of Merkel cell control, we performed KEGG pathway analysis of commonly upregulated genes and identified enrichment for genes in the MAPK signalling pathway. One of the pathways that activates the MAPK kinase cascade is the FGF signalling pathway.[28] As our recent study shows that FGFR2 is critical for Merkel cell formation in the back skin,[10] we thus examined FGFR2's role in the glabrous paw skin and demonstrated that the loss of *Fgfr2* leads to a drastic decrease in the number of Merkel cells, highlighting a general requirement for the FGFR2 signalling pathway in Merkel cell formation. Thus, Merkel cells in newborn back skin and glabrous paw skin are similar and share some common regulators that control Merkel cell formation.

Our studies also uncover the differences between Merkel cell development in both back and glabrous skin. Although SOX9(+) cells were recently shown to give rise to Merkel cells in the back skin at E14.5,[10] our fate-mapping experiments showed that SOX9(+) cells do not give rise to Merkel cell in the glabrous paw skin at a similar time point. Furthermore, we found that SHH signalling, which is essential for Merkel cell formation in the back skin,[22,23] is important but has minor roles in Merkel cell development in the glabrous skin.

How can we reconcile between these differences? In the back skin, SHH signalling is essential for proper hair follicle development, including SOX9(+) cell specification.[22,23] Because glabrous skin lacks hair follicles, the mechanisms regulating Merkel cell formation through control of hair follicle development should have no effect on Merkel cell formation in this region. Because SOX9(+) cells do not give rise to Merkel cells in the glabrous paw skin, there could be a different precursor population in this region. Alternatively, the back and glabrous paw skins might share a common Merkel cell progenitor population, with SOX9 expression within this progenitor population occurring only in the back skin. In support of the latter hypothesis, previous studies have shown that the loss of *Sox9* in the skin epithelium does not affect Merkel cell formation in the back skin, suggesting that even in this region, SOX9 is not required for Merkel cell development and serves simply as a marker.[10] Future work on uncovering a population of Merkel cell precursors in glabrous skin will reconcile these possibilities.

Future studies on the morphogenesis of Merkel cells are important not only for our understanding of the biology of the skin as a sensory organ but also for uncovering processes that lead to human pathologies. Hyper- or hypo-sensitivity to touch have long been reported in patients with diabetes, inflammation or autism.[33–36] Recent studies have shown that Merkel cells can inhibit alloknesis, a disease state where mechanical light touch stimuli provoke itching.[37] Finally, these discoveries might help us uncover which

mechanisms control Merkel cell carcinoma, a deadly skin disease with no effective treatment.[38–41]

ACKNOWLEDGEMENTS

For help, critical suggestions, reagents and experimental input, we are grateful to Dr. Ya-Chieh Hsu, Dr. Julie Segre and Sergei Ezhkov. We would like to thank Dr. Philippe Soriano for the *Fgfr2* floxed mice. We also thank the personnel of the Microscope Facility at ISMMS. Research reported in this publication was supported by the National Institute of Arthritis and Musculoskeletal and Skin Diseases of the National Institutes of Health under award number R01 AR063724 (to E.E.). We also thank the NCI P30 Cancer Center Support Grant (to E.E.) for their support, as well as the NIH/NHBLI grant, the R01HL133120 (to D.Zheng.). This content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institute of Health.

CONFLICT OF INTERESTS

The authors have declared no conflicting interests.

AUTHOR CONTRIBUTIONS

MBN, VJV, IC and EE conceived the experimental plan. MBN, VJV and IC carried out the experiments. DZ and DZ analysed RNA-seq data. MBN, IC, VP and EE wrote the manuscript with input from all authors.

Chapter 10

Isolation and Detection of G Protein-Coupled Receptor (GPCR) Heteroreceptor Complexes in Rat Brain Synaptosomal Preparation Using a Combined Brain Subcellular Fractionation/Co-immunoprecipitation (Co-IP) Procedures

Dasiel O. Borroto-Escuela, Manuel Narvaez, Martina Zannoni, Chiara Contri, Minerva Crespo-Ramírez, Michael di Palma, Patrizia Ambrogini, Daily Y. Borroto-Escuela, Ismel Brito, Mariana Pita-Rodríguez, Ismael Valladolid-Acebes, Miguel Pérez de la Mora, and Kjell Fuxe

Abstract

The isolation and characterization of GPCR heteroreceptor complexes, specially those present at the central nervous system, are of crucial relevance for the understanding of the molecular mechanisms behind several mental and neurodegenerative disorders. The existence of homo- and heteroreceptor complexes with allosteric receptor-receptor interactions increases the diversity of receptor function including recognition, trafficking, and signaling. This phenomenon increases our understanding of how brain function is altered through molecular integration of receptor signals. An alteration in specific heteroreceptor complexes or their neuronal localization is considered to have a role in the pathogenic mechanisms that lead to mental and neurological diseases, including drug addiction, depression, Parkinson's disease, and schizophrenia. Therefore, it is fundamental to understand the appropriate localization and synaptic clustering of these GPCR heteroreceptor complexes. This chapter represents a workflow for the analysis of GPCR heteroreceptor complexes by means of combined use of differential centrifugation/co-immunoprecipitation in rat brain tissue. The combination of differential centrifugation/co-immunoprecipitation allows the separation and detection of GPCR heteroreceptor complexes present at synaptic sites from those found in intracellular compartments and vesicular pools. It is a reproducible protocol and produces reliable quantitative data.

Key words G protein-coupled receptors (GPCRs), GPCR heteroreceptor complexes, Receptor-receptor interactions, Heterodimerization, Co-immunoprecipitation, Subcellular, Synaptic membrane protein, Ultracentrifugation

INFORME DE LABORES 2019

1 Introduction

Mental and neurological diseases, including drug addiction, depression, Parkinson's disease, and schizophrenia, are highly complex in their etiology. It is not surprising that the underlying pathological processes are poorly understood, and treatment possibilities are inadequate. One emerging concept is that direct physical interactions of different receptors named homo−/heteroreceptor complexes may be involved with disease onset and progression [1–3]. Among all membrane receptor complexes, the G protein-coupled receptors (GPCR) heteroreceptor complexes are of special relevance [4–8].

In the last decades, GPCR heteroreceptor complexes were demonstrated through diverse biophysical, biochemical, or microscopy-based procedures (e.g., co-immunolocalization, co-immunoprecipitation, radioligand binding, co-internalization analysis, fluorescence resonance energy transfer (FRET) or bioluminescence resonance energy transfer (BRET) methods) [9–11]. Each methodology used has provided precise and valuable information which was considered with caution in view of the limitations of the techniques. Some controversy regarding some approaches also emerged [12, 13].

In this chapter, we will describe how the combined use of brain tissue subcellular fractionation procedure and co-immunoprecipitation method may make it possible in a highly selective and sensitive assay to study and characterize also the GPCR homo- and heteroreceptor complexes, specially their existence and distribution within a subcellular compartment. Although the combined procedures of brain tissue subcellular fractionation by differential centrifugation and co-immunoprecipitation require a great deal of optimization and troubleshooting, in most cases the method allows the study of the synaptic clustering of GPCR heteroreceptor complexes in a fine-tuning manner.

2 Materials

2.1 Animals

3- to 4-week-old male Sprague Dawley rats (Scanbur, Sweden). All studies involving animals are performed in accordance with the Stockholm North Committee on Ethics of Animal Experimentation, the Swedish National Board for Laboratory Animal, and the European Communities Council Directive (Cons 123/2006/3) guidelines for accommodation and care of laboratory animals. Thus, animals are housed in standard cages with ad libitum access to food and water and maintained under controlled standard conditions (12 h dark/light cycle, 22 °C temperature, and 66% humidity).

2.2 Reagents

Protein A-immobilized agarose fast flow, 50% (v/v) (Sigma-Aldrich); TrueBlot™ anti-mouse IgG IP resin (eBioscience); Protease Inhibitor Cocktail Set III (Millipore), phosphatase inhibitors (aprotinin, β-glycerophosphate, pefabloc, leupeptin); acrylamide/bis-acrylamide (30%/0.8% w/v) (Bio-Rad); ammonium persulfate (APS) (Sigma-Aldrich); tetramethylethylenediamine (TEMED) (Sigma-Aldrich), sodium dodecyl sulfate (SDS) (Sigma-Aldrich); methanol 99.8% (Pancreac Química SL, Barcelona, Spain); Precision Plus Protein Standards (Bio-Rad); Tween 20 (Sigma-Aldrich); nonfat dry milk or bovine serum albumin (BSA) or commercial blocking buffer (e.g., Odyssey blocking buffer from LI-COR Biosciences, cat. nr. 927–40,000); SuperSignal West Pico Chemiluminescent Substrate (Thermo Fisher Scientific Inc.); BCA Protein Assay Kit (Pierce Biotechnology). *Antibodies specific for subcellular fractions*: e.g., anti-synaptophysin (Chemicon) or anti-VAMP (Stressgen) for synaptic vesicles, anti-Na^+/K^+-ATPase (Transduction Laboratories) for plasma membranes, and anti-Lactate Dehydrogenase (anti-LDH, Abcam) for cytosol. *Primary antibodies*: rabbit monoclonal anti-5HT1A (vtg544, 1 μg/mL, VTG Biosciences), goat monoclonal anti-5HT1A (ab101914, 1:500, Abcam, Sweden), rabbit monoclonal anti-5HT2A (HPA014011, 1 μg/mL; Human Atlas Project, Stockholm, Sweden), and goat monoclonal anti-5HT2A (ab140824, 1:500, Abcam, Sweden). *Secondary antibodies*: horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG (Thermo Fisher Scientific) and HRP-conjugated anti-mouse IgG TrueBlot™ (eBioscience).

2.3 Buffers

1. *Phosphate-buffered saline (PBS)*: 137 mM NaCl, 2.7 mM KCl, 1.4 mM KH_2PO_4, 17 mM Na_2HPO_4, pH 7.2.
2. *Percoll gradients*: To create a discontinuous gradient, carefully layer 2 mL of each Percoll solution in an 11 mL (16 × 100 mm) polycarbonate high-speed centrifuge tube, starting with 23% at the bottom. Prepare gradients on the day of or the day before the experiment, and keep at 4 °C until use. *23% Percoll*: 12 mL 100% Percoll and 14 mL H_2O in 26 mL 2× sucrose buffer. Adjust solutions to pH 7.4 and store up to 5 days at 4 °C. *15% Percoll*. 30 mL 23% Percoll in 16 mL 1× sucrose buffer. Adjust solutions to pH 7.4 and store up to 5 days at 4 °C. *10% Percoll*: 20 mL 15% Percoll in 10 mL 1× sucrose buffer. Adjust solutions to pH 7.4 and store up to 5 days at 4 °C. *3% Percoll*: 6 mL 10% Percoll in 14 mL 1× sucrose buffer. Adjust solutions to pH 7.4 and store up to 5 days at 4 °C.
3. *Sucrose gradients* in thin-walled ultracentrifuge tubes (ultra-clear tubes, 38.5 mL capacity, 25 × 89 mm). 7 mL 1.2 M sucrose. 6 mL 1.0 M sucrose. 6 mL 0.8 M sucrose. 6 mL 0.6 M sucrose. 6 mL 0.4 M sucrose. Prepare sucrose solutions

INFORME DE LABORES 2019

individually in Medium L, and store up to 5 days at 4 °C. On the day of experiment, layer solutions on top of each other in a thin-walled 38.5 mL, 25 × 89 mm ultracentrifuge tube, starting with 1.2 M at the bottom. Keep at 4 °C until use.

4. *Wash buffer*: 6.142 mL 2 M NaCl (122 mM final). 500 µL 1 M KCl (5 mM final). 460 µL 0.25 M NaH_2PO_4 (1.15 mM final). 4 mL 0.5 M PIPES (20 mM final). 0.1 g D-(+)-glucose (1 mg/mL final). 100 mL H_2O. Adjust to pH 6.8. Prepare fresh on the day of use and keep at 4 °C.
5. *Hypoosmotic Medium L*. 0.174 g K_2HPO_4 (1 mM final). 2 mL 0.5 M EDTA (0.1 mM final). 1 L H_2O. Adjust to pH 8.0. Store up to several months at 4 °C.
6. *Radioimmunoprecipitation assay (RIPA) lysis buffer*: 50 mM Tris–HCl, pH 7.4, 100 mM NaCl, 1% Triton X-100, 0.5% sodium deoxycholate, 0.2% SDS, and 1 mM EDTA.
7. *Sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) sample buffer*: 125 mM Tris–HCl, pH 6.8, 4% SDS, 20% glycerol, 0.004% bromophenol blue, and freshly prepared 50 mM dithiothreitol (DTT).
8. *Urea sample buffer*: 375 mM Tris–HCl, pH 6.8, 8 M Urea, 50 mM DTT, 2% SDS, 0.004% bromophenol blue.
9. *Glycine buffer*: 0.1–0.2 M glycine, pH 2.0–3.0.
10. *Electrophoresis buffer*: 25 mM Tris base, pH 8.0, 380 mM Glycine, 0.1% SDS.
11. *Anode buffer*: 300 mM Tris base, 20% methanol.
12. *Cathode buffer*: 40 mM 6-Aminocaproic acid, 20% methanol.
13. *IB blocking solution*: PBS containing 0.05% Tween 20 and 5% (w/v). You can also use the commercial blocking buffer (e.g., Odyssey blocking buffer from LI-COR Biosciences, cat. nr. 927-40000).
14. *Immunoblot (IB) washing solution*: PBS containing 0.05% Tween 20.

2.3.1 Instrumentation, Equipment, and Software

1. Rat guillotine.
2. Surgical tools for isolation of the cortex.
3. 25 and 55 mL Potter-Elvehjem homogenizers (Teflon glass).
4. High-speed centrifuge (e.g., Sorvall RC-5C with SS-34 rotor and adaptors for eight 16 × 100 mm tubes).
5. 50 mL (29 × 102 mm) polycarbonate high-speed centrifuge tubes.
6. Ultracentrifuge capable of 100,000 × *g* with swinging-bucket rotor (e.g., Beckman SW 28) and 31 mL, 25 × 89 mm, thick-walled polycarbonate ultracentrifuge tubes.

INFORME DE LABORES 2019

7. Fixed angle rotor (e.g., Beckman 70.1 Ti or 50 Ti) with 10 mL, 16 × 76 mm thick-walled polycarbonate ultracentrifuge tubes.
8. 10,000 MWCO dialysis membranes.
9. Centriprep 10 centrifugal concentrations (Millipore).
10. Mini-PROTEAN casting frame (Bio-Rad).
11. Immobilon-P transfer membrane (pore 0.45 μm, Millipore).
12. Extra thick blot paper, filter paper (Bio-Rad).
13. Western blot equipment (Bio-Rad).
14. Proper detection equipment, for instance, for Kodak Image Station 440 CF from Kodak for HRP-coupled antibodies and Odyssey from LI-COR Biosciences for infrared dye-coupled antibodies.

3 Methods

3.1 Synaptosomes Preparation (Fig. 1)

1. Sacrifice 4–8 rats weighting 200–250 g under ether anesthesia by decapitation with a guillotine. Remove carefully the brains and place in ice-cold 1× sucrose buffer.
2. Dissect quickly the brain area of interest (e.g., hippocampus, raphe nucleus, striatum (dorsal and ventral components)). Pools 4–8 are of interest together, and place in 9 mL ice-cold 1× sucrose buffer containing the Protease Inhibitor Cocktail.
3. Homogenize with the polytron for four periods of 20 s each.
4. Centrifuge the homogenate for 10 min at 1000 × *g* (3000 rpm in an SS-34 rotor) at 4 °C to remove the nucleus and tissue debris.
5. Recover the supernatant containing the membrane extracts, and carefully load 2 mL supernatant onto each of four Percoll gradients. Centrifuge gradients for exactly 5 min at 32,500 × *g* (17,250 rpm in an SS-34 rotor), 4 °C. Alternatively, the supernatant may be loaded onto a discontinuous sucrose gradient consisting of 1.2/1.0/0.8 M sucrose layers and centrifuged for 20 min at 48,200 × *g*.
6. Collect synaptosomes from the interface at 15%/23% using a Pasteur pipet. In this case, the synaptosome fraction will be collected from a discontinuous sucrose gradient consisting of 1.2/1.0/0.8 M sucrose; the synaptosomes will be collected from the interface between the 1.2 and 1.0 M sucrose layers. Synaptosomes are visible as a cloud of material concentrated at the bottom interface (15%/23% for Percoll or 1.2/1.0 M for sucrose). Use a separate Pasteur pipet to remove upper layers before collecting the synaptosome layer.

INFORME DE LABORES 2019

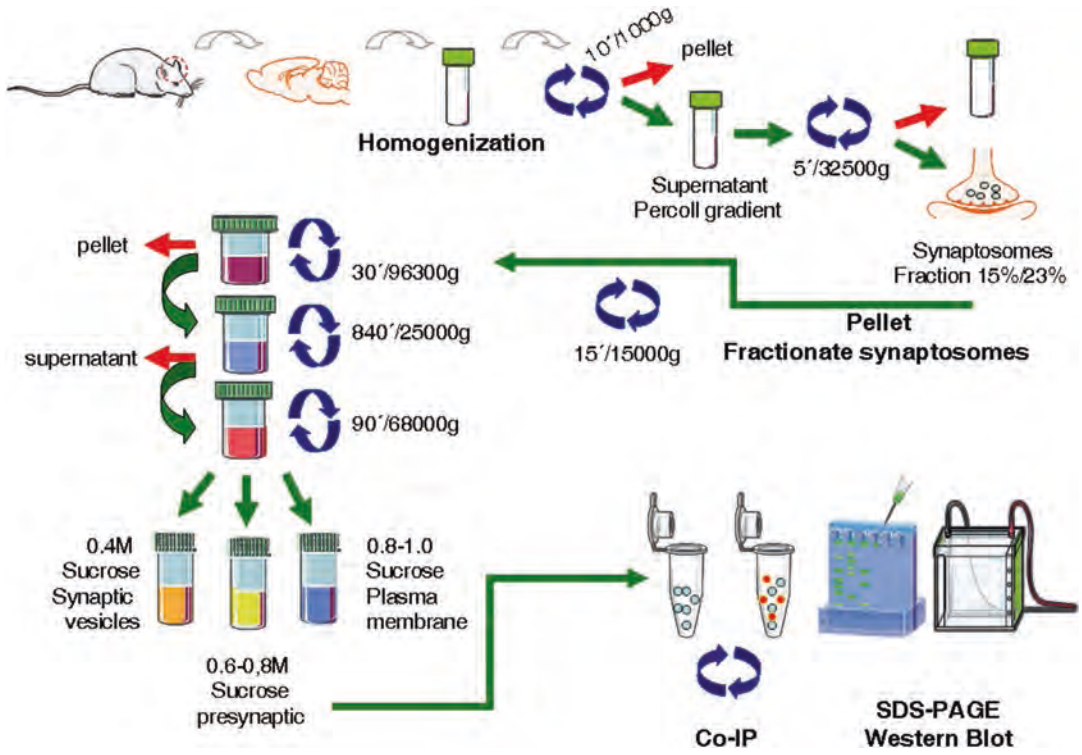

Fig. 1 Illustration of the flow chart for synaptosomes preparation and co-immunoprecipiation (Co-IP) experiment which is done using these fractions. The method is represented step by step. It includes the brain region dissection, the synaptosomes isolation, and the subcellular fraction of the synaptosomes samples by differential centrifugation and the co-immunoprecipitation, electrophoresis, and Western blot. Each of these steps is described in more details in the corresponding method section

7. Transfer the synaptosomes to a 50 mL polycarbonate centrifuge tube, and add 30 mL chilled wash buffer. Centrifuge 15 min at 15,000 × *g* (11,000 rpm in an SS-34 rotor), 4 °C.
8. Carefully discard the supernatant, and use immediately the synaptosomes pellet for fractionation (see below) or alternatively frozen down in liquid nitrogen and stored at −80 °C until use.
9. Determine the total protein content of each pellet (synaptosomes) by means of the BCA Protein Assay Kit (Pierce, USA). Adjust all membrane extracts to the same final concentration, normally between 1 and 2 mg/mL in wash buffer containing the Protease Inhibitor Cocktail.

3.2 Fractionate Synaptosomes (Fig. 1)

1. Resuspend the synaptosomes pellet (Step 8) in 12–15 mL ice-cold hypoosmotic Medium L. Save a 0.5 mL aliquot of this synaptosomal suspension for validation of the fractionation procedure.

INFORME DE LABORES 2019

2. Homogenize with the polytron for three periods of 10 s each, and then incubate suspension on ice for 15 min.
3. Repeat homogenization once more, then adjust pH to 8.0 with 1 M KOH, and incubate homogenized synaptosomal suspension on ice for another 45 min.
4. Layer, as much as you need, 5 mL synaptosomal suspension onto 5 mL of 1.0 M sucrose in Medium L in a 31 mL thick-walled polycarbonate ultracentrifuge tube.
5. Centrifuge 30 min at 96,300 × *g* (27,000 rpm in an SW 28 rotor), 0° to 4 °C. Collect the supernatant in fresh 31 mL ultracentrifuge tubes. Discard the pellet, which contain the crude synaptosomal mitochondrial fraction.
6. Cover the supernatant tubes with Parafilm and gently mix by inverting. Centrifuge 14 h at 25,000 × *g* (14,000 rpm in an SW 28 rotor), 4 °C. Collect the pellet on ice and discard the supernatant (cytosolic fraction).
7. Resuspend the pellet from Step 6 in Medium L (1.0–4.0 mL). Layer 5 mL of suspension onto separate sucrose gradients prepared in 38.5 mL thin-walled ultracentrifuge tubes. Mark phase interfaces on the tubes to facilitate recognition of the desired fractions after centrifugation.
8. Centrifuge sucrose gradients 90 min at 68,000 × *g* (23,000 rpm in an SW 28 rotor), 0° to 4 °C. Collect each fraction carefully with a Pasteur pipet. The synaptic vesicle fraction is located above the 0.4 M sucrose layer. The fraction enriched with the presynaptic plasma membrane proteins is located at the phase interfaces between 0.6/0.8, 0.8/1.0, and 1.0/1.2 M sucrose. The 0.8/1.0 M interface usually contains the purest plasma membrane fraction.
9. Transfer each fraction to a thick-walled 10 mL ultracentrifuge tube. Add Medium L to fill 3/4 of each tube. Centrifuge 45 min at 106,500 × *g* (40,000 rpm in 50 Ti rotor), 0° to 4 °C.
10. Collect each pellet, and resuspend in 0.5–1 mL of 20 mM Tris·Cl, pH 7.4, containing protease inhibitors. Store in 50–100 µL aliquots for up to several years at −20 °C.
11. Determine the total protein content of each synaptosomes fraction by means of the BCA Protein Assay Kit (Pierce, USA). Analyze aliquots containing equal amounts of protein from each fraction by SDS-PAGE. Aliquots containing 10 µg total protein should be sufficient to detect most synaptic vesicle proteins. Detect proteins of interest by immunoblotting with the appropriate specific antibodies.

3.3 Detection and Visualization of Synaptic Vesicle GPCR Heteroreceptor Complexes by Co-immuno-precipitation (A General Scheme for the Co-immuno-precipitation Procedure Is Provided in Fig. 1 (Note 1))

1. Take 0.5–1 mL membrane fraction (e.g., synaptosomes or the fraction enriched with the presynaptic plasma membrane proteins) for each antibody to be tested in the experiment.
2. Centrifuge during 30 min at 12,000 × *g* at 4 °C.
3. Resuspend pellet in 1 mL of RIPA buffer containing the Protease Inhibitor Cocktail, and homogenize using the polytron (**Note 2**).
4. Incubate during 60–120 min in constant rotation at 4 °C.
5. Centrifuge for 15 min at 10,000 × *g* at 4 °C. The membrane receptors will mainly be in the supernatant fraction.
6. Collect each supernatant in a new microcentrifuge tubes, and add 1–4 μg of the indicated primary antibody (**Note 3**).
7. Incubate the sample with the antibody overnight at 4 °C, upon constant rotation. The length of the incubation period depends on the amount of protein and affinity properties of the antibody.
8. Meanwhile prepare the Sepharose beads (**Note 4**) or use ready-to-use protein A beads (delivered as a 50% slurry). These beads are first washed three times (centrifugation after each washing step: 110 × *g*, 4 °C, 1 min) with RIPA buffer supplemented with protease and phosphatase inhibitors.
9. The washed beads are added to the incubate samples (Step 7) and incubated 2 h with rotation at 4 °C.
10. The beads are again washed. Wash the resin three times in 1 mL of ice-cold RIPA buffer (supplemented with protease and phosphatase inhibitors) by centrifuging at 10,000 × *g* for 1 min at 4 °C. In the last wash, aspirate the supernatant to dryness with a 28-gauge needle. The protein of interest should now be specifically bound to the antibody coating the beads.
11. Resuspend the resin and elute the beads. There are several possibilities: *glycine buffer elution (go to Step 5), SDS buffer elution (go to Step 6), or urea buffer elution (go to Step 7)*. In the glycine buffer, the complex is eluted from the beads by acidification using a buffer containing 0.1–0.2 M glycine, pH 2.0–3.0. The low pH of glycine weakens the interaction between the antibody and the beads. This method is advantageous as beads can be reused after removal of the glycine buffer. However, the eluted sample should be immediately neutralized with Tris, pH 8.0–8.5. On the other hand, the SDS buffer is the harshest, which will also elute non-covalently bound antibodies and antibody fragments along with the protein of interest. The Ag-Ab complex is eluted from the beads by heating or boiling samples in loading buffer with denaturant SDS. This method is advantageous because the extraction method is highly efficient and the resulting sample is more concentrated. The urea elu-

tion is advantageous for mass spectrometry because the sample can be digested by proteolytic enzymes.

12. Elute the beads (50 µL) with 3 × 50 µL 0.2 M glycine pH 2.6 (1:1) by incubating the sample for 10 min with frequent agitation before gentle centrifugation. Pool the eluate and neutralize by adding equal volume of Tris pH 8.0. Neutralize the beads by washing 2× with 150 µL lysis buffer (without detergent), and pool with eluate. Run the samples on SDS-PAGE (see below Step 8).
13. Elute 50 µL of beads by heating in 50 µL of 2× SDS loading buffer without DTT for 10 min at 50 °C. Pellet beads, transfer supernatant to a new tube, and add DTT at 100 mM (elution 1). Add 50 µL 2× SDS buffer with DTT to pelleted beads (elution 2). Boil the eluted samples for 5 min, and analyze content of the sample by SDS-PAGE and Western blot (see below Step 8).
14. Wash beads with pre-urea wash buffer (50 mM Tris pH 8.5, 1 mM EGTA, 75 mM KCl). Remove all residual supernatant. Add 2–5 volumes urea elution buffer (6–8 M Urea, 20 mM Tris pH 7.5, and 100 mM NaCl), and rotate for 30 min at room temperature with frequent agitation before gentle centrifugation. Repeat this process at least twice more to ensure that the entire captured complex has been released from the beads. Pellet beads and remove urea to a new tube. Run the samples on SDS-PAGE (see below Step 8).
15. Finally, when the receptors are eluted from the beads, standard SDS-PAGE can be performed to separate the receptors according to their molecular weight. Prepare samples for SDS-PAGE. Load the mini-PROTEAN tetra cell with electrophoresis buffer. Load protein marker and samples into the gel wells.
16. Run the gels at 75 V until samples reach the separating gel, and then increase voltage until 150 V. Stop SDS-PAGE running when the downmost band of the protein marker reaches the foot line of the glass plate.
17. Following electrophoresis, separate glass plates, recover the gel, and equilibrate it in anode buffer for 5 min.
18. Cut two immunoblot thick filter papers in 6.25 × 9.25 cm sheet. Soak one of them in anode buffer and the other in cathode buffer.
19. Cut Immobilon-P transfer membranes in 9 cm × 6 cm sheets. Completely soak membranes in methanol for 3 s to activate them and finally equilibrate in anode buffer.
20. Prepare the Western blot sandwich by placing (a) the anode buffer pre-soaked sheet of filter paper onto the anode cassette; (b) the anode buffer pre-wetted transfer membrane on top of

the filter paper; (c) the anode buffer equilibrated gel on top of the transfer membrane, aligning the gel on the center of the membrane; and finally (d) the other cathode buffer pre-soaked extra thick filter paper on top of the gel.

21. Roll a plastic pipet over the surface of the filter paper in both directions to eliminate air bubbles and to ensure complete contact between polyacrylamide gel and the transfer membrane.
22. Carefully place the cathode top onto the cassette.
23. Turn on the power and transfer mini gels for 30 min at 25 V.
24. Following transfer, discard filter papers and polyacrylamide gel.
25. Block transfer membrane in IB blocking solution for 30 min at room temperature with continuous shacking.
26. Incubate the membrane overnight at 4 °C with the indicated primary antibody diluted in IB blocking solution with continuous shaking. You can also use the commercial blocking buffer (e.g., Odyssey blocking buffer from LI-COR Biosciences, cat. nr. 927–40,000).
27. Make three washes of 10 min with IB washing solution to eliminate unbound primary antibody.
28. Incubate with the indicated secondary antibody for 90 min at room temperature in continuous shaking. For instance, the horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG (Thermo Fisher Scientific), HRP-conjugated anti-mouse IgG TrueBlot™ (eBioscience), or Odyssey for infrared dye-coupled antibodies from LI-COR.
29. Make three washes of 10 min with IB washing solution to eliminate unbound secondary antibody.
30. If using the horseradish peroxidase (HRP)-conjugated antibodies, incubate membrane with SuperSignal West Pico Chemiluminescent Substrate (prepare the mix following the proportion 1:1 of solution A and B provided by the manufacturer in dark conditions).
31. Develop membrane in, for instance, Kodak Image Station 440 CF from Kodak for HRP-coupled antibodies and Odyssey from LI-COR Biosciences for infrared dye-coupled antibodies.

4 Notes

1. There are a few different methods to co-immunoprecipitate GPCRs. One approach consists in the pre-mixture of the pri-

mary antibody with your membrane fraction sample, followed by addition of protein A/G support. This method yields high purity of receptor; however, the antibodies are also co-eluted with receptor of interest which sometimes creates difficulties in Western blot detection. The other approach is to bind the primary antibody that recognizes one of the protomers of interest to the protein A/G beads and then mix with the antigen. This method gives lesser yield than the first one but avoids the problem of co-elution of antibodies. Herein we will describe the first approach.

2. There are a lot of possibilities concerning detergent choice for the solubilization of membrane receptors. For instance, CHAPS buffer (30 mM Tris–HCl pH 7.5; 150 mM NaCl; 1% CHAPS), TNT buffer (20 mM Tris/HCl pH 7.5; 200 mM NaCl; 0.1% Tween 20), NP-40 buffer (0.5% NP-40; 140 mM NaCl; 1.5 mM $MgCl_2$; 10 mM Tris HCl pH 7.5), and Triton X-100 buffer (10% glycerol; 1% Triton X-100; 160 mM NaCl; 50 mM Tris HCl pH 7.5; 1 mM EDTA; 1 mM EGTA). So far, for GPCR the RIPA buffer (150 mM NaCl; 50 mM Tris HCl pH 7.5; 1% NP-40; 0.1% SDS; 0.5% deoxycholic acid) seemed to be the optimal choice, because it gave the best signal. The RIPA lyses buffer is based on moderate concentrations of the nonionic detergent NP-40 that will disrupt the integrity of the cell membrane, causing the extraction of membrane proteins in their native form. The buffer also contains a low concentration of the harsh denaturing anionic detergent SDS and ionic detergent sodium deoxycholate. SDS and sodium deoxycholate will help to disrupt the membrane, resulting in a higher yield of extracted membrane proteins. The concentration of these two is however quite low and will not be able to disrupt the protein–protein interactions. In addition, the detergent digitonin (0.1%) can also be added to optimize the solubilization of the membrane receptors.
3. Typically in a pilot experiment, a fixed amount of protein is precipitated by increasing amounts of antibody. Check the antibody datasheet for recommended antibody concentration. As a guideline use 1–5 μL polyclonal antiserum, 1 μg affinity purified polyclonal antibody, 0.2–1 μL ascites fluid (monoclonal antibody), or 20–100 μL culture supernatant (monoclonal antibody).
4. If using a monoclonal antibody choose protein G-coupled Sepharose beads. If using a polyclonal antibody, protein A-coupled Sepharose beads are usually a better option. If the beads come as a powder, incubate 100 mg of beads in 1 mL 0.1 M PBS, wash for 1 h so they swell up, and then centrifuge, remove the supernatant, and discard. Add 1 mL PBS 0.1% BSA, mix for 1 h using an Eppendorf rotator and rinse twice in

PBS. Remove the supernatant and add 400 μL of buffer made with protease inhibitors. The slurry is now ready for use. It can be stored at 4 °C for a few days. You can also buy pre-swollen beads as slurry ready for use. If use IgM antibodies, do not use protein A- or protein G-conjugated beads. Use, instead, anti-IgM coupled protein A or protein G beads. The IgM will bind to the beads by binding to the anti-IgM antibody.

Neurospora crassa NADPH Oxidase NOX-1 Is Localized in the Vacuolar System and the Plasma Membrane

The NADPH oxidases (NOX) catalyze the production of superoxide by transferring electrons from NADPH to O_2, in a regulated manner. In *Neurospora crassa* NOX-1 is required for normal growth of hyphae, development of aerial mycelium and asexual spores, and it is essential for sexual differentiation and cell-cell fusion. Determining the subcellular localization of NOX-1 is a critical step in understanding the mechanisms by which this enzyme can regulate all these different processes. Using fully functional versions of NOX-1 tagged with mCherry, we show that in growing hyphae NOX-1 shows only a minor association with the endoplasmic reticulum (ER) markers Ca^{2+}-ATPase NCA-1 and an ER lumen-targeted GFP. Likewise, NOX-1 shows minor co-localization with early endosomes labeled with YPT-52, a GTPase of the Rab5 family. In contrast, NOX-1 shows extensive co-localization with two independent markers of the entire vacuolar system; the vacuolar ATPase subunit VMA-1 and the fluorescent molecule carboxy-DFFDA. In addition, part of NOX-1 was detected at the plasma membrane. The NOX-1 regulatory subunit NOR-1 displays a very different pattern of localization, showing a fine granular distribution along the entire hypha and some accumulation at the hyphal tip. In older hyphal regions, germinating conidia, and conidiophores it forms larger and discrete puncta some of which appear localized at the plasma membrane and septa. Notably, co-localization of NOX-1 and NOR-1 was mainly observed under conidial cell-cell fusion conditions in discrete vesicular structures. NOX functions in fungi have been evaluated mainly in mutants that completely lacked this protein, also eliminating interactions between hyphal growth regulatory proteins NOR-1, the GTPase RAC-1 and the scaffold protein BEM-1. To dissect NOX-1 roles as scaffold and as ROS-producing enzyme, we analyzed the function of NOX-1::mCherry proteins carrying proline 382 by histidine (P382H) or cysteine 524 by arginine (C524R) substitutions, predicted to only affect NADPH-binding. Without notably affecting NOX-1 localization or protein levels, each of these substitutions resulted in lack of function phenotypes, indicating that NOX-1 multiple functions are all dependent on its oxidase activity. Our results open new interpretations to possible NOX functions, as components of the fungal vacuolar system and the plasma membrane, as well as to new vacuolar functions.

INTRODUCTION

Many years ago we proposed reactive oxygen species (ROS) as signaling molecules and regulators of cell differentiation (Hansberg and Aguirre, 1990; Aguirre et al., 2005). The existence of NADPH oxidase (NOX) enzymes, capable of producing ROS in a highly regulated fashion, became particularly interesting to us in this context. NOX2 (gp91*phox*), the catalytic component of the first and most studied NOX was reported as a novel cytochrome *b*558 in phagocytic vacuoles of human granulocytes (Segal and Jones, 1978), where phagocytosis is associated with the production of superoxide and other derived ROS, necessary for the efficient killing of invading pathogens. Defects in NOX components cause the immunodeficiency syndrome called granulomatous disease or CGD (Babior, 1995). Later, it was found that NOX2 was part of a larger family of enzymes that were ubiquitous in eukaryotic cells, where they were related not only to innate immunity but also to other processes such as modifications of the extracellular matrix, cell-cell signaling, development, and morphogenesis (Lambeth et al., 2000; Lara-Ortiz, 2004; Aguirre and Lambeth, 2010).

We reported the presence of three different NOX subfamilies in fungi and the Amoebozoa, and demonstrated that NOX enzymes were essential for ROS production and sexual development in the Ascomycetes *Aspergillus nidulans* (Lara-Ortiz et al., 2003; Aguirre et al., 2005), *Neurospora crassa* (Cano-Dominguez et al., 2008), and *Sordaria macrospora* (Dirschnabel et al., 2014). Independently, Malagnac et al. (2004) found that in *Podospora anserina* PaNox1 and PaNox2 were needed for sexual development and ascospore germination, respectively (Malagnac et al., 2004). Since then, fungal NOX enzymes have been linked to other critical functions such as growth, asexual development, cell-cell fusion (Cano-Dominguez et al., 2008; Fu et al., 2011; Read et al., 2012; Roca et al., 2012; Dirschnabel et al., 2014), pathogenicity (Egan et al., 2007; Segmuller et al., 2008; Kim et al., 2011; Schurmann et al., 2013; Yang and Chung, 2013; Zhang et al., 2016; Rossi et al., 2017; Zhou et al., 2017), endosymbiosis (Tanaka et al., 2006), and the asexual reproduction induced by injury in *Trichoderma atroviride* (Hernandez-Onate et al., 2012). More recently the functions of other NOX enzymes, originally considered as ferric reductases, have been reported in *Saccharomyces cerevisiae* (Rinnerthaler et al., 2012) and *Candida albicans* (Rossi et al., 2017), while bioinformatic analysis and *in vitro* experiments suggest the presence of NOX enzymes in prokaryotes (Hajjar et al., 2017). Such ubiquity of NOX enzymes supports the idea that the controlled production of ROS as signaling molecules appeared early in life evolution as an important mechanism to regulate cell physiology and differentiation.

In mammalian phagocytic cells part of NOX2 is localized in the plasma membrane, where it interacts with subunits p22*phox*, p40*phox*, p47*phox*, p67*phox*, and the GTPase Rac1 for its activation [reviewed in Aguirre and Lambeth (2010)]. Fungal A and B NOX subfamilies belong to the NOX2 family (Lara-Ortiz et al., 2003; Aguirre et al., 2005), and interact with equivalent subunits. Indeed, p67*phox* homolog NoxR interacts with RacA (Takemoto et al., 2006), and together with p22*phox* homolog NoxD (Lacaze et al., 2015; Siegmund et al., 2015) are required for NOX functions (Takemoto et al., 2006; Cano-Dominguez et al., 2008). Membrane proteins of the tetraspanin family have also been linked to NOX function (Lambou et al., 2008; Schurmann et al., 2013; Siegmund et al., 2013; Lacaze et al., 2015; Zhao et al., 2016) and suggested to play roles analogous to p22*phox* for NoxB family members. Finally, it has been proposed that fungal Bem1 proteins play roles analogous to animal p40*phox* and p47*phox* (Takemoto et al., 2011).

Although little is known about how NOX and ROS can regulate so many seemingly different functions in fungi, some NOX functions have been related to actin organization and calcium signaling. In yeast, mutants lacking the NOX Yno1p are hypersensitive to drugs that inhibit F-actin nucleation and elongation, and this phenotype is rescued by non-toxic concentrations of H_2O_2, suggesting that Yno1p is necessary for proper F-actin function (Rinnerthaler et al., 2012). In the phytopathogen *Magnaporthe grisea Δnox1* and *Δnox2* mutants are able to differentiate the leaf penetration structure called appressorium, but fail to penetrate the plant cuticle (Egan et al., 2007). Nox2 and NoxR are required to organize a septin ring at the base of the appressorium pore, which in turn is necessary for the assembly of a toroidal F-actin network at the point of penetration peg emergence, while Nox1 is needed to maintain the cortical F-actin network (Ryder et al., 2013). A similar situation occurs in the fungus *Verticillium dahlia*, which only infects plant roots using a structure called hyphopodium, from which a penetration peg develops. Mutants lacking NOX VdNoxB are impaired in the formation of a septin ring that partitions the hyphopodium and the invasive hyphae, which is critical for the secretion of effector proteins (Zhou et al., 2017). Moreover, tetraspanin VdPls1 and NOX VdNoxB are specifically expressed in hyphopodia, where they colocalize and are necessary for ROS production and the development of the penetration peg. The nuclear targeting of the calcium-regulated transcription factor VdCrz1, which normally occurs in hyphopodia, was prevented in mutants lacking VdPls1 or VdNoxB, linking NOX function and calcium signaling in this process (Zhao et al., 2016).

Neurospora crassa is a particularly interesting model to study NOX function, as it contains two NOX enzymes (NOX-1 and NOX-2), both requiring the regulatory subunit encoded by *nor-1* (NCU07850). While *nox-2* (NCU10775) elimination only affects ascospore germination, *nox-1* (NCU02110) deletion has more pleitropic effects in this fungus than in any other fungus studied. Indeed, NOX-1 is required for normal growth of vegetative hyphae, growth of the aerial mycelium and conidia production, and it is essential for sexual differentiation and hyphal fusion (Cano-Dominguez et al., 2008; Read et al., 2012). To understand how NOX-1 might regulate so many different cellular processes, it is critical to know the subcellular localization of this enzyme. Here we compare the subcellular localization of NOX-1 and its regulatory subunit NOR-1 during different conditions of growth and development and provide genetic evidence supporting that all critical NOX-1 functions require its oxidase activity.

MATERIALS AND METHODS

Strains, Media, Growth Conditions, and Phenotypic Characterization

Neurospora crassa strains used in this work are listed in **Table S1**. All strains were grown on Vogel's minimal medium (VMM) solidified with 1.8% agar at 30°C (Davies and deSerres, 1970). For histidine auxotrophic strains, VMM was supplemented with 0.002% of L-histidine. To determine the production of conidia, 1×10^4 conidia were inoculated on borosilicate tubes containing 3 mL of solid VMM and incubated at 30°C during 3 days in the dark plus 2 days at 25°C in the light. Conidia from these tube cultures were collected with 1 mL of sterile water, diluted and counted using a Neubauer chamber. For radial growth analysis, 1×10^3 conidia were inoculated on the center of a Petri dish containing Vogel's solid minimal medium. Radial growth was measure after 24 h at 30°C and plates were photographed. For observation of conidial anastomosis tube (CAT) formation and fusion, 8×10^6 conidia were inoculated on solid MMV medium using a glass handle, and incubated at 37°C for 4–5 h. An agar block sectioned from these cultures was directly observed under the microscope. To induce sexual crosses, conidia were inoculated on synthetic crossing medium and incubated for 6 days at 25°C in the light (Westergaard and Mitchell, 1974). After that time, a conidial suspension from the opposite mating type was laid over this culture. To follow fruiting body primordia (protoperithecia) development, 1×10^3 conidia were used to initiate cultures according to the method of Bistis (Bistis, 1983; Cano-Dominguez et al., 2008).

Plasmids Construction

The list of plasmids obtained in this work is given in **Table S2**. To construct plasmid pNCNOX-1::mCherry4, *nox-1* (NCU02110) ORF (1659 pb) was amplified using *N. crassa* genomic DNA as template and primers NOX-1 XbaIF2 and NOX-1 PacIR2 (**Table S3**). The generated PCR product fragment was cloned as a *Xba*I/*Pac*I fragment into plasmid pJV15-2 (Verdin et al., 2009). Plasmids pNCNOX-1P382H and pNCNOX-1C524R were generated using In-Fusion® HD Cloning Kit-Clonetech and primers Nox-1 P382HF and Nox-1 P382HR for pNCNOX-1P382H, and Nox-1 C524RF and Nox-1 C524RR for pNCNOX-1C524R. These primers contain point mutations and 15 pb overlap with adjoining fragments. Plasmid pNCNOX-1::mCherry4 was used as template for the In-Fusion® reaction. To replace *ccg-1* promoter by *nox-1* native promoter in pNCNOX-1::mCherry4, we used genomic DNA to amplify a 1226 pb upstream of *nox-1* ORF with primes NOX-1PROM NATF and PromNatR. Then, we amplified the host plasmid pNCNOX-1::mCherry4 using primers PNC-NOX-1mCherry PromNatF and PNC-NOX-1mCherry PromNatR. The amplified host plasmid lacks the *ccg-1* promoter and contains 15 pb overlap with the 1226 pb *nox-1* promoter region. In the last step, we used In-Fusion® HD Cloning Kit-Clonetech to perform the ligation. To fuse NOR-1 to GFP, we amplified *nor-1* (NCU07850) ORF as a 1893 pb fragment, using primers NOR-1BAMHIUP and NOR-1PacILOW and genomic DNA as template. This PCR product was purified and cloned into pGEM®-T Easy Vector (Promega, Madison, WI) to yield plasmid pGemNOR-1-2. A *nor-1 PacI-BamHI* fragment obtained from pGemNOR-1-2 was cloned into plasmid pMF272 (Freitag et al., 2004), digested with *XbaI*/*PacI*, to generate pNCNOR-1::GFP18.

Neurospora crassa Transformation

Conidia were collected from VMM slant cultures using cold sterile water. After determining their concentration, 1.25×10^8 conidia were collected by centrifugation and washed two times with 500 μL of 1 M cold sorbitol and finally resuspended in 40 μL of the same solution. This spore suspension was incubated with DNA (plasmids or PCR products, during 30 min at 4°C) and electroporated using the Gene Pulser II and Pulser Controller II (Bio-Rad, Hercules, CA) set to 1.5 kV, 600 Ω, and 2.5 μF, as reported (Colot et al., 2006). After electroporation, 960 μL of 1 M cold sorbitol were added, mixed with 25 mL of recovery solution (liquid Vogel's medium) and incubated at 30°C and 100 RPM, for 2 h. This solution was mixed with 25 mL of regeneration agar (Vogel's medium with 1 M sorbitol, 2% L-sorbose, 0.05% glucose, 0.05% fructose, and 1% agar) and plated immediately on solid CA medium (2% L-sorbose, 0.05% glucose, 0.05% fructose in Vogel media, and 1% agar) containing hygromycin (200 μg/mL) or phleomycin (80 μg/mL) (Colot et al., 2006). Transformants were purified to obtain homokaryotic strains through three monosporic passes on CA medium plus hygromycin (200 μg/mL) or phleomycin (80 μg/mL).

Heterokaryon Formation

To observe hypha with two proteins labeled with different fluorophores, we constructed heterokaryons using strains with the same mating types. We inoculated 4×10^6 conidia of each strain on a solid VMM. Cultures were incubated at 37°C for 4–5 h to induce CAT fusion. Cell fusion was verified under epifluorescence microscopy and then agar blocks were transferred to solid VMM and incubated for 12 h at 30°C. The margins of the colony were used to detect hyphae expressing both markers and observed under confocal microscopy.

Microscopy

Primordia (protoperithecia) and mature sexual fruiting bodies (perithecia) were photographed using a Nikon stereoscopic microscope. Live-cell imaging was carried out using the "inverted agar block" method (Hickey et al., 2002) and a Zeiss LSM-800-Inverted Laser Scanning Confocal Microscope with a Plan-Apochromatic 63x/1.4 oil immersion objective and 488 and 561 nm laser lines, or a Zeiss LSM-800-Inverted Laser Scanning Confocal Microscope with a 30°C temperature chamber and the same parameters. Time-lapse images were recorded simultaneously by bright field microscopy and fluorescence confocal microscopy. The images were processed using ZEN 2012 (Carl Zeiss, Jena, Germany) software. Latrunculin A (Lat A) (Tocris Bioscience, Bristol, UK: 100 μg) was use to inhibit actin polymerization and endocytosis. A 2 μg/μL stock solution in DMSO was diluted with VMM to a final 20 μg/mL working concentration. Fifty microliter of this solution were placed onto a coverslip and mycelium on an agar block was placed in contact

with the latrunculin. After 10 min, the sample was observed using confocal microscopy. Oregon Green 488 carboxylic acid diacetate (carboxy-DFFDA; Molecular Probes) was used to visualize the vacuolar system. A 1 mM stock solution in DMSO was diluted with VMM to a final 10 μM concentration. Fifty microliter of this solution were placed onto a coverslip and conidia or mycelium on agar blocks were placed in contact with the dye. The sample was observed immediately in the Zeiss LSM-800 Confocal Microscope equipped with a 30°C temperature chamber.

RESULTS

NOX-1::mCherry Expressed From *ccg*-1 Promoter Fully Complements *Δnox-1* Mutant Multiple Defects

To determine NOX-1 subcellular localization we decided to use fluorescent protein mCherry, an improved version of mRFP1, showing higher photostability and pH resistance (Shaner et al., 2004). First, we generated plasmid pNCNOX-1::mCherry4, which contains a *nox-1::mCherry* gene fusion under the control the *ccg-1* constitutive promoter and allows integration at the *his-3* locus. We used this plasmid to transform strain *Δnox-1 his-3*, and four His-3$^+$ transformants were analyzed by PCR to confirm the presence of this plasmid at the *his-3* locus. Strains *Δnox-1 nox-1::mCherry d* and *e* were selected for further experiments (**Figure S1**). As reported before (Cano-Dominguez et al., 2008), *Δnox-1* mutants showed a severe decrease in aerial mycelium growth and conidiation, reduced radial growth and were unable to develop perithecia, with these phenotypes being somewhat enhanced by the presence of *his-3* mutation (**Figures S2A–E**). The *nox-1::mCherry* allele was able to fully complement the defects in aerial mycelium growth and conidiation (**Figures S2A,B)** and restored radial growth (**Figures S2C,D**, **S7D**). Moreover, *Δnox-1* complemented strains were able to produce protoperithecia (not shown) that were competent for fertilization and able to develop mature perithecia (**Figure S2E**), containing viable ascospores (not shown).

When inoculated at high density, conidia from *N. crassa* and other fungi develop specialized structures, called conidial anastomosis tubes or CATs, for cell-cell fusion (Fischer and Glass, 2019). Although *Δnox-1* mutants differentiate CAT structures, these cannot undergo cell-cell fusion (Cano-Dominguez et al., 2008; Read et al., 2012). We used confocal microscopy to determine NOX-1::mCherry localization during germination, and to assess if this allele complemented *Δnox-1* cell fusion defects. Results in **Figure 1A** show that in germinating conidia the NOX-1::mCherry signal, largely absent from the hyphal tip, was localized in discrete round and tubular structures behind the hyphal tip, which moved very fast and showed very dynamic shape changes. CATs from strain *Δnox-1 nox-1::mCherry* were competent for cell-cell fusion (**Figure 1B)** and NOX-1::mCherry labeled structures were exchanged freely between the fusion partners (**Video S1**). This shows that NOX-1::mCherry expressed from *ccg*-1 promoter complements all *Δnox-1* mutant phenotypes, and its localization in mobile globular and filamentous structures during conidial germination.

In Growing Hyphae NOX-1 Is Localized in Pleomorphic Structures Consistent With the Morphology of the Entire Vacuolar System

Having shown NOX-1::mCherry fusion functionality, we next determined NOX-1 localization during hyphal growth using *in vivo* confocal microscopy. **Figure 2** shows the reconstruction of a single hyphae in which three major characteristic regions can be distinguished; the actively growing tip, a central region and an older region that contains large spherical vacuoles. In contrast to the simpler pattern observed in germinated conidia (**Figures 1A,B**), NOX-1::mCherry signal displayed a highly differentiated pattern within these three regions. First, mCherry signal was very low closer to the hyphal tip and then gradually increased behind the tip, defining small round structures, some presenting u- or o-ring shapes (white arrow in **Figure 2B**). Second, the intensity and density of fluorescent signal increased toward the second hyphal segment up to the first septum, displaying a well-defined tubular network. Third, a more discrete pattern, including large round structures, was observed in the older region of the hyphae, where proteins that belong to the vacuolar system such as CAX, NCA-2, and some times VMA-1 have been localized (Bowman et al., 2009). Considering that the pattern of these three regions is notably similar to the one recently reported for the entire vacuolar system in *N. crassa* (Bowman et al., 2015), we also delimited them as the prevacuolar compartment, tubular vacuolar network and large spherical vacuolar regions, respectively (**Figure 2A**). In turn, the prevacuolar region was divided in regions I, II, III, and IV (**Figure 2B**), according to the population of vacuoles, distance from the hyphal tip and Bowman's nomenclature (Bowman et al., 2015). **Figure 2B** shows an enlarged image of the prevacuolar region shown in **Figure 2A**. As indicated before, NOX-1::mCherry signal was low in regions I and II. In zone III it became more visible, being located in small structures and some rings or u-shaped structures (**Figure 2B** and **Video S2**). Zone IV shows a transition between the morphology of zone III and the beginning of the dense network of interconnected filaments that extends backwards until the position of the first septum. These results are consistent with NOX-1 being localized in the entire vacuolar system.

NOX-1 Shows Minor Co-localization With Endoplasmic Reticulum and Endosome Markers

In filamentous fungi *P. anserina* (Lacaze et al., 2015) and *Botrytis cinerea* (Siegmund et al., 2013, 2015), NOX-1 has been detected mainly in the ER and in vesicles proposed to derive from the ER (Schurmann et al., 2013; Siegmund et al., 2013, 2015; Lacaze et al., 2015). To explore this in *N. crassa*, we performed co-localization experiments following NOX-1::mCherry and NCA-1, a homolog of the SERCA-type Ca^{2+}-ATPase, as an ER marker (Bowman et al., 2009), tagged with GFP. Heterokaryotic mycelia from NCA-1::GFP and NOX-1::mCherry strains were analyzed by confocal microscopy. Results in **Figure 3A** show that, as reported before, NCA-1 is

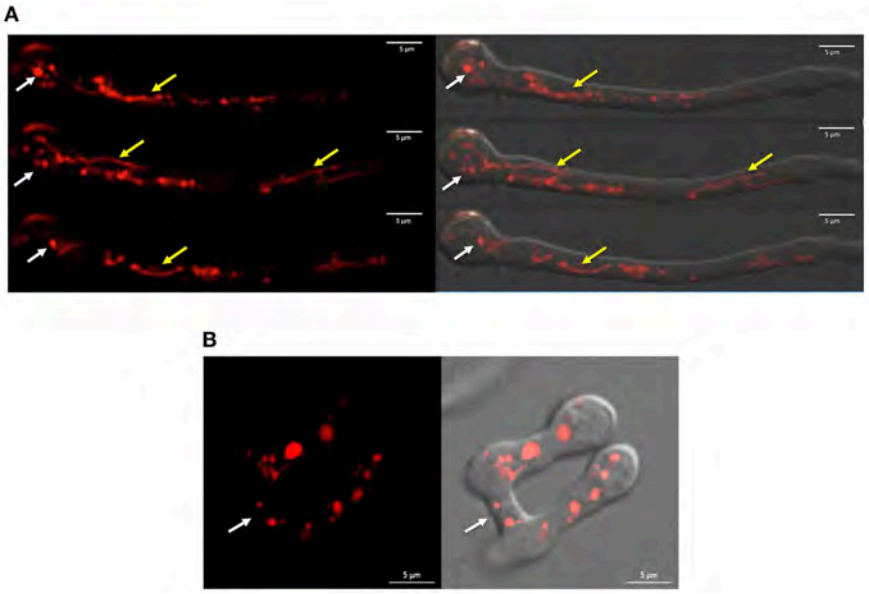

FIGURE 1 | NOX-1::mCherry expressed from *ccg*-1 promoter is localized in discrete compartments and complements *Δnox-1* cell fusion defects. **(A)** Conidia from strain *Δnox-1 nox-1-mCherry e* were induced to germinate and observed using confocal microscopy. NOX-1::mCherry is localized in round (white arrows) and tubular (yellow arrows) organelles. Images belong to a series of frames from a movie (not shown). **(B)** Conidia from strain *Δnox-1 nox-1-mCherry e* were induced to develop CATs and observed using confocal microscopy. Figures represent still images from **Video S1**. Left panel shows NOX-1-mCherry fluorescence signal of two conidia with CATs fused at the indicated point (white arrow). The right panel shows the same image merged to the corresponding bright field image.

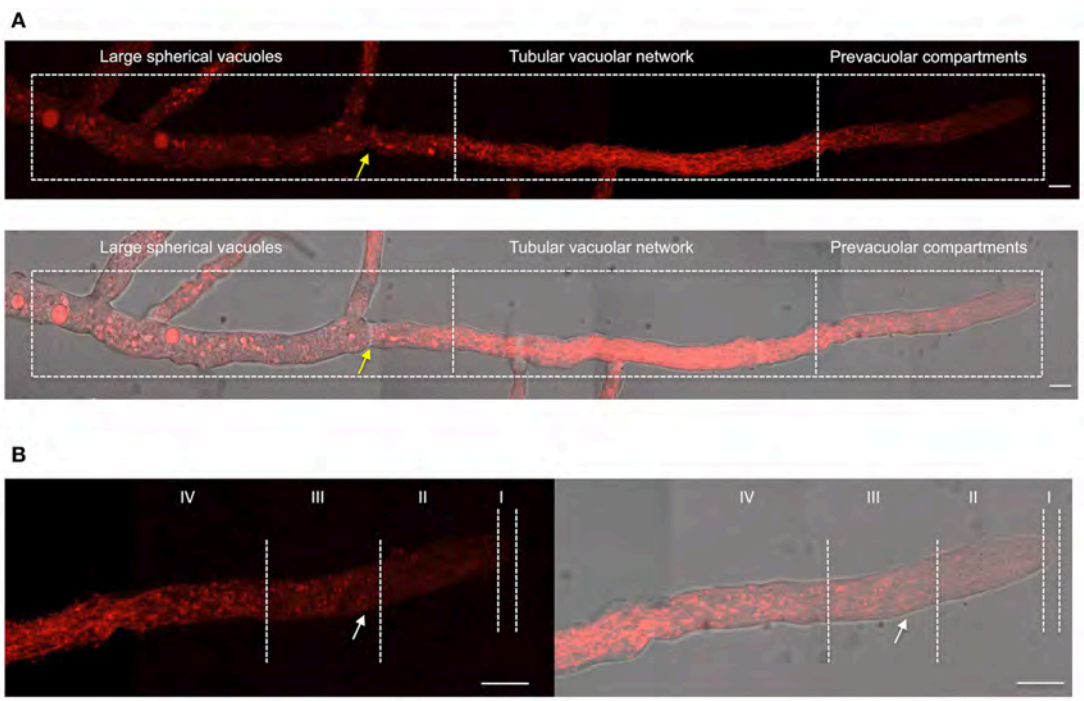

FIGURE 2 | NOX-1 localization during hyphal growth. **(A)** A single hyphae from strain *Δnox-1 nox-1-mCherry e* composed using nine overlapping pictures obtained with fluorescent microscopy (upper panel) and the overlap with the bright field image (lower panel). **(B)** Enlargement of the prevacuolar compartment shown in **(A)** divided in subcompartments I to IV, using the hyphal tip as reference, according to Bowman et al. (2015). Yellow arrows indicate the position of the septum and the white arrow points to one of several u-shaped structures observed. White bars represent 10 μm.

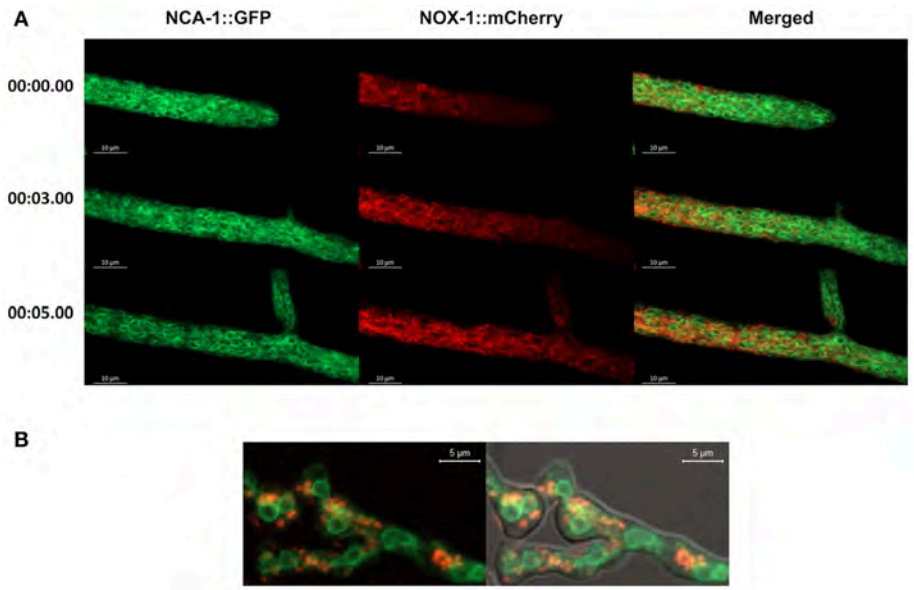

FIGURE 3 | ER-marker NCA-1-GFP shows limited co-localization with NOX-1::mCherry. **(A)** Heterokaryotic hyphae from strains expressing NCA-1::GFP and NOX-1::mCherry were observed by confocal microscopy. Images correspond to time frames from a movie (not shown), as indicated in the left. **(B)** Conidia from NCA-1::GFP and NOX-1::mCherry strains were inoculated under CAT inducing conditions and heterokaryotic germlings observed by confocal microscopy.

observed as ring structures, previously shown to represent the nuclear envelope, distributed along the entire hyphae, including the growing tip. Although NOX-1 is also seen in some ring structures, these are fewer and smaller than NCA-1-labeled nuclear envelopes. Furthermore, double label experiments showed virtually no co-occurrence between NCA-1-GFP and NOX-1-mCherry labeled structures. If any, co-localization was limited to areas with high GFP and mCherry labeling density, while NOX-1 was mostly localized in filamentous structures and largely excluded from the hyphal tip. Likewise, NCA-1 and NOX-1::mCherry showed limited co-localization during CAT induction, where NCA-1 can be observed around putative nuclei and NOX-1 in round structures (**Figure 3B**). This suggested that *N. crassa* NOX-1 is not largely associated to the ER. To confirm this result, we generated strains in which the ER was labeled using a different marker. For this, we transformed wild-type strain 4200 with plasmid pAM01, encoding an ER-lumen targeted GFP (ER-GFP), containing ER-signal and ER-retention sequences from *P. anserina* BiP chaperone protein, a classical ER-marker (Pidoux and Armstrong, 1992; Plemper et al., 1997), fused to *gfp* and expressed from *A. nidulans gpdA* promotor (Meizoso-Huesca A. and Peraza-Reyes L., unpublished). Results in **Figure S3**, show that this protein labeled a reticular network along the entire hyphae, as well as putative nuclear envelope structures, consistent with ER labeling. The difference with NCA-1 ER signal, mostly enriched in putative nuclear envelope structures suggest that NCA-1 and ER-GFP might be enriched in different ER domains. As in the case of NCA-1 (**Figure 3**), NOX-1 presented very limited co-localization with ER-GFP labeled structures in both growing hyphae (**Figure S3A**) and under CAT inducing conditions (**Figure S3B**).

To explore NOX-1 localization in early endosomes, defined as Rab5-labeled organelles, we produced heterokaryons between the NOX-1::mCherry strain and a strain containing the Rab5 GTPase early endosome protein YPT-52 labeled with GFP (Seidel et al., 2013). **Figure 4A** shows that as reported before, in growing hyphae YPT-52 shows a punctate pattern distributed along the entire hyphae, including the tip. Again, it was difficult to appreciate a co-localization of NOX-1 and YPT-52. Furthermore, YPT-52-stained puncta tended to accumulate toward hyphal apical segments in inverse correlation to NOX-1-labeled structures. However, some limited but clear co-localization was observed under CAT inducing conditions. **Figure 4B** and **Video S3** show heterokaryotic conidia formed by cell-cell fusion, one of which shows three initial points of contact between endosomes and NOX-1-labeled organelles (blue arrows). Two of these contact points quickly disappear, while the upper one is maintained for a longer time and finally released. Notably, under these conditions NOX-1 labeled structures were highly pleomorphic, shifting between long filaments (yellow arrows) and dotted structures that were isolated or arranged in circles that assembled and disassembled (white arrows). Moreover, NOX-1 labeled structures seen first as a continuous circular filament a few seconds later become individual round structures, maintaining the circular arrangement (**Video S3**). In summary, these results show that NOX-1 is localized in structures that are consistent with the vacuolar system, and these are very dynamic and pleomorphic, changing their shape during hyphal aging, development, and cell fusion. Moreover, results indicate

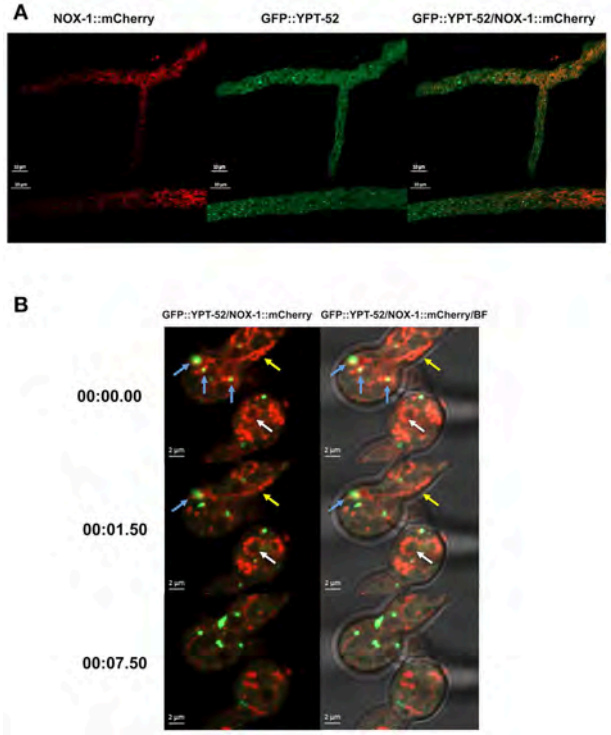

FIGURE 4 | Early endosome marker GFP-YPT-52 shows minor co-localization with NOX-1::mCherry. **(A)** Heterokaryotic hyphae from strains expressing GFP-YPT-52 and NOX-1::mCherry were observed by confocal microscopy. **(B)** Conidia from strains expressing NOX-1::mCherry and GFP-YPT-52 were inoculated under CAT inducing conditions and heterokaryotic germlings were observed by confocal microscopy. Blue arrows indicate co-localization points between GFP-YPT-52 and NOX-1::mCherry, yellow arrows point to NOX-1::mCherry filamentous structures and white arrows point to NOX-1::mCherry structures arranged in a circular shape that change between continuous and dotted patterns (see corresponding **Video S3**).

that NOX-1 shows limited co-localization with early endosomes and the ER.

NOX-1 Co-localizes With Vacuolar ATPase VMA-1

VMA-1 corresponds to subunit "A" of the vacuolar ATPase (V-ATPase). V-ATPases are membrane proteins that hydrolyze ATP to pump protons across the membrane and acidify the lumen of vacuoles and other cell compartments. In *N. crassa*, VMA-1 has been localized in the entire vacuolar system (Bowman et al., 2015), displaying a pattern very similar to the one we report here for NOX-1. To determine if these two proteins co-localize, a *Δ*nox-1 NOX-1-mCherry/VMA-1-GFP heterokaryon was analyzed by confocal microscopy. As reported, we detected VMA-1 in ring and tubular structures that correspond to the vacuolar system. Notably, VMA-1 and NOX-1 co-localized in the same structures **(Figure 5)**, except in the region of large spherical vacuoles in which NOX-1 was localized in the luminal part of the vacuoles and VMA-1 in the periphery.

To further confirm NOX-1 localization in the vacuolar system, we stained the *Δnox-1 NOX-1::mCherry* strain with carboxy-DFFDA, a molecule that accumulates in fungal acidic vacuolar compartments, producing a fluorescencent signal (Richards et al., 2012; Bowman et al., 2015; Rico-Ramirez et al., 2018). As shown in **Figure 6A**, NOX-1::mCherry localized in the same compartments stained by carboxy-DFFDA, including the luminal region of the large spherical vacuoles. The same co-localization was observed during conidia germination and CAT fusion, and as before, the shape of the vacuolar system was composed of larger and less filamentous structures (**Figure 6B**).

NOX-1 Is Also Partially Localized at the Plasma Membrane

In plants, NOX AtrbohC has been detected at the plasma membrane of root hair cells, where it plays a critical role in polar growth (Takeda et al., 2008). We addressed the possibility that in our experiments NOX-1 membrane localization was being overshadowed by the strong NOX-1::mCherry organellar signal, derived from its constitutive expression. First, we used latrunculin A to inhibit the endocytic process, as a strategy to increase possible NOX-1 plasma membrane signal. As expected, latrunculin A delayed hyphal tip growth and under these conditions some NOX-1::mCherry signal was detected at the plasma membrane (not shown).

To further confirm our NOX-1 localization results, we generated strains in which *nox-1::mCherry* was expressed from its native promoter. As shown in **Figures S4A–E**, expression of NOX-1::mCherry from *nox-1* promoter also resulted in full complementation of all *Δnox-1* defects. When strain *Pnox-1-nox-1::mCherry* was analyzed by confocal microscopy, it was evident that the fluorescence signal produced from the *nox-1* promoter was lower than the one produced from *ccg-1* promoter. Nevertheless, it could be appreciated that NOX-1::mCherry was largely absent from hyphal tips and formed a tubular network behind the tip, showing a vacuolar system pattern very similar to the one observed before (not shown). After increasing laser intensity, it was possible to confirm that NOX-1::mCherry signal also localized to the entire vacuolar system (**Figure 7A**), showing a pattern virtually identical to the one observed using the *ccg-1* promoter (**Figure 2**). Notably, under these conditions NOX-1 also was detected at the cell surface, consistent with plasma membrane localization. This was reproducibly observed in hyphal regions corresponding to the tubular vacuolar network and large spherical vacuole regions (**Figures 7A,B**). However, NOX-1 plasma membrane localization at the prevacuolar compartment region and hyphal tip was not as consistent, and only in some cases NOX-1 localized to the cell surface at the hyphal tip (**Figure S3A**, white arrows). After confirming that NOX-1::mCherry localization is alike whether expressed from *ccg-1* or *nox-1* promoters, we continued our NOX-1 localization studies using strains that expressed NOX-1::mCherry from *ccg-1* promoter, as their stronger signal allowed longer imaging acquisition and lower photo-bleaching.

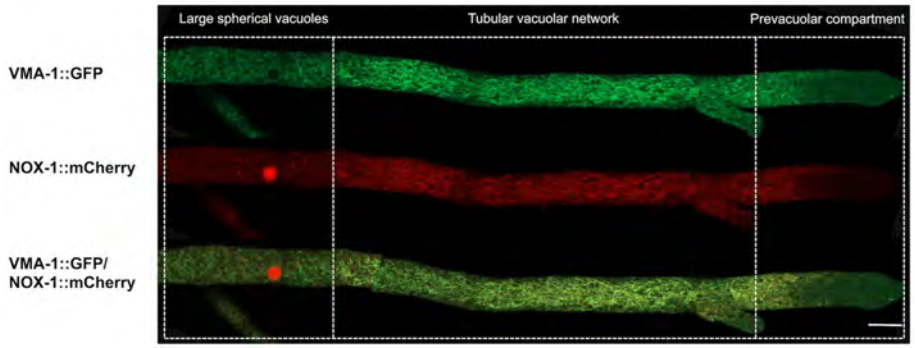

FIGURE 5 | NOX-1::mCherry co-localizes with the vacuolar system marker VMA-1 ATPase. **(A)** Heterokaryotic hyphae from strains expressing NOX-1::mCherry and VMA-1::GFP were observed by confocal microscopy. Bar corresponds to 20 μm.

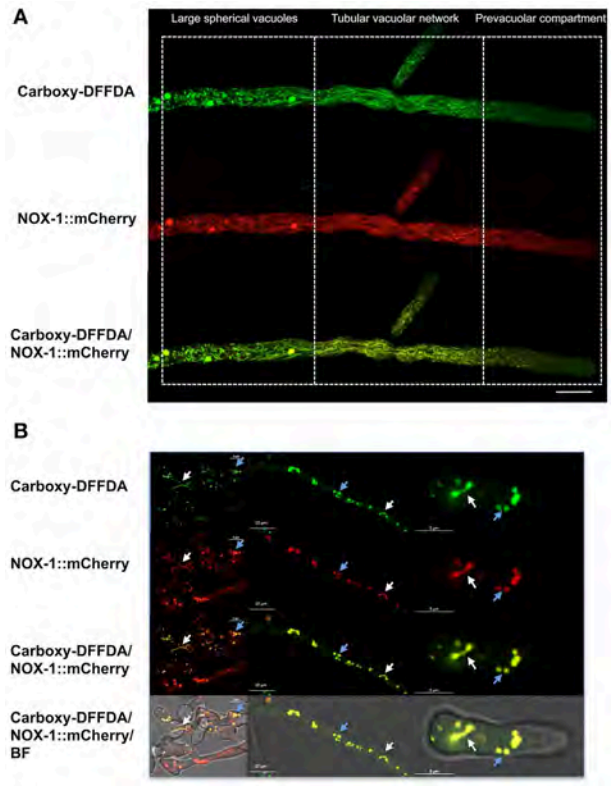

FIGURE 6 | NOX-1::mCherry co-localizes with the vacuolar system marker carboxy-DFFDA. **(A)** Hyphae from strains expressing NOX-1::mCherry were stained with carboxy-DFFDA and observed by confocal microscopy. **(B)** Conidia from strain NOX-1::mCherry were induced to form CATs (left panels) or to germinate (middle and right panels), stained with carboxy-DFFDA, and observed by confocal microscopy.

NOX-1 and Regulatory Subunit NOR-1 Co-localize Only at Very Discrete Compartments

While NOX-1 contains 6 putative transmembrane domains, its regulatory subunit NOR-1 lacks any clear signal peptide or transmembrane domain. However, since NOR-1 is required for NOX-1 function, we decide to compare the localization of both proteins. For this purpose, we generated a PCR construct coding for NOR-1 fused to GFP at the C-terminus and used it to transform strain FGSC-9718. Three homokaryotic strains were obtained in which the *nor-1::GFP* construct replaced the *nor-1* gene, as confirmed by Southern blot analysis (not shown). These strains showed a wild type phenotype, indicating that GFP tagging of NOR-1 did not affect its activity. However, when these strains were observed by confocal microscopy GFP signal was very low and difficult to detect (not shown). Therefore, we expressed *nor-1::GFP* from the *ccg-1* promoter as we did for NOX-1::mCherry. For this, we generated plasmid pNCNOR-1::GFP18 and used it to transform *Δnor-1* mutant strain Nc28nor-1. Ten transformants were obtained, from which GFP fluorescence positive strains were screened using epifluorescence microscopy. Two of these were confirmed by PCR (**Figure S5**) and used for NOR-1 localization experiments. This *nor-1::gfp* allele was able to restore all asexual, sexual and growth defects of *Δnor-1* mutants, indicating its full functionality (**Figure S6**).

NOR-1::GFP fluorescence pattern was very different form the one observed for NOX-1. In growing hyphae, it was detected as a fine granular pattern along the entire hyphae and also in a few larger puncta. NOR-1 was clearly present in the hyphal tip, very likely at the plasma membrane and mainly confined to the apical dome (**Figure 8A** and **Figure S7A**). Notably, NOR-1 did not show any clear co-localization with NOX-1 in growing hyphae **(Figure 8A)** or germinating conidia (**Figure S8B**), where NOR-1::GFP was observed in punctate structures close to the plasma membrane (**Figure S7C**). In older hyphal regions (**Figure S7B**) and in intact conidia (**Figure S8A**), NOR-1::GFP displayed a punctuate pattern. In conidiophores (**Figure S8A**) both NOR-1 and NOX-1 showed the circular dotted structures described before for NOX-1 under CAT inducing conditions (**Figure 4B**). In some cases, NOR-1 and NOX-1 dotted structures seemed to be intercalated and in few cases the two signals co-localized, suggesting that NOR-1 and NOX-1 localize to specific domains of these structures, where they can eventually converge. Because both NOX-1 and NOR-1 are essential for CAT fusion, we incubated conidia from NOX-1::mCherry and NOR-1::GFP

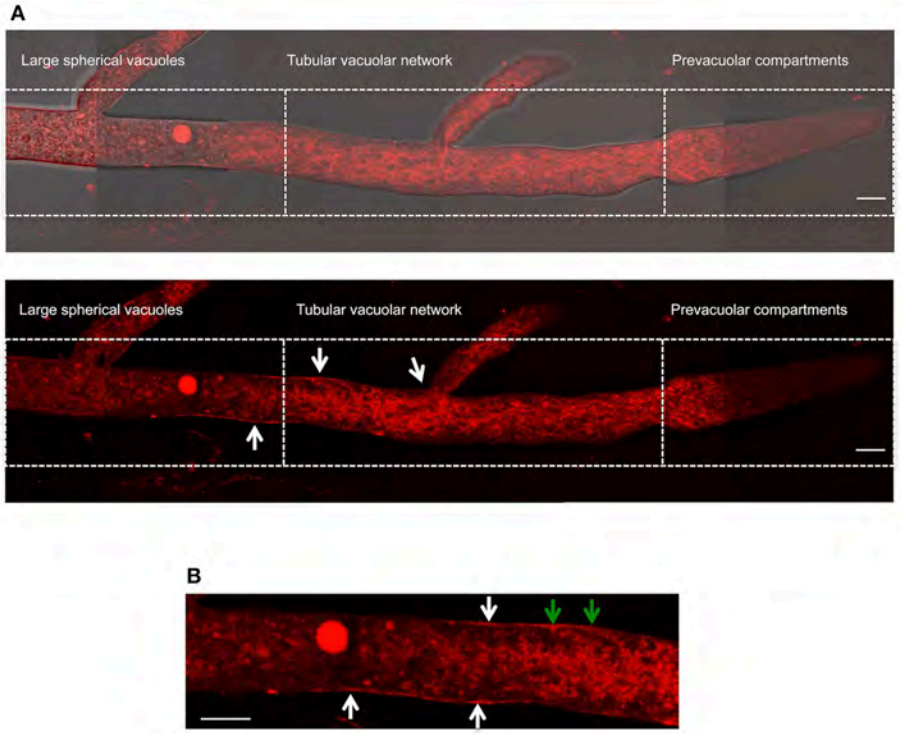

FIGURE 7 | Localization of NOX-1::mCherry expressed from native *nox-1* promoter during hyphal growth. **(A)** Composition of a hypha using overlapping pictures obtained with fluorescent microscopy (lower panel) merged with the corresponding bright field image (upper panel), and divided in compartments as in **Figure 2**. The bars indicate 10 μm. **(B)** Enlargement of a region around the intersection between large spherical vacuoles and tubular vacuolar network compartments shown in **(A)** (lower panel). strains at high density and made observations after 4 h, where profuse CAT fusions take place. Under these conditions, we observed both clear segregation and co-localization of NOR-1 and NOX-1 signals. **Figure 8B** shows three heterokaryotic conidia (i.e., after cell fusion) at different germination stages. The two top conidia show a NOX-1 pattern, consisting of strands and puncta located within cells and at the cell surface. In addition, NOX-1 also decorated the periphery of what appears to be large vacuolar structures. In these conidia NOR-1::GFP displays a different pattern, with isolated puncta located at the cell surface and a septum. In the conidium at the bottom of the figure, which is in a more advanced stage of germination and has fused with a contiguous conidium, NOX-1 localization pattern is similar to the one described above. However, NOR1-GFP more conspicuously stained the hyphal tip at this stage (white arrow), and clear co-localization of NOR-1 and NOX-1 was observed in puncta located at the cell surface, the cytoplasm and the cell-cell fusion interface, as well as some associated with putative large vacuoles (yellow arrows). Together, these results suggest a dynamic localization of NOR-1 and NOX-1 at specific domains of the plasma membrane and the cytoplasm–notably including the vacuolar system–, where they interact at specific compartments, which are enriched during the cell-fusion interactions that occur under CAT inducing conditions.

NOX-1 Single Amino Acid Substitutions in NADPH-Binding Sites Result in a Complete Lack of Function

We took advantage of the functionality of NOX::mCherry to evaluate the effects of specific amino acid substitutions in NOX-1 function. The analysis of mutations in human CYBB gene, encoding gp91phox catalytic subunit, or NOX2, showed that the substitution of proline 415 by histidine resulted in a lack of oxidase enzyme activity but preservation of the inactive protein. The same was observed with mutations replacing arginine 537 by cysteine (Rae et al., 1998). These amino acids, which are part of the NADPH-binding sites, are highly conserved in the NOX from filamentous fungi (**Figure S9**), and correspond to NOX-1 proline 382 and cysteine 524. We used plasmid pNCNOX-1::mCherry4 to introduce point mutations by PCR in the corresponding codons, to generate NOX-1-mCherry proteins with P382H and C524R substitutions. The resulting plasmids were confirmed by DNA sequencing and used to transform *Δnox-1 his-3* strain. Two transformants confirmed by PCR were named *NOX-1P382H-mCherry Δnox-1* and *NOX-1C524R-mCherry Δnox-1* and used for further experiments. The analysis of the corresponding strains by confocal microscopy showed that the signal intensity and localization of the mutant proteins was very similar to wild type NOX-1 (**Figure S10**). Nevertheless, *nox-1*^{P382H}*-mCherry*

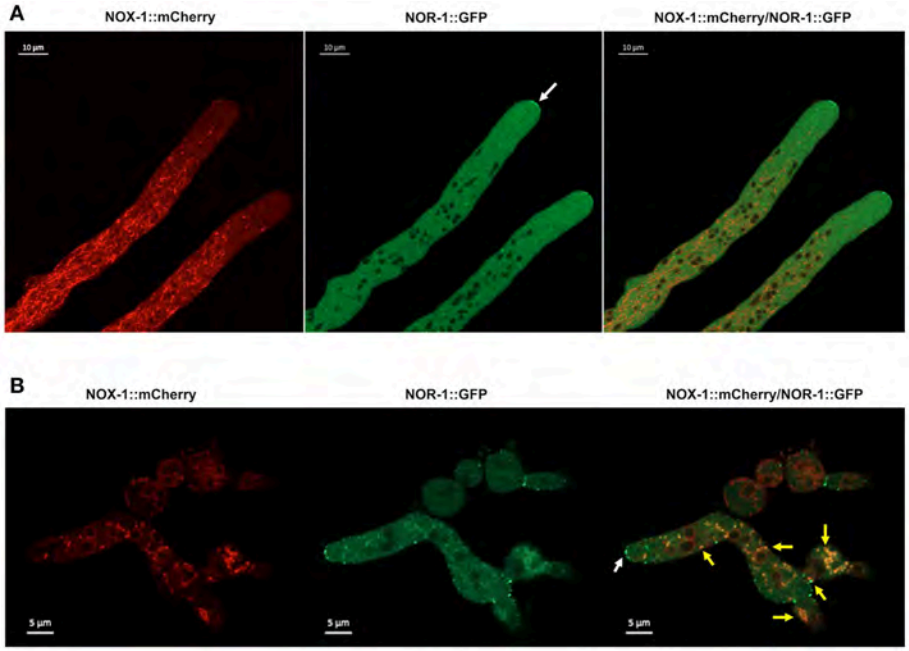

FIGURE 8 | NOX-1::mCherry co-localizes with NOR-1::GFP during CAT inducing conditions. **(A)** Heterokaryotic hyphae from strains expressing NOX-1::mCherry and NOR-1::GFP were observed by confocal microscopy. A white arrow points to NOR-1::GFP enrichment at the hyphal tip. **(B)** Conidia from NOX-1::mCherry and NOR-1::GFP strains were incubated under CAT inducing conditions and observed by confocal microscopy. The white arrow indicates NOR-1::GFP localized at the hyphal tip in a dotted pattern and yellow arrows indicate single dot or dotted regions where NOX-1 and NOR-1 co-localize.

and *nox-1*^{C524R}*-mCherry* alleles were unable to complement any of the defects observed in *Δnox-1* mutants (**Figures S11A–F**). These results indicate that all NOX functions depend on its oxidase activity.

DISCUSSION

NOX-1 Is Localized in the Vacuolar System

The localization of a protein is a determinant of its functions. Previous reports on NOX subcellular localization in different filamentous fungi concluded that these enzymes are mainly associated to the ER. In *P. anserina*, PaNox1-GFP tagging resulted in a reticulate pattern, in some cases perinuclear, showing high co-localization with an ER marker in young hyphae, while in older hyphae a cortical punctuated pattern was more frequent. The authors concluded that PaNox1 is mainly localized in the ER, as well as in cortical vesicles originated from the ER and presumably involved in the vacuolar network (Lacaze et al., 2015). However, the ER marker consisted of mCherry tagged with the predicted secretion signal from NOX subunit PaNoxD and the KDEL ER-retention signal, and no other independent ER marker was used.

In *B. cinerea*, BcNoxA and BcNoxB GFP fusions expressed constitutively were localized in similar structures in germinated conidia. Both GFP-NoxA and NoxB-GFP showed partial co-localization with an ER-tracker signal, in some cases in structures surrounding nuclei (Siegmund et al., 2013). In *Claviceps purpurea*, mCherry fusions of CpNox1 and CpNox2, not tested for functionality, were expressed constitutively and localized using epifluorescence microscopy. Using ER-Tracker Blue-White DPX, these authors concluded that CpNox1 and CpNox2 appeared to be located mainly in the ER while CpNox2 also showed a tendency to accumulate in unspecified vacuoles (Schurmann et al., 2013). In support of ER localization, Siegmund et al. (2015) showed that a *B. cinerea* GFP::BcNoxA fusion designed to be artificially retained in the ER, by addition of the HDEL motif, restored the pathogenicity defects of a *ΔbcnoxA* mutant. However, the fact that this fusion failed to complement *ΔbcnoxA* CAT fusion and sclerotia formation defects, led the authors to propose that BcNoxA has functions both inside and outside the ER (Siegmund et al., 2015). However, the possibility that GFP::BcNoxA::HDEL could leak from the ER cannot be excluded, as it is known that some KDEL bearing proteins are localized outside the ER (Soares Moretti and Martins Laurindo, 2017). In search of possible NOX functions at the ER, Marschall and Tudzynski (2017) detected physical interaction between BcNoxA and putative ER disulfide isomerase protein BcPdi1, and showed that *ΔbcnoxA* and *Δbcpdi1* mutants display similar phenotypes (Marschall and Tudzynski, 2017). However, there is increasing evidence indicating that disulfide isomerases can be located and have functions outside the ER (Soares Moretti and Martins Laurindo, 2017).

Our results using confocal microscopy show that functional versions of *N. crassa* NOX-1, expressed either from a constitutive promoter or from its own promoter, display limited co-localization with the ER and early endosomes and

are mainly associated to the entire vacuolar system, as defined by the organellar system labeled by the vacuolar ATPase VMA-1 and the fluorescent molecule carboxy-DFFDA. The fact that in older hyphal regions the NOX-1::mCherry signal is located in the lumen of large vesicles suggests that NOX-1 degradation might occur in these cell compartments, as it has been observed for other vacuolar membrane proteins such as NCA-2, NCA-3, and CAX but not for VMA-1, which does not contain transmembrane domains (Bowman et al., 2009). In addition, NOX-1 proteolysis could result in cleavage of the mCherry tag. Although the reasons for these differences in fungal NOX localization (mainly ER *vs.* mainly vacuolar) are not known, they might be related to (i) the biological dissimilarity between *N. crassa* and the other fungi studied; (ii) the fact that different cell types or regions were studied in different fungi or (iii) technical and methodological reasons.

As shown before (Bowman et al., 2015; Rico-Ramirez et al., 2018) and in this work, *N. crassa* vacuolar system is a highly dynamic and pleomorphic structure, showing dramatic changes in shape during growth, aging, and development. In growing hyphae, the tubular vacuolar region has also been named as network of elongated cisternae or NEC. Studying the co-expression of CSE-7, a chaperone required for ER exit of some proteins, and different ER markers, Rico-Ramirez et al. (2018) concluded that what has been defined as ER and NEC show some overlap. How extensive this overlap is, structurally as well as functionally, is yet to be defined. However, it should be noted that while the subcellular localization of proteins depends mainly on their targeting signals, the accumulation of DFFDA and its fluorescence depends on specific transporters and an acidic pH, both associated with vacuolar compartments and not with the ER. Indeed, DFFDA never stains the nuclear envelope or the hyphal tip regions, while ER markers are readily detected in these regions. As NOX-1, VMA-1, and DFFDA largely stain the same compartments, we conclude that such compartments correspond to the vacuolar network. Interestingly, NOX2 and V-ATPase not only are both located in mammalian phagosomes, but V-ATPase activity is required for NOX2 oxidase activity (Rybicka et al., 2012).

Fungal vacuoles have functions similar to animal lysosomes and plant vacuoles (Richards et al., 2012). They play essential roles in protein and organelle degradation, xenobiotic detoxification, cellular pH, and osmotic homeostasis, and the storage of metabolites and critical ions like iron and calcium. We propose that some of these processes are ROS-regulated by NOX enzymes capable to produce low levels of ROS in the vacuolar lumen (see below), as exemplified by the redox regulation of cysteine cathepsin proteases in phagosomes (Rybicka et al., 2012).

NOX-1 Is Also Localized at the Plasma Membrane

Although in growing hyphae most of the NOX-1-mCherry fluorescence signal was associated to the vacuolar system, we also detected part of NOX-1 at the plasma membrane, particularly in areas that correspond to the tubular vacuolar network and large spherical vacuoles regions. Polarized growth in plants has been associated with plasma membrane enrichment of specific NOX enzymes at the tip of root hair cells (Takeda et al., 2008). As *Δnox-1* mutants are affected in radial growth and growth of aerial mycelium, this suggests that NOX-1 plasma membrane localization might be linked to polar growth in this fungus. However, NOX-1 localization at the plasma membrane of the hyphal tip was observed only in some instances, including when latrunculin was used to partially inhibit endocytosis, and even in these cases the enzyme was not particularly enriched at the tip. This might be related to the fact that this region moves out of focus during growth, or it could indicate that NOX-1 membrane localization at the hyphal tip is transient and highly dynamic. In contrast, the NOX-1 regulatory subunit NOR-1 was indeed enriched at the hyphal tip (see below). In *M. oryzae*, using a NOX1-GFP fusion expressed from its own promoter and epifluorescence microscopy, Egan et al. (2007) detected faint GFP fluorescence at the periphery of appressoria, suggesting that NOX1 was localized at the plasma membrane. Notably, this fusion was also partially localized in the appressorium central vacuole, but its localization was not studied in other conditions. Although in *B. cinerea*, NoxA and NoxB were associated to the ER, faint fluorescence was also detected at the plasma membrane (Siegmund et al., 2013). It is not uncommon that only a portion of the total amount of cellular NOX is localized at the plasma membrane. In resting dendritic cells, only about 10% of total NOX2 is present on the plasma membrane and this increases to about 22% after zymosan stimulation, while a significant amount of this enzyme is detected in late endosomes and lysosomes (Dingjan et al., 2017).

NOX-1 and NOR-1 Co-localize Only in Some Specific Compartments

As *Δnor-1* mutant phenotypes recapitulate the phenotypes of both *Δnox-1* and *Δnox-2* mutants, it has been considered that NOR-1 is necessary for the activity of both enzymes. Therefore, it was unexpected to find that NOX-1 and NOR-1 co-localize in only some cell compartments. Our NOR-1 localization results are largely consistent with the localization of NOR-1 orthologs in other fungi. In the plant symbiont *Epichloë festucae* grown in axenic culture, a NoxR-GFP fusion, not tested for functionality and expressed from a constitutive promoter, was detected in septa and hyphal tips showing both punctuated and more homogeneous patterns behind the tip. The hyphal tip localization depended on the presence of NoxR PB1 domain (Takemoto et al., 2011). In *B. cinerea*, a constitutively expressed functional GFP-BcNoxR fusion was detected in granules irregularly distributed throughout the vegetative hyphae. In some cases these granules were moving toward the hyphal tip, and no co-localization with BcNoxA or BcNoxB was observed (Siegmund et al., 2013). In *C. purpurea* a CpNoxR::mCherry fusion, not tested for functionality and expressed constitutively was detected equally distributed in the cytoplasm as well as within mobile particles (Schurmann et al., 2013). In *P. anserina*, PaNoxR was detected in a diffuse cytoplasmic pattern in young hyphal regions and in a punctuated pattern in older regions. In some cases PaNoxR was detected at

the tip of growing hyphae, as well as the tip of hyphae undergoing anastomosis, and PaNox1 and PaNoxR co-localization was only observed in vesicles and never at ER-type structures or the hyphal tip (Lacaze et al., 2015).

We found that NOX-1 and NOR-1 co-localization is mainly observed in vesicular structures formed during CAT formation and cell-cell fusion conditions. It is possible that all the defects observed in *Δnor-1* and *Δnox-1* mutants could be explained by their inability to undergo cell fusion, both during hyphal growth and CAT fusion. Indeed, many mutants screened as defective for cell fusion were also affected in radial growth, aerial mycelium growth and were female sterile during sexual differentiation (Fu et al., 2011). CAT development is a complex process and more than 70 genes involved in cell recognition, chemotropic interactions and cell fusion have been identified in filamentous fungi. Among these NOX-1 and NOR-1 are essential for cell fusion in different fungi [see (Fischer and Glass, 2019) for a comprehensive review]. Interestingly, we have found that *Δnox-1* conidia cannot fuse with wild type conidia, indicating that a functional NOX-1 is needed in the fusing cells and highlighting the importance of NOX-1 during this process.

NOX-1 Oxidase Activity Is Essential to Regulate Growth and Development in *N. crassa*

We have demonstrated that the substitution of a single amino acid in two different NADPH-binding sites is enough to render NOX-1 inactive. This indicates that the oxidase activity of NOX-1 is essential for its functions, as opposed to NOX-1 possible roles as a scaffolding protein, capable to interact with several proteins. NOX transport of the electrons taken form NADPH across a membrane not only produces superoxide and derived ROS, but can also affect the pH on either side of the membrane. This, in turn, affects electrochemical-driven ion fluxes and cell turgor (Segal, 2016). Because these two functions cannot be separated, the critical question on which NOX functions are attributed to the production of ROS and which to the associated changes in pH remains unanswered and therefore, it cannot be ignored that NOX enzyme function has these two effects.

The fact that electron transport activity can be induced *in vitro* by adding NADPH to purified and relipidated NOX2 (Koshkin and Pick, 1993) indicates that there is a low basal activity that seems independent of its regulatory subunits. Therefore, it is possible that the NOX-1 we observe in the vacuolar network could have some NOR-1 independent activity in this cell compartment, which might be important to regulate the acidic pH and contents of the vacuolar system, as well as cell turgor.

In addition, some NOX-1 targeted to the plasma membrane might be endocyted and fused with NOR-1 containing vesicles to generate a fully active enzyme and produce high ROS levels inside these vesicles. Some of these vesicles could travel back to the plasma membrane and release ROS to the extracellular space, where they could participate in cell-wall remodeling, defense and cell-cell communication (Aguirre and Lambeth, 2010). Some of these vesicles containing fully active NOX-1 could also be directed to specific cell compartments, where they could fuse and release ROS, as a way of generating different oxidation conditions in time and space.

In dendritic cells, where a sustained production of ROS is needed in the phagosome, it has been recently shown that lysosomes contain a large portion of inactive NOX2, which is recruited to the phagosome to replenish inactive oxidized NOX2 (Dingjan et al., 2017). Therefore, it is possible that part of the NOX-1 present in the fungal vacuolar system could also be a NOX-1 reservoir to be directed to NOR-1-containing or other cell compartments.

DATA AVAILABILITY

The raw data supporting the conclusions of this manuscript will be made available by the authors, without undue reservation, to any qualified researcher.

AUTHOR CONTRIBUTIONS

JA designed experiments, wrote the manuscript, and obtained funding. NC-D performed and designed experiments, and contributed to manuscript writing. BB and LP-R contributed materials, and to discussion and manuscript writing.

FUNDING

This work was supported by CONACYT grants Investigación en Fronteras de la Ciencia 2015-I-319, CONACYT-DFG 277869 and PAPIIT-UNAM IN200719 and IV200519.

ACKNOWLEDGMENTS

We are deeply grateful to Meritxell Riquelme (CICESE), for providing the endosome labeled strain, Oregon Green, and helpful discussions and Olivia Sánchez and Mariana Angélica Robledo (supported by a postdoctoral fellowship form DGAPA-UNAM) for technical assistance. We also thank Dr. Fernando García and Dr. Abraham Rosas-Arellano from IFC Imagenology unit for help with confocal microscopy, as well as to IFC-UNAM Molecular Biology and Computer Units.

Chromaffin Cells of the Adrenal Medulla: Physiology, Pharmacology, and Disease

Emilio Carbone,[1] *Ricardo Borges,*[2] *Lee E. Eiden,*[3] *Antonio G. García,*[4] *and Arturo Hernández-Cruz*[*5]

ABSTRACT

Chromaffin cells (CCs) of the adrenal gland and the sympathetic nervous system produce the catecholamines (epinephrine and norepinephrine; EPI and NE) needed to coordinate the bodily "fight-or-flight" response to fear, stress, exercise, or conflict. EPI and NE release from CCs is regulated both neurogenically by splanchnic nerve fibers and nonneurogenically by hormones (histamine, corticosteroids, angiotensin, and others) and paracrine messengers [EPI, NE, adenosine triphosphate, opioids, γ-aminobutyric acid (GABA), etc.]. The "stimulus-secretion" coupling of CCs is a Ca^{2+}-dependent process regulated by Ca^{2+} entry through voltage-gated Ca^{2+} channels, Ca^{2+} pumps, and exchangers and intracellular organelles (RE and mitochondria) and diffusible buffers that provide both Ca^{2+}-homeostasis and Ca^{2+}-signaling that ultimately trigger exocytosis. CCs also express Na^+ and K^+ channels and ionotropic (nAChR and $GABA_A$) and metabotropic receptors (mACh, PACAP, β-AR, 5-HT, histamine, angiotensin, and others) that make CCs excitable and responsive to autocrine and paracrine stimuli. To maintain high rates of E/NE secretion during stressful conditions, CCs possess a large number of secretory chromaffin granules (CGs) and members of the soluble NSF-attachment receptor complex protein family that allow docking, fusion, and exocytosis of CGs at the cell membrane, and their recycling. This article attempts to provide an updated account of well-established features of the molecular processes regulating CC function, and a survey of the as-yet-unsolved but important questions relating to CC function and dysfunction that have been the subject of intense research over the past 15 years. Examples of CCs as a model system to understand the molecular mechanisms associated with neurodegenerative diseases are also provided. Published 2019. *Compr Physiol* 9:1443-1502, 2019.

Didactic Synopsis

Major teaching points

1. During stress, chromaffin cells (CCs) from the adrenal medulla release a surge of catecholamines (CAs) [epinephrine (EPI) and norepinephrine (NE)] into the bloodstream, which serves to prepare the different organs of the body for the fight-or-flight response, to escape from danger and survive.

2. Classically, the secretory response of CCs is triggered by a rapid elevation of the Ca^{2+} concentration in the cytosol, mainly contributed by Ca^{2+} entry via voltage-activated Ca^{2+} channels that open upon membrane depolarization as a consequence of the activation of postsynaptic cholinergic receptors by the neurotransmitter acetylcholine (ACh) that is released from splanchnic nerve terminals. Pituitary adenylate cyclase-activating polypeptide (PACAP) co-released with ACh at the adrenomedullary synapse contributes to CA secretion from the adrenal medulla during stress.

3. CCs express many types of Na^+, Ca^{2+}, and K^+ channels that are also able to generate spontaneous "neuronal-like" tonic and burst-firing patterns that can drive a sustained "nonneurogenic" release of CAs upon stimulation by various secretagogues.

4. The Ca^{2+} signal due to Ca^{2+} entry is subsequently modulated by Ca^{2+} uptake and release in mitochondria and endoplasmic reticulum (ER). Intracellular Ca^{2+} controls

This article is a U.S. Government work and is in the public domain in the U.S.A.

granule movement to the plasma membrane, exocytosis and endocytosis, and couples cell activity to adenosine triphosphate (ATP) generation.

5. CAs, chromogranins, ATP, GABA, opioids, and other peptides are tightly packaged in secretory granules (SGs) that release their contents by fusion with the plasmalemma. In this process (exocytosis) several soluble NSF-attachment receptor complex (SNARE) proteins participate in regulating the formation of a membrane fusion pore and its subsequent expansion to release the granule content.

6. CAs are preferentially released from newly synthetized granules. Older granules may act as CA donors for newly formed granule reloading.

7. Secretagogues of the adrenal medulla stimulate both CA/peptide synthesis and release via "stimulus-secretion-synthesis coupling." CC excitability, Ca^{2+} channel currents and the ensuing secretory responses are regulated further by several receptors for opioids, PACAP, ATP, GABA, and various other neurotransmitters.

8. Altered cell excitability, Ca^{2+}-handling, and exocytosis defects have been reported in CCs from rodent models of diseases such as hypertension, Alzheimer's disease, Huntington's disease (HD), autism, and amyotrophic lateral sclerosis, suggesting that the defective proteins of the disease also have an impact on CC function.

Introduction

The adrenal glands are endocrine organs that reside above the kidneys in mammals and, as such, have also been called "suprarenal" glands. The inner part of the adrenal is the medulla, a tissue originating from the neural crest, and surrounded by the cortex. Both cortex and medulla contribute critically to the body's responses to stress. At the beginning of the 19th century, Alfred Kohn coined the term "chromaffin" for adrenal medulla catecholamine-containing cells, which can be stained by a chemical reaction to chromium (113). Since then, CCs have provided one of the most successful models for the study of nerve cells, especially for the stimulus-secretion coupling process and its regulation (394).

During intense fear, metabolic stress, exercise, or struggle, adrenal CCs release into the blood stream EPI and NE necessary for regulating the "fight-or-flight" response (96). These potent chemical messengers bind to their molecular targets, the adrenergic receptors, distributed throughout the entire organism, and prepare it for maximal muscle performance and motor responsiveness by increasing heart pumping strength and blood pressure, producing vasodilation in the blood supply of skeletal muscles and heart, and vasoconstriction in the skin and gastrointestinal vasculature. At the same time, mobilization of glucose from the liver is enhanced, while bronchioles dilate to optimize blood oxygenation and pupils dilate to improve visual acuity. Released CAs also promote relaxation of smooth muscle in tissues not required for a stress response such as the intestinal tract or the uterus (570).

The adrenal medulla performs these tasks, by virtue of its unique functional organization: Preganglionic sympathetic nerve fibers originating from cell bodies in the thoracolumbar segments of the spinal cord bypass the celiac ganglion without making synapses and form the splanchnic nerve, which innervates CCs directly. These synaptic terminals release ACh, that upon binding to postsynaptic nicotinic receptors in CCs, induces a rapid membrane depolarization. This triggers action potentials (APs) that allow Ca^{2+} influx, followed by rapid elevation of the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$). Ca^{2+} elevation then triggers the fusion of SGs with the plasma membrane and the exocytotic release of CAs. The neurogenic control of CCs permits a continuum of CA output, from a firing rate of splanchnic nerve impulses of about 1 Hz, sufficient to maintain resting cardiovascular, respiratory, and metabolic functions (247, 249, 506), to nerve fiber discharges at maximum rates equal or higher than 10 Hz producing a massive release of CAs during stress (569).

The first synapse described electron microscopically was the splanchnicoadrenomedullary synapse (139). Earlier, the storage of CAs within SGs of adrenal medulla was characterized (299). The concept of exocytosis was developed from the observation of the secretion of a highly charged, >70 kDa protein, chromogranin A (CgA), unlikely to be released by diffusion across cell membranes, from the adrenal medulla following splanchnic nerve stimulation (280, 673). Ca^{2+}-dependence of exocytosis was also demonstrated in the adrenal medulla (176), culminating in Douglas's concept of stimulus-secretion coupling (172), analogous to the muscle stimulus-contraction coupling.

CCs resemble neurons in many ways. Besides their synaptic input, they receive chemical signals both from their neighbors (paracrine signal) and from themselves (autocrine signal). Some of them are electrically coupled (261). Their excitable properties originate from a surprisingly wide variety of ion channels, comparable to those of many central neurons (389, 394). Thus, far from being passive followers of their neurogenic input, these cells can decode and integrate different types of extra- and intracellular signals to generate complex patterns of electrical and cytoplasmic second messenger signaling that culminate in the regulated release by exocytosis of potent chemical messengers, which include CAs, opioids and other peptides, ATP, and GABA.

The unique properties of CCs derive from their embryological origin: they belong to both the nervous and the endocrine systems (16, 628). Their neuron-like phenotype has been particularly valuable over more than 30 years of research to understand excitability, nerve impulse generation, synaptic transmission, regulated neurotransmitter secretion, and the actions of drugs that regulate central nervous system (CNS)

function (70). CCs have also been crucial for understanding the basic mechanisms of intracellular Ca^{2+} dynamics and neurochemical transmission through secretory vesicles or CGs. The CGs were first isolated from the bovine adrenal medulla and their releasable cargo analyzed (215). Most of the vesicular proteins involved in the secretory machinery were first definitively characterized in CCs (86, 163, 301, 583, 601). CCs, together with the pheochromocytoma cell line (PC12) isolated from a rat tumor of adrenomedullary origin in 1976 (257), have been the major cell types employed in the development and refinement of patch-clamp and amperometric recording techniques. These two independent but complementary electrophysiological approaches have been indispensable in clarifying most of the now-known molecular mechanisms that regulate cell excitability, Ca^{2+}-dependent secretion, and the molecular apparatus that regulates vesicle fusion (394, 667).

Starting with the seminal work of Levi-Montalcini and Unsicker (16, 628), showing that CCs can transdifferentiate into sympathetic neurons when exposed to nerve growth factor (320, 325), adrenal CCs have extended our understanding of neural development. Much of our present knowledge of the physiology and pathophysiology of neuropeptide and monoamine neurotransmitters stems from studies in CCs. More recently, CCs have been valuable in studies of neurodegenerative processes, tumorigenesis, and drug development (157, 435). This article aims at providing the reader with a broad view of both classical and recent advances concerning the molecular mechanisms regulating the secretory function of these remarkable cells, as well as their concerted role within the adrenal medulla as an endocrine organ responsible for integrating physiological responses to a range of homeostatic challenges.

The sympathoadrenal medulla connection

It is recognized that in higher organisms the brain regulates the "milieu interieur" (60) and body homeostasis (95). This regulation ensures that under normal conditions, blood glucose, oxygen, electrolyte concentrations, body temperature, blood pressure, heart rate, respiration, and blood flow to vital organs do not vary much or for very long. To maintain the integrity of the organism, the brain controls the inner world via feedback-regulated systems. Cannon introduced three concepts focused on the adrenal medulla that are well known and widely accepted: homeostasis, the "fight-or-flight" response, and the functionally unitary nature of the sympathoadrenal system. The autonomic nervous system has two divisions, parasympathetic and sympathetic. The sympathetic nervous system (SNS) comprises a large variety of cells. Thus, sympathetic neurons form the pre- and paravertebral ganglia and their axonal noradrenergic nerve terminals innervate and regulate most organs and blood vessels through the release of NE. A second SNS component is the collection of CCs within the adrenal medulla that, upon ACh and PACAP release from the splanchnic nerve, trigger the secretion of NE and EPI. CCs are also located in paraganglia close to large blood vessels and along sympathetic nerves that innervate pelvic organs (296, 366, 437). Finally, paraganglionic cells also include chemoreceptive type I cells of the carotid body, which are peripheral oxygen sensors.

Unique to the SNS is that a quite low firing frequency (less than 1 AP per second), is sufficient to maintain constant cardiovascular, respiratory, and metabolic functions of the body. Full activation during stress occurs when nerve fibers discharge at maximum rates equal or higher than 10 Hz (2, 50, 155, 515). The splanchnic nerve innervates the adrenal medullary CCs and is cholinergic. Through the release of ACh at the cholinergic-CC synapse, the human adrenal medulla secretes about 0.05 $\mu g\,kg^{-1}\,min^{-1}$ NE and 0.2 $\mu g\,kg^{-1}\,min^{-1}$ EPI (i.e. about 75% EPI and 25% NE), similar to the ratios reported in adrenal glands of cats, dogs, and calves (576). Thus, NE release from sympathetic nerve terminals throughout the body, and NE plus EPI release from the adrenal medulla maintains the basal circulating CA levels at about 250 and 100 $pg\,mL^{-1}$, (1.25 and 0.55 nM), respectively, for NE and EPI. This dual mechanism of stimulation represents a safety mechanism to maintain body homeostasis. The sympathetic neurons releasing NE locally at tissues they innervate and the adrenal medulla CCs releasing NE and EPI into the circulation augment the metabolic rate of practically every cell in the organism (250, 268).

Classical and modern histochemical, morphological, and functional studies have shown the existence of separate populations of NE- and EPI-secreting CCs in the adrenal medulla of mammals (140, 300, 456). The activity of these two cell subtypes seems to be regulated by separate neuronal pathways to the adrenal medulla. Nerve terminals on NE CC cells are morphologically distinct from terminals on EPI cells (259). Double-virus transneuronal labeling shows that the secretory activity of CCs is regulated by a set of neurons at the brainstem and the hypothalamus (323). Cumulative evidence supports the view that NE and EPI release from their respective adrenal medullary CCs is tightly regulated at three different levels, namely the brain, the spinal cord, and the CCs themselves. Thus, burst-pattern stimulation of the trigeminal nucleus caudalis in the cat brain stem preferentially releases EPI (59). The selective release of EPI is also regulated by autonomic areas in the cerebral cortex (648), hypothalamus (228, 540), and medulla oblongata (388, 438). Furthermore, the stimulation of other regions of the hypothalamus (228, 540) and medulla oblongata (438) selectively regulates the release of NE. This occurs probably because distinct preganglionic neurons innervate NE and EPI CCs (457). In addition, separate populations of preganglionic neurons, originating in different segments of the intermediolateral column of the spinal cord, differentially innervate CC subtypes, with the more cephalic preganglionic outputs innervating EPI cells and the more caudal ones innervating NE cells (187).

Thus, the different secretion of NE and EPI seems to be regulated by the distinct innervation of NE and EPI cells and

by the different input patterns that each cell type receives from the brain during stress. This may lead to selective recruitment of different subtypes of voltage-gated Ca^{2+} channels (Ca_V) expressed by CCs (240, 417). Thus, in two studies, different stimulation patterns caused differential secretion of EPI or NE; in bovine CCs stimulated with KCl, $Ca_V2.1$ (P/Q-type) channels were associated more tightly with EPI release, while Ca_V1 (L-type) channels were linked to selective NE release (400). The type of cholinergic receptor targeted by ACh may also condition the selective amine release; while nAChRs mediate the release of both CAs, muscarinic receptors preferentially mediate the release of EPI (173).

The differential secretion of NE and EPI may find a physiological and pathophysiological explanation in the different stressors or pathological situations that disrupt the organism's homeostasis. During the "flight-or-fight" response described by Cannon, an alarming acute stressful conflict causes a massive discharge of the sympathoadrenal axis, with the ensuing a large surge of NE and EPI release. Pupils and bronchioles dilate; heart rate, myocardial contraction, and blood pressure increase to switch blood to skeletal muscles that must increase the vigor of their activity; glucose is mobilized from muscle and liver to increase glycemia and metabolic activity is augmented in practically all cells of the organism. In this way, the organism is prepared as a whole to fight or run away from danger, two highly coordinated physiological responses.

From a pathophysiological perspective, the differential secretion of NE and EPI may also occur as a response to specific stressors (252). For instance, hemorrhage in cat causes a preferential release of NE, a situation in which vasoconstriction is required; however, insulin-induced hypoglycemia causes a selective EPI release because of its stronger capability to mobilize glucose from the liver (225). Other studies in the rat also demonstrate a preferential EPI release during hypoglycemia (597, 645). This contrasts with the preferential release of NE observed in rats exposed to cold stress (646). Histamine releases preferentially EPI through the activation of H1 receptors (68). Muscarinic stimulation also preferentially releases EPI (164).

Synthesis, Storage, and Metabolism of CAs

Synthesis and storage of CAs

Winkler and colleagues first introduced the concept of the "secretory cocktail" of CCs: the complement of proteins, peptides, cations, ATP, and CAs that are released from the CG as the major effector function of the CC of the adrenal medulla. Here, we describe briefly CA and protein/peptide biosynthesis and granule storage, as a necessary prelude to the more elaborate description of how this secretory cargo is released from the CC of the adrenal medulla to exert the unique physiological function of this essential endocrine organ.

The CA content of the CG depends on two processes: CA biosynthesis and CA vesicular transport and storage. The story of the discovery of the biosynthetic pathways of CAs is one of the most fascinating in neuroscience that, in spite of the enormous technical limitations was started in the latest 1930s of the past century. The detailed description of all the steps involved in the transformation of the amino acid tyrosine in the three natural CAs, DA, NE, and EPI, is beyond the aim of this article. A comprehensive description of the enzymes, cofactors, and kinetics associated with CA biosynthesis can be found elsewhere (647).

The adrenal medulla is the paradigm for the full CA synthetic pathway from the amino acid tyrosine to the final major CA product of the adrenal medulla, EPI. The conversion of tyrosine to DA occurs via the sequential actions of tyrosine hydroxylase (importantly, the rate-limiting enzyme in CA biosynthesis) to produce L-dopa and aromatic amino acid decarboxylase (AADC, a.k.a. dopa decarboxylase) to produce DA. DA is transported into the storage vesicle by vesicular monoamine transporters (VMATs) (see below) and converted to NE by DBH within the SG. Sequestration of DA into the SG accomplishes two important cellular goals: presenting DA to dopamine-β-hydroxylase (DBH) for its conversion to NE and removal of DA from the cytoplasm, where its metabolism by monoamine oxidase (MAO) creates potentially toxic oxidation products which, in the brain, have been implicated in the neurodegeneration of Parkinson's disease (293). The only synthetic step that must occur inside the CG is the conversion of DA into NE as DBH is an intragranular protein, in fact, one of the intragranular proteins that, along with CgA, helped to first establish the concept of exocytosis itself (62, 283). Once DA is converted to NE, NE diffuses from the SG and is converted in the cytoplasm to EPI [in cells that express the cytoplasmic enzyme phenylethanolamine-*N*-methyltransferase (PNMT)], which is then transported back into the CG and stored mainly in an osmotically inert compartment prior to exocytotic release. The proportion of NE/EPI varies depending on the species where it is measured; for instance, the proportion of EPI found in rats is around 90%, whereas this ratio drops to ≈73% in dogs, mice, and cows and 60% in cats and goats. The CA content of the human adrenal medulla is about 80% EPI. As described earlier in this article, EPI and NE are found mainly in separate CCs, that is most NE in PNMT-containing CCs is converted to EPI.

Almost all CAs are stored in CGs. This process occurs via transport by the VMAT. VMAT is at the heart of CC function because it is responsible for accumulation of EPI and NE into CGs at the concentrations required for hormonal action at distant targets, following exocytotic secretion into the general circulation. The free catechol concentration in the cytosol is 50 to 500 μM, comprising 10% CAs (458), while the measured concentration of catechols in CGs is 0.8 to 1.0 M, depending on the mammalian species (9, 454, 455). Thus, the CG concentrates CAs more than 10,000-fold against their concentration gradient, a thermodynamic feat whose accomplishment defines the function of the CC.

Understanding how VMAT transports CAs began with the work of Scarpa, Johnson, and colleagues (329, 330).

CA uptake and storage in CGs is a two-step process in which CA transport into the CG is followed by its osmotic inactivation via complexation with other granule components including ATP, chromogranins, and Ca^{2+} (282, 517, 629). To study the first process in isolation, workers employed CG ghost granules lysed to release their contents, and then resealed as empty vesicles (330). Accumulation of CAs into these "ghosts" was the model system in which Scarpa and Johnson worked out the now-famous formula for CA transport via proton exchange, where the proton-motive force $\Delta p = \Delta\Psi - [2.30\ RT/F \times \Delta p\mathrm{H}]$, with proton-motive force generated by the vacuolar ATPase of the CG membrane (331). The laboratories of Schuldiner and Henry made seminal contributions to the pharmacological characterization of amine uptake in the granule "ghost" system, identifying the approximate molecular weight of the transporter via reconstitution and explaining the amine-depleting effects of reserpine and tetrabenazine based on their inhibition of CA transport. It was deduced that there were two forms of VMAT—now known as VMAT1 and VMAT2—based on the universal uptake-inhibition properties of reserpine, but the species and tissue-specific inhibition by tetrabenazine (for reviews, see Refs. 286 and 559). The uptake of quaternary amines such as the Parkinsonogenic MPP+ confirmed the likelihood of amine transport through the carrier as a positively charged species (559). All of these pharmacological properties were used to allow the eventual cloning of VMAT1 and VMAT2 cDNAs in *in cellula* expression systems (208, 393). VMAT1 and VMAT2 are expressed in all mammalian species, while *Caenorhabditis elegans* contains only one VMAT, with the properties of VMAT2 (uptake of histamine and inhibition by tetrabenazine). This suggests that the evolutionary selection of the properties of VMAT1 allows it to function as a selective transporter for serotonin, to the exclusion of histamine, in the enterochromaffin cells of the gut that supply serotonin for utilization as a neurotransmitter in the enteric nervous system (179). Although VMAT1 was originally characterized as the "endocrine" VMAT and VMAT2 as the "neuronal" VMAT (664), the CG contains VMAT1, VMAT2, or both VMATs, depending on species and (in the rat), on the state of stress of the organism. Immobilization stress causes an upregulation of VMAT2 expression in the rat adrenal medulla, mainly within EPI cells (616). VMAT2, however, is the exclusive transporter for CAs in the CNS (209, 210). VMAT is a structurally highly conserved protein across species—both isoforms possess twelve vesicular membrane-spanning domains, with the residues contributing to specificity for histamine located to several discrete regions within the transporter that contributes to an amine-binding domain (226). The essential proton-exchange function of the VMATs is found even in bacterial proton antiporters, leading to the inclusion of the VMATs in an evolutionarily distinguishable superfamily called the toxin-extruding antiporters (TEXANS). This suggests that amine uptake into vesicles is a coopted function of toxin extrusion from single-celled organisms (560), and presaging the function of VMAT2 as a "vesicle-sequestering" protein protecting CA-containing CCs, as well as dopaminergic neurons, from oxidative damage caused by CA metabolites resulting from CA degradation by MAO and other oxidative enzymes (253).

The parallel process of biosynthesis and storage in SGs for the protein and peptide exportable products of the CC is discussed later. Synthesized as the so-called preprohormones in the rough ER, proteins of the SG are imported into the granule through the trans-Golgi network (TGN) and condensed into nascent CGs at that location through a process that is still ill-defined (312). The CC has been a model system for understanding the role(s) of proteolytic converting enzymes (PCs) as well as "trimming" and amidating enzymes in the production of bioactive peptides in neuroendocrine cells. For an overall historical perspective, see Ref. 672; for prohormone convertases, see Ref. 459; for carboxypeptidase processing enzyme (CPE), see Refs. 307 and 231; and for peptidylglycine α-amidating monooxygenase (PAM), see Ref. 192.

An important factor that largely contributes to the accumulation of amines is the vesicular ATP. ATP is present, and highly concentrated, in almost all secretory vesicles from all animal species (67). Although its physiological role in the concentration of CA was suggested since the 1960s and demonstrated *in vitro* (361, 603), it was not easy to test its role *in vivo*, as the removal of cellular ATP would mean the death of the cell. However, the cloning of the vesicular nucleotide transporter (VNUT, Figure 9) by the group of Moriyama (554) allowed the study of the contribution of vesicular ATP in the accumulation of CA. Thus, using siRNA against VNUT, Estevez-Herrera and collaborators demonstrated that the reduction of vesicular ATP largely reduced the accumulation of CA (214).

The result of amine uptake and storage, protein processing, and the collaboration of granins, ATP and Ca^{2+} in the production of the SG core is the "secretory cocktail" of the adrenal medulla: proteins, bioactive peptides, and small molecules, including CAs, GABA, and ATP that are released upon depolarization of the CC. The remainder of this article describes the molecular, cellular, and system biology of how the release of this secretory cocktail, via hormonal, neuronal, and inflammatory first messengers, affects mammalian organisms in both normal and pathophysiological states.

Metabolism of CAs

Two different mechanisms terminate CA activity: active cell membrane transporters and metabolizing enzymes. The final disposal of CAs and their metabolites is achieved by renal excretion. In neurons, 90% of released NE is taken back up into the cell by the NE transporter at the presynaptic membrane (193), while EPI released from the adrenal medulla is removed from the circulation by nonneuronal monoamine transporters (198). CAs taken up into neurons or CCs can either be metabolized by intracellular enzymes or sequestered into storage vesicles (194). Sympathetic neurons and CCs, contain monoamine oxidase (MAO), whose

principal substrates are, as the name implies, the CAs DA, NE, and EPI. The major deaminated metabolite of NE is 3,4-dihydroxyphenylglycol (DHPG) (194). The adrenal medulla contains catechol-*O*-methyltransferase (COMT). This enzyme is responsible for the intramedullary conversion of EPI into metanephrine and NE into normetanephrine (198). Over 90% of metanephrine and about 23% of normetanephrine in circulation are formed within the adrenal medulla from CA leaking from granules into the cytosol (198). The remainder of the circulating metanephrine derives from extra-adrenal metabolism by COMT after adrenal release of EPI.

Chromaffin Cell Excitability

What makes CCs excitable? The ion channels controlling the resting potential and action potential generation in CCs

As explained above, adrenal CCs release CA into blood circulation in response to sympathetic stressful stimuli. Typically, CA secretion is regulated neurogenically by the activity of the splanchnic nerve whose nerve terminals in the adrenal medulla release ACh sufficiently close to CCs to induce postsynaptic responses well above the threshold to activate *all-or-none* APs (303). This excitatory response is associated with the activation of nicotinic excitatory postsynaptic currents (48, 304, 334) that cause cell depolarization and AP trains of the same frequency as splanchnic nerve stimulation, with no evidence of fatigue or desensitization when stimulated at low rates (0.3–3 Hz) (303). In this way, CCs act as "relay elements." They couple splanchnic nerve activity to CA secretion by generating AP trains that trigger Ca^{2+} entry through voltage-gated Ca^{2+} channels and regulate the Ca^{2+}-dependent cascade of events leading to neurotransmitter release.

To accomplish this task, CCs contain a "palette" of ion channels that is as rich as that found in neurons (389), appearing even excessive for a "relay element" that should passively follow the neural input. Despite the central importance of neurogenically evoked release of CAs (155), it is possible that the ion channel "palette" can also sustain an *intrinsic electrical activity* of CCs that, under humoral conditions, may contribute to characteristic forms of CA secretion. Consistent with this, recent work on mouse models reveals that mouse CCs exhibit several voltage patterns of intrinsic excitability, including a slow-wave burst activity that may be significant for CA secretion (12, 260, 263, 426, 434, 633).

In this section, we will describe all the ion channels expressed by CCs that contribute to the resting membrane potential and generate the patterns of APs and slow-wave burst activity under physiological and pathological conditions. Table 1 summarizes all the ion channels that will be described and that are proposed to play specific roles in the function of CCs.

Na^+ channels (Nav1.3 and Nav1.7)

CCs of most mammalian species exhibit robust voltage-dependent Na^+ (Nav) currents (222, 407, 633) that are entirely tetrodotoxin (TTX)-sensitive. Na^+ currents in CCs start activating at around −35 mV and reaches maximal amplitude at −10 mV in 2 mM extracellular Ca^{2+}. They activate in less than 1 ms and inactivate quickly within 5 ms at 0 mV. At this potential, the AP reaches its maximal rate of rise (dV/dt_{max}) and decay ($-dV/dt_{max}$) before and after reaching its peak amplitude between +20 and +40 mV in mouse CCs (51, 633). Recovery from full inactivation of Nav channels is relatively fast and complete at −90 mV (90% in 100 ms) and at resting potentials of −50 mV (70% in 100 ms) (633). In this way, the Nav channels of CCs are designed to sustain the fast response to sympathetic nerve stimulation repeated at its maximal rate of 20 Hz with no decay of AP amplitude (303).

Na^+ currents in CCs have been reported to be carried by Nav1.7 channels (358, 654, 655), but evidence on this point is incomplete. Recent work, using quantitative PCR and western blots, suggests a contribution of both Nav1.3 and Nav1.7 in MCCs, with a preponderance of the Nav1.3 isoform (633). However, the voltage dependence of both activation and steady-state inactivation of mouse Nav currents is consistent with one type of sodium channel (633). Based on the studies of heterologously expressed Nav1.3 and Nav1.7, both channels share similar functional properties, but the voltage at which Nav1.3 is half inactivated is shifted to the right compared to that for Nav1.7 (146, 297, 638). Thus, if both isoforms are expressed in mouse CCs in similar proportions, the Nav currents should exhibit double rather than single Boltzmann inactivation functions. However, this is not the case in either rat or mouse CCs (633). Thus, Nav currents seem most consistent with a dominant Nav1.3 channel in MCCs. Indeed, preliminary results using Nav1.3 KO mice confirm that Nav current is completely lost in MCCs (Chris Lingle, personal communication) (389). Interestingly, Nav1.3 channels have strong structural homologies to Nav1.1 and Nav1.2, which are the Nav channels of brain neurons implicated in AP initiation, AP conduction, and repetitive firing (117).

Ca^{2+} channels (Cav1, Cav2, and Cav3)

Following the early patch-clamp recordings of voltage-dependent Ca^{2+} currents (32, 222, 309), the gating properties, pharmacological diversity, and modulation of these currents in CCs have been the subjects of extensive investigation using different CC species (7, 30, 31, 35, 36, 74, 98, 103, 121, 136, 236, 404, 406, 411, 417, 419, 427, 484, 495, 509, 510, 542, 575, 634). Nearly all known subtypes of high-voltage-activated Ca^{2+} current, including Cav1 (L-type) and Cav2 (P/Q-, N-, and R-type) channels have been described in rat (523), mouse (11, 417), cat (7), cow (30, 411) and human (510) CCs. Cav3.2 T-type Ca^{2+} channels are also expressed, particularly during immature stages and stressful conditions preserving their particular low-voltage range of activation

and fast-inactivating kinetics in rat and mouse CCs (74, 103, 107, 108, 298, 379, 479).

The expression density of Cav channels varies remarkably among animal species studied (human, bovine, pig, cat, mouse, and rat; 224), cell conditions, and development. In adult animals, L-, N-, P/Q-, and R-type channels are the dominant species (240, 262, 426, 427). They shape AP waveforms and regulate CA secretion and vesicle retrieval. Despite the many reports, there is still no convincing proof of a specific colocalization of any of the expressed Cav channel subtypes with the secretory apparatus. Each channel type controls CA release with the same linear Ca^{2+}-dependence (30, 100, 103, 206, 248, 352, 417, 543, 609, 627). Why do simple relay elements like CCs need so many different Ca^{2+} channel types for their task? A possibility is that depending on their different sensitivity to voltage, external signaling, and intracellular second messengers, the many expressed Cav channel types (see Table 1) permit compensatory paracrine and autocrine responses to regulate the proper CA release during different CC functioning conditions. The large number of Cav channels also derives from the dual role (chemical and electrical) that Ca^{2+} channels exert in the control of both CA release and AP firing (426, 631, 632).

Cav channel contributions to AP firing are conditioned by the voltage dependence of activation of the different Cav channel isoforms. Cav2.1 (P/Q-), Cav2.2 (N-), and Cav2.3 (R-type) channels activate at significantly more positive voltages than Cav1.2 and Cav1.3 (L-type) channels and therefore contribute mostly to the fast AP upstroke. Cav1.2 and Cav1.3 channels activate at more negative potentials and thus contribute to the slow phase of depolarization between consecutive APs (interspike potential). It is also important to notice that L-type channels are expressed at high densities in CCs. They inactivate slowly and carry about half of the total current in mouse, rat, and cat CCs (46, 121, 240, 428) and, most likely, also in human CCs (see Ref. 631). For this reason, they pass sufficient currents at very negative potentials and are thus favored to set the "pacemaking" current regulating the repetitive AP firing of CCs near resting potential. Looking more closely at the biophysical properties of these two L-type

Table 1 Na^+, Ca^{2+}, and K^+ Channel Types Expressed in CCs

Current	Channel type	Function	Animal	References
INa	Nav1.3	AP upstroke	Mouse	(389, 633)
	Nav1.7		Rat	(358, 654, 655, 681)
ICa	Cav1.2 (L)	AP upstroke, pacemaking, neurosecretion	Mouse, rat, bovine, human	(46, 429)
	Cav1.3 (L)			(429, 632, 635)
	Cav2.1 (P/Q)	AP upstroke, neurosecretion	Mouse, rat, bovine, human	(12, 30, 35, 240, 418)
	Cav2.2 (N)			(12, 30, 35, 240, 418)
	Cav2.3 (R)			(11, 121, 418)
	Cav3.2 (T)	AP threshold, neurosecretion	Mouse, rat	(104, 107, 427)

	Kv11 (ERG)	V_{rest}, AP repolarization	Mouse, rat	(263)
IK_{ATP}	Kir6.1 Kir6.2	V_{rest} repolarization during hypoxia	Rat	(73, 550)
IK	K2P (TASK)	V_{rest}, pH sensitive	Mouse, rat	(260, 316)

channels, it appears evident that Cav1.3 possesses the proper parameters to act as a pacemaker channel. Data derived from heterologously expressed channels indicate that (i) Cav1.3 activates with steeper voltage dependence and at more negative voltages than Cav1.2 (362, 679) and (ii) Cav1.3 has slower and less-complete voltage-dependent inactivation as compared to Cav1.2 (362).

Given the lack of specific blockers for either Cav1.2 or Cav1.3 (both are nifedipine-sensitive) in CCs, the dominant role of Cav1.3 as a pacemaker channel could only be revealed using the Cav1.3 KO mouse ($Cav1.3^{-/-}$) (516). Previous studies on the role of L-type channels in CC pacemaking showed that these channels could pass 10 to 20 pA of current in WT MCCs at rest, and nifedipine could either decrease the firing frequency or block the spontaneous firing (426, 428). A subthreshold inward Ca^{2+} current of this size passing through the high input resistance of CCs (3–5 GΩ) (222, 428, 429) is sufficient to generate pacemaker potentials of 10 to 20 mV in amplitude to drive the cell from resting (−50 mV) to the threshold of the AP upstroke (~−30 mV). Deletion of Cav1.3 drastically reduces the amplitude of this pacemaker current and the fraction of MCCs firing spontaneously (429). Loss of Cav1.3 (i) decreases markedly the level of the nifedipine-sensitive currents driving spike generation, (ii) raises the rheobase (the minimal amount of current required to elicit a train of APs) from 4 to 6.6 pA, and (iii) decreases the extent of spike frequency adaptation during sustained current injections (635). In conclusion, Cav1.3 in CCs plays a key role in the control of AP firing either spontaneous or evoked during step depolarization. Compared with other neuronal pacemaker channels that carry mostly Na^+ currents, like the hyperpolarization-activated cation channels (HCN) (502), the persistent (143) and resurgent (527) Na^+ channels, and background channels (409), Cav1.3 appears unique and worthy of being further studied in cardiac cells and brain neurons.

Ca^{2+}-dependent SK and BK potassium channels

CCs were among the first cells from both rat and cow in which Ca^{2+}-dependent small- and big-conductance (SK and BK) potassium currents were recorded (29, 408, 434, 436, 467, 468). SK currents are voltage independent and blocked by the bee-venom toxin apamin (319). They activate robust outward currents following the release of cytosolic Ca^{2+} stores (467). Single SK channels have small K^+ conductance and are half activated at ~0.7 μM cytosolic Ca^{2+} (503). Mouse CCs express all the identified SK channel subtypes: SK1, SK2, and SK3 (635). SK are open at any potential if sufficient cytosolic Ca^{2+} is available, and therefore they contribute to setting the CC resting potential. Their current builds up between successive APs and sets the basal frequency of spontaneous repetitive firing. In fact, block of SK channels by apamin usually increases the spontaneous firing rate of CCs, suggesting that there is sufficient SK activation between spontaneous APs to prolong the interspike interval (ISI) (635). SK channels respond to small and persistent increases in cytosolic Ca^{2+} (218). In this way, they play a negative feedback role in response to Ca^{2+} influx and set the firing frequency in resting CCs. SK currents build up markedly during high-frequency firing or prolonged bursts and help terminate the firing or the burst (635). More specifically, SK channels are the main K^+ channel types that activate near rest, which is with mild depolarization, or during the ISI, with a degree of activation proportional to the amount of Ca^{2+} entering the cell during the repeated APs or a burst. In this way, SK channels act as an effective "brake" on firing cells, to promote more regular firing and adapting the AP for constant maximal amplitude during sustained cell activity.

BK channels are voltage dependent. They activate following cytosolic Ca^{2+} elevation, but their probability of opening depends on the degree of cell depolarization. BK channels are also less sensitive to Ca^{2+} with respect to SK, requiring ≥10 μM cytosolic Ca^{2+} to be activated (218). Given the diversity and multiplicity of intracellular Ca^{2+} buffering systems, and their tight regulation, such high concentrations occur only within Ca^{2+} "nanodomains" near Ca^{2+} sources, that is in the vicinity of Cav channels (218). This implies that BK channels are localized near a Cav channel, and usually they are colocalized with more than one Cav channel (522, 632). In CCs, upon sufficient Ca^{2+} elevation and depolarization, the BK current is typically the most prominent outward current in CCs of all mammalian species (408, 429, 434, 468). This greatly conditions the shape of single APs that exhibit a marked afterhyperpolarization (AHP) during the falling phase of the action potential, depending on the number of BK channels open upon cell repolarization. In CCs, BK currents can be either inactivating (BK_i) or noninactivating (BK_s) (429, 434, 468, 522) in varying degrees, from completely inactivating to completely noninactivating.

BK channel inactivation rate in CCs depends on the presence of a regulatory β2 subunit (661, 676) whose cytosolic N-terminus mediates a pore occlusion type of inactivation (677). Genetic ablation of β2 subunit expression results in complete loss of inactivation of BK current in mouse CCs (434). The functional role of BK channel inactivation *per se* remains unclear (598). BK channel inactivation is very slow (>35 ms, when 2 β2 subunits are bound to the channel); thus, during trains of APs at 10 Hz, there is little cumulative BK channel inactivation (167, 434). However, besides producing inactivation, the regulatory β2 subunit also shifts the range of channel activation to more negative voltages (676). With a full set of four β2 subunits bound, the activation of BK channels shifts by about 60 mV to more negative voltages with 10 μM cytosolic Ca^{2+}. This shift is critical for the effective range of channel gating and results in different AP firing patterns between CCs with BK_i or BK_s currents (434, 581, 598). In the absence of any β2 subunit bound, BK channels will activate less at a given Ca^{2+} (434), causing an increased AP amplitude, slowed AP repolarization, and reduced AHP. This, in turn, slows the rate of recovery of Nav channels from inactivation and reduces the contribution of Nav channels to the next AP. This, eventually, results in AP

block after sufficient cumulative Nav inactivation (390). How these properties of BK channels affect burst firing will be considered in the following sections.

Voltage-dependent Kv (Kv1–3, Kv4, Kv7, and Kv11), K_{2P} TASK, and K_{ATP} potassium channels

CCs express a variety of voltage-gated Kv channels that mainly control the resting potential, the AP repolarization phase, and the mode of AP firing (tonic vs. burst) of the cells. Bovine rat, and mouse CCs express Kv currents that are either slowly (Kv1–3) or rapidly inactivating (Kv4; I_A current) (429, 436, 468, 564). Kv4 currents are prominent in bovine CCs and possess activation/inactivation characteristics that suggest that they may play a key role in the regulation of repetitive AP firing frequency during sustained stimulation (564).

CCs also express Kv7 (KCNQ; M-currents) and the Kv11 (ERG) channels. Kv7 is highly expressed in cardiac cells, postganglionic sympathetic neurons, and brain and blocked by mAChR activation through a membrane-delimited PIP_2 depletion mechanism mediated by Gq/PLC-β [for review, see (161)]. Kv7 are "low-threshold" K^+ channels that are already open at rest, activate very slowly with membrane depolarization, and do not inactivate during prolonged depolarization. In bovine CCs, there is evidence of an M-current inhibited by histamine (660). The existence of Kv7 in CCs, along with mAChRs, suggests a role for Kv7 channels in cell depolarizations induced by mAChR activation. However, data on this issue do not lead to a firm conclusion on this point (489). This derives most likely from the existence of different isoforms of mAChRs and different coupling to Kv7. In MCCs, muscarine causes either hyperpolarization plus a depolarization (31%), a depolarization alone (30%), hyperpolarization alone (21%), or no effects (18%). In contrast, blockade of Kv7 channels by XE991 causes a sizeable depolarization in 100% of the cells, followed by an increased firing frequency or a switch of spontaneous firing from tonic to bursts (402) (I. Méndez-López, A.G. García, and E. Carbone, unpublished observations). ERG or Kv11 channels have been identified in rat CCs (263). Block of Kv11 by the selective blocker WAY-123,398 causes marked cell depolarization, increased spontaneous firing frequency, and even burst firing in some cases, indicating that Kv11 channels may have an important role in regulating CC excitability (263).

Rat and mouse CCs also express the pH-sensitive K^+ channels TASK-1 and TASK-3 that are two-pore "leak" channels (K_{2P}) contributing to the membrane potential and firing activity of cells at rest (260, 316). In rat CCs, TASK-1 channels are blocked by the activation of mAChRs, and thus are postulated to be targets of the mAChR stimulatory action that leads to increased CA secretion (316). In mouse CCs, blockade of TASK-1 channels by the selective blocker A1899 and BK channels by paxilline mimics the effect of lowering the extracellular pHo causing cell depolarization, burst firing, and increased CA release (260). Given the expression of TASK channels, MCCs act as "pH sensors" which trigger an effective physiological response that compensates for the acute acidosis and hyperkalemia generated after vigorous exercise and muscle fatigue (441).

CCs also express K_{ATP} (Kir6.1 and Kir6.2) channels (73, 375, 550, 615). As in other cells, these channels are expressed to protect the cell during low O_2 pressure (PO_2) conditions that lower cytoplasmic ATP. In rat CCs, K_{ATP} channels are effectively activated during acute hypoxia, most likely due to the transient reduction of ATP at low PO_2. The involvement and upregulation of these channels is evident in rat CCs when acute hypoxia is tested in the presence of the K_{ATP} channel blocker glibenclamide. The addition of glibenclamide has no direct effect on K^+ current but enhances the inhibitory action of acute hypoxia on K^+ currents (550), suggesting that K_{ATP} channels are recruited only in response to low O_2.

The neuron-like spontaneous action potentials: tonic versus burst firing

In CCs, like in neurons, spontaneous firing takes place when sufficient inward current is driven by small voltage perturbations near resting potential. Critical for triggering spontaneous AP oscillations is the net balance between inward (leak, Na^+, and Ca^{2+}) and outward K^+ currents near resting potential. When the inward depolarizing current exceeds the outward current, a more positive unstable potential is reached at the start of the "negative conductance" region of the IV characteristics (680). At this unstable potential, any small depolarization causes a small inward current that depolarizes the cell further and triggers a train of APs. Subthreshold spontaneous membrane potential oscillations occur easily if the cell possesses high input resistance (3–5 GΩ) and is equipped with sufficiently large densities of Nav and Cav channels that activate readily at low voltages as in CCs (222, 418, 428). An additional critical requirement for driving spontaneous APs in slowly firing cells (~1 Hz) is the presence of a weakly inactivating inward current that sustains the slow pacemaker potential. Spontaneous firing is rather variable in CCs regardless of whether the cells are isolated and plated in culture or in adrenal gland slices (for a review, see Refs. 389 and 631). In many CCs, the repetitive firing is "irregular," that is spikes occur at a variable frequency (Figure 1A). In mouse CCs, the degree of regularity is somehow correlated with spike frequencies. Fast spiking cells are typically more tonic and display "regular" repetitive firings (Figure 1B).

As in neurons, a small fraction of CCs can also undergo spontaneous bursts at normal physiological conditions (434, 633). Burst firing occurs as trains of APs on top of a sustained plateau potential of variable duration (Figure 1C). The burst terminates with a robust AHP whose amplitude sets the duration of the ISI. Deeper AHPs generate longer ISI. The origin of this "neuron-like" bursting mode in CCs is largely unknown, but one can speculate that it derives from a combination of accumulated BK- and Kv-channel inactivation and sizeable slowly inactivating Na^+ and Ca^{2+} currents that sustain the plateau potential and part of the spike amplitude.

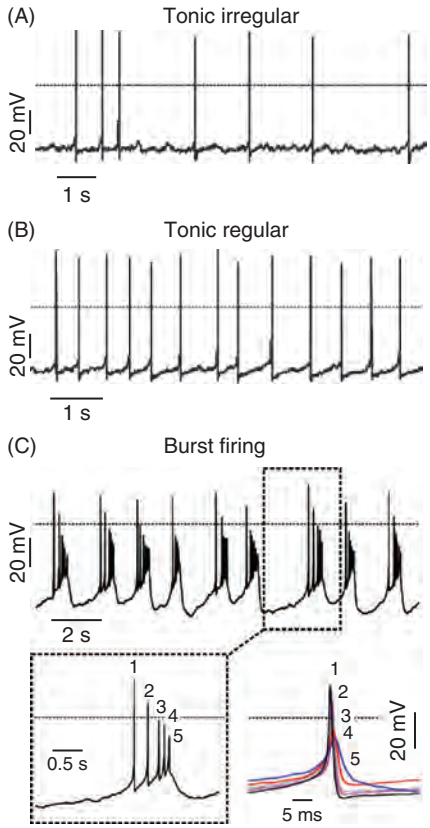

Figure 1 Different firing modes of spontaneously active chromaffin cells. (A, B) Spontaneous AP trains recorded from two different rat CCs displaying "irregular" and "regular" tonic firings, respectively. (C) Spontaneous AP trains exhibiting slow-wave bursting recorded from a mouse CC. Below is shown a single burst at an expanded time scale (dashed rectangle) and the overlap of consecutive APs within a burst. Numbers indicate the sequential position in the burst. Adapted, with permission, from Vandael DH, et al., 2015 (633).

Any reduction of the K^+ currents activated during the first AP attenuates the AHP to less negative values (plateau potential) where Cav and Nav channels can sustain the series of AP during bursts. Several ion channels contribute to set the plateau potentials and spike amplitudes. The key issue is to uncover how the degree of expression, gating properties, and sensitivity to endogenous and exogenous modulators of these channels may alter the equilibrium between repetitive and burst-firing modes in CCs.

Tonic firing in CCs

The first intracellular and extracellular recordings of spontaneous firing activity in rat CCs were reported almost 50 years ago (61, 76). In these studies, the emphasis was on the identification of the current components that participate in nerve-evoked depolarization and could influence the Ca^{2+} influx required for CA secretion. Subsequent reports confirmed that CCs can generate APs when stimulated and that they fire spontaneously both *in situ* or when isolated from the glands (47, 263, 467). In some cases, they exhibited considerable rhythmic complexity suggestive of bursting (263). The existence of a spontaneous (nonneurogenic) firing activity was compelling and received strong experimental attention. The leading idea was to identify the resting currents that control the timing of repetitive AP firing, after having observed that the block of L-type channels by 3 µM nifedipine reduced or fully blocked the spontaneous activity of mouse CCs (426, 428). Given this, the primary issue was to determine whether the slowly inactivating Cav1.3 channel was the main L-type channel responsible for the spontaneous firing activity. This could be done using the Cav1.3 KO mouse generated by the Striessnig laboratory (516). By comparing the ionic conductances and firing properties of WT and Cav1.3 KO mice, it was possible to show that both a Cav1.3-mediated inward current and a BK-mediated outward current are active during the interspike interval and the initial rising phase of an individual AP (429). The two currents balance each other with a slight predominance of Cav1.3 that drives the spontaneous firing. The time course of the subthreshold inward Cav1.3 current became evident in WT cells after blocking BK channels with 1 µM paxilline or 5 mM TEA, while this current was clearly absent in Cav1.3 KO cells.

A dominance of subthreshold Cav1.3 currents in regulating AP firing is also evident when studying their functional coupling with SK currents and how the coupling effectively adapts sustained AP trains during prolonged cell depolarizations. The Cav1.3-dependent SK currents that build up during the interspike intervals in WT cells lead to spike frequency adaptation that is strongly attenuated in Cav1.3 KO cells (635). Low adaptation ratios due to reduced SK channels activation associated with Cav1.3 channel deficiency prevent the effective recovery of Nav1.3 channels from inactivation. This promotes a rapid decline in AP amplitudes and facilitates early onset of depolarization block following prolonged stimulation. Thus, in Cav1.3 KO mice, both the spontaneous and evoked AP firing are significantly altered.

The involvement of Cav1.3 in regulating AP firing in mouse CCs is also supported by the altered firing properties observed in mutated CCs in which the C-terminal automodulatory (CTM) domain is interrupted with a hemagglutinin tag (556). The CTM domain regulates the Ca^{2+}-dependent inactivation (CDI) of the channel and the replacement of the "distal C-terminal regulatory domain" (DCRD) with an HA-epitope generates a mouse ($Cav1.3DCRD^{HA/HA}$) that displays faster CDI. Indeed, the mutated CCs exhibited L-type currents with faster inactivation and reduced CDI. Spontaneous cell firing was significantly altered. An increased percentage of cells lost their spontaneous activity due to their more negative resting potential (silent cells), and evoked AP bursts had increased firing frequency due most likely to the reduced number of SK channels activated by the accelerated CDI of $Cav1.3DCRD^{HA/HA}$ channels (556). In conclusion, łoss or mutations of Cav1.3 channel gating induce significant changes in the spontaneous and evoked CC activity, suggesting a key role of these L-type channels in the generation and maintenance of AP firing.

Slow-wave bursting in CCs

Slow-wave bursting activity is an intrinsic firing pattern that can be recorded in 15% of WT MCCs either grown in culture (633) or in adrenal medulla slices (434). Burst firing may become dominant when CCs need to release CAs to sustain several physiological responses such as acute acidosis and hyperkalemia during heavy exercise and muscle fatigue (441) (see below).

AP bursts have variable shapes. In general, an initial AP of usual amplitude exhibits a slow and reduced repolarization. The slow repolarization leads to a depolarized plateau potential upon which a series of truncated, presumably Ca^{2+}-dependent secondary, APs develops before terminating with a strong repolarization. The number of secondary APs varies from burst to burst, but it is likely the amplitude and duration of the plateau potential that determines the amount of Ca^{2+} entry during the burst. Given that a slow-wave bursting lasts more than 300 ms and the plateau potential varies between −30 and −20 mV, the quantity of Ca^{2+} entering a cell is likely to be more than an order of magnitude larger than the Ca^{2+} entering during a single AP. This is far more than the Ca^{2+} entering by simply increasing the frequency of firing from 1 Hz to its maximal value (20–30 Hz). This implies that any cell manipulation, ion channel blocker, or channel agonist able to switch the spontaneous firing of a CC from tonic to bursting can induce a significant Ca^{2+} overload that boosts massive CA release during stress or perhaps some ongoing pathological condition (i.e. hypertension). In this view, an increased percentage of burst-firing CCs could be a marker of an increased functionality or a pathological state for the adrenal CCs.

It is of key importance to understand how Na^+, K^+, and Ca^{2+} channels contribute to the generation of slow-wave bursting. Figure 2 shows the time course of Nav, Cav, Kv, BK, and SK currents during burst firing using as voltage-clamp commands three different AP bursts previously recorded in current clamp (see Ref. 633). It is evident that Nav, BK, and Kv currents are maximal during the first and second AP, while they decrease rapidly during the remaining APs (Figures 2A, 2B, and 2D). At the end of the burst, their contribution falls drastically. Quite different is the time course of inward Cav currents that decreases slowly during the burst but keep contributing significantly to Ca^{2+} entry almost up to the end of the burst (Figures 2C and 2D). Conversely, the SK currents build up progressively during the burst to reach a critical size that terminates it (Figures 2C and 2D).

Recent studies have highlighted cell manipulations that enhance or unmask this slow-wave burst (260, 434, 633). In one case, reducing Nav1.3 channel availability by either slow depolarizations that induce partial Nav channel inactivation or application of low concentrations of TTX to reduce the number of active Nav1.3 channels unmasked bursting activity (633). In the second case, when the β2 auxiliary subunit of BK channels is genetically deleted, almost all CCs exhibit repetitive slow-wave bursting which occurs at a frequency (~1 Hz) similar to the spontaneous AP frequency of WT cells (434). In the third case, lowering of extracellular pH (pHo) from 7.4 to 6.6 causes a marked cell depolarization that induces sustained slow-wave bursts (Figure 3) and a nearly sevenfold increase in CA secretion. Cell depolarization is attributed to the blockade of pH-sensitive TASK and BK channels (260). As summarized in Table 2, burst firing is also induced when Kv7 channels are blocked by histamine (660), Kv11 channels are blocked by their specific blocker WAY-123,398 (263), and Kv, SK, and BK channels are blocked by acute hypoxia (550). Burst firing is also induced in mouse CCs when Kv and BK channels are blocked by TEA (464) and when Cav1 channels are potentiated with the selective agonist Bay K 8644 (260). There is also evidence that the pronounced depolarization

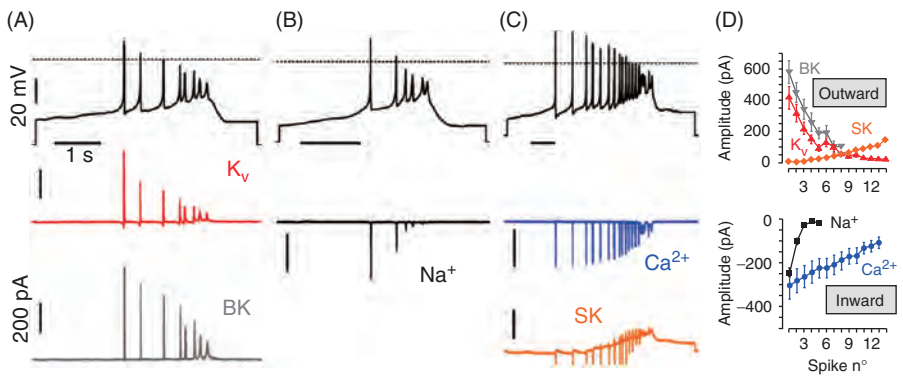

Figure 2 Time course of Na^+, Ca^{2+}, and K^+ currents during slow-wave bursts in mouse CCs. (A) AP-clamp experiment measuring Kv and BK currents. Top: AP bursts elicited by current steps were recorded at current-clamp mode and used as voltage command (black trace) in voltage-clamp experiments. Bottom: Kv currents are shown in red and BK currents in gray. (B, C) As in (A), but the currents isolated were Ca^{2+} currents (blue), SK (orange), and Na^+ (black). (D) Top: BK, SK, and Kv outward current amplitudes versus the spike number of the burst. Bottom: Same, but for the Na^+ and Ca^{2+} inward currents. Figure 3 Low pHo induces burst firing in mouse CCs. Spontaneous firing (no current injection) recorded in mouse CCs at pHo 7.4, 7.0, and 6.6. Bottom: AP recordings on an expanded time scale corresponding to the gray window above. A decrease in pHo results in resting membrane depolarization and the switch of firing modes from tonic (pHo 7.4) to mildly bursting (pHo 7.0), to sustained bursting (pHo 6.6). Intermittent and sustained burst firing are accompanied by a net decrease of AP peak amplitude associated with the slow inactivation of Nav1.3 channels at depolarized potentials. The dotted line indicates the 0-mV level. Adapted, with permission, from Guarina L, et al., 2017 (260).

induced by 10 µM muscarine drives the spontaneous firing of a large percentage of mouse CCs into a slow-wave bursting mode (I. Méndez-López, A.G. García, and E. Carbone, unpublished results).

Burst firing occurs typically when CCs are either depolarized by blockade of Kv, SK, TASK, or BK channels or when Cav1 channels are potentiated. In the first case, Nav1.3 channels are steadily inactivated by the sustained cell depolarization and are thus unable to activate a sufficient number of BK and Kv channels to produce marked AHP that warrants the fast recovery of Nav1.3 and Cav channels from their inactivation and the generation of the next AP. In the second case, the increase of slowly inactivating Cav1 currents is sufficient to produce enough inward current to sustain the plateau potential of the burst. It seems likely that other cases of channel modulation or cell manipulation that induce bursting will be discovered, to join those listed in Table 2.

Action potentials elicited by current injection

The ability of CCs to generate different patterns of spontaneous firing is helpful in understanding the causes of altered CC excitability and identifying the molecular targets that are altered. In some cases, CCs do not fire spontaneously (for a review, see Ref. 155), and when it does occur, spontaneous firing never reaches the high-frequency levels obtained during intense sympathetic stimulation (20–30 Hz). In addition, detailed analysis of CC firing during sustained high-frequency sympathetic stimulation is often required to obtain a more physiological view of stimulation-secretion coupling (153). In these cases, an alternative to recording spontaneous firing is to elicit trains of APs by applying step depolarizations of increasing current amplitude (2–20 pA) and variable length (0.1–10 s) to induce AP firing of increasing frequencies. Using current steps above 2 to 4 pA, CCs from all animal species examined undergo AP firing and CA secretion, confirming

Table 2 Cell Conditions, Hormones, Neurotransmitters, Blockers, and Agonists That Induce Slow-Wave Bursting in CCs

Stimuli, compound	Action on channels	Intensity of depolarization	Animal	References
Cell depolarization	Slowly inactivated Nav1.3	+++	Mouse	(633)
TTX	Block of Na1.3	+	Mouse	(633)

WAY-123,398	Block of Kv11 (ERG)	++	Rat	(263)

that CCs, like neurons, are highly excitable cells whose firing frequency controls Ca^{2+}-dependent CA secretion (303).

Evoked AP firing with step depolarization was first recorded 40 years ago (61, 76) using sharp glass microelectrodes. With the advent of the patch-clamp technique, evoked AP firing was detected in CCs of many animal species with variable results (153). AP recordings were used to identify the ion channel types involved in CC excitability (389). As in neurons, the analysis of AP trains with increasing step depolarizations furnishes a detailed view of the ion channels involved and their role in sustaining the firing. Well-resolved recordings of current-evoked AP firing have been reported in cow (153), rat (178, 581, 689), and mouse CCs (244, 434, 556, 635).

Figure 4 shows an example of AP recordings evoked with increasing current steps (from 5 to 15 pA) illustrating how CCs respond to constant depolarizations. Current injections induce trains of APs that gradually decrease in frequency (Figure 4A). The instantaneous firing frequency toward the end of the pulse (f_{ss}) is always smaller than one measured at the onset (f_o), giving rise to an adaptation ratio f_o/f_{ss} always >1 (Figure 4B). Increasing the injected current (from 5 to 15 pA), the CC responds with a marked increase of f_o (from 8 to 16 Hz) and f_{ss} that rises with the same proportion (from 2 to 4 Hz), indicative of the adapting behavior of these cells. The maximal f_o at very large depolarizations (15–20 pA) reaches values (16–18 Hz) that are comparable with those recorded in adrenal medulla slices (434) and with those induced by maximal sympathetic stimulation. The frequency of the adapted APs is significantly lower in mouse CCs (4–6 Hz) than in rat CCs (10–12 Hz) (178, 303, 689), most likely due to the different expression of BK channels in the two cell preparations (434). In all cases, the AP peak adapts steadily to a lower value, due to the incomplete recovery of Nav channels and BK channel activation induced by the constant (20 mV) cell depolarization.

AP firing adaptation is the result of an ionic equilibrium between ion channels carrying inward and outward currents. Figure 4C shows clearly that when SK channels are blocked with 100 nM apamin, the AP firing increases remarkably. The cell adapts more slowly to higher f_{ss}, and the AP amplitude falls even below overshoot (Figure 4B). Thus, the current-evoked AP firing is a potent tool to identify the key molecular components of CC excitability. Current-evoked AP firing has been successfully used to highlight the key roles of some ion channel and modulatory pathways in regulating CC excitability. Specifically, they have revealed: (i) the role of SK channels in setting firing frequency of mouse CCs (635), (ii) the dual action of leptin-mediated upregulation of BK channels through the activation of an IP3K pathway regulating spontaneous and evoked AP firing in mouse CCs (244), (iii) the BK channel inactivation regulating AP firing in rat CCs (581), (iv) the Cav1.3 channel regulation of AP firing in KO (635) and KI Cav1.3 in mouse CCs (556) and, (v) the existence of burst firing during sustained cell depolarization (434) and its block by nifedipine in mouse CCs (260).

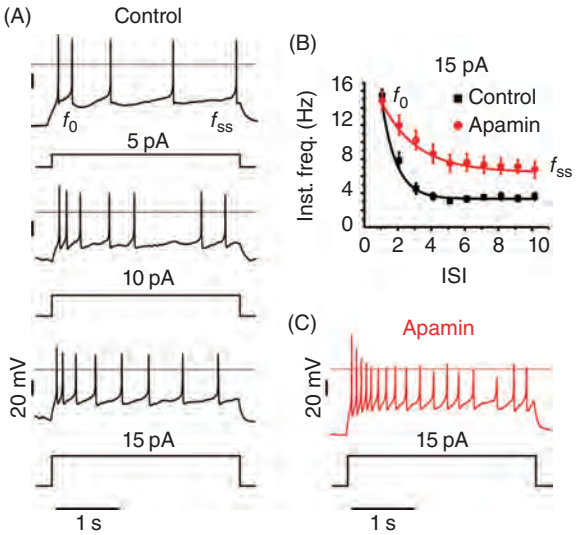

Figure 4 Spike frequency adaptation during current injections in mouse CCs. (A) Representative current-clamp recordings from WT mouse CCs in response to 5, 10, or 15 pA current injection from Vh = –70 mV (from top to bottom). (B) Evolution of the instantaneous firing frequency in WT mouse CCs at 15 pA in control (black squares) and in the presence of the SK channel blocker apamin (200 nM; red circles). (C) AP recordings in the presence of 200 nM apamin during 15 pA current injection, to be compared with the control trace to the left. Adapted, with permission, from Vandael DHF, et al., 2012 (635).

Action potentials elicited by splanchnic nerve stimulation and pulses of ACh

APs in CCs are generated by sympathetic splanchnic nerve stimulation that releases ACh and activates the nAChRs of the cells. Opening of nAChRs triggers excitatory postsynaptic potentials that initiate synchronous APs following splanchnic nerve stimulation. Alternatively, APs can be activated directly by brief pulses of ACh on cultured cells or adrenal gland slices (240). These two forms of stimulation are used sometimes for studying the modulatory effects of hormones, neurotransmitters, and drugs, which affect the stimulus-secretion coupling machinery in a cell system near physiological conditions (for a review, see Ref. 153). In the first case, recordings of APs are performed on the CCs of isolated bisected adrenal glands, which preserve their splanchnic innervation intact. CCs respond to low-frequency sympathetic stimulation (0.3, 1, and 3 Hz) with single APs that follow each stimulus synchronously, with no evidence of fatigue or desensitization (303). At higher frequencies (10 Hz), some stimuli fail to evoke a response. Failures of synaptic transmission are also observed in the superior cervical ganglion neurons during continuous stimulation at 10 and 20 Hz (58), suggesting strong similarities between the responses to splanchnic nerve stimulation of CCs *in situ* and sympathetic ganglion cells, and a weak linear correspondence between splanchnic stimulation and CC responses at a higher frequency. This approach has been used in the past to establish a correlation between the frequency of neuronal stimulation and the amount of released CA, with contrasting results on whether the two parameters

are linearly related or not in the range of physiological frequencies (0.3–30 Hz) (303, 658). Presently, this approach is not often used due to the complexity of the preparation and the technical difficulties to record stable APs, but it remains nevertheless a valuable tool to study stimulus-secretion coupling in intact innervated glands. A recent work, using a modified version of this technique, has shown remarkable spatial and activity-dependent differences in stimulus-secretion coupling between CCs releasing EPI and cells releasing NE (674).

APs induced by short puffs of ACh have been used recently for the purpose of mimicking the quantal release of ACh during single splanchnic nerve stimulation. de Diego et al. were first to design a protocol made of a train of brief pulses of 30 μM ACh lasting 25 ms of variable frequency (154) that mimicked the CC responses to trains of splanchnic nerve stimulations (153). In bovine CCs, the protocol could elicit trains of APs with similar waveforms to those recorded using either brief step depolarizations or single splanchnic nerve stimulations. All-or-none APs had a proper amplitude (65 mV from V_{rest}), half-width (2.7 ms), and well-resolved AHP (−17 mV from V_{rest}) indicative of the excellent state of excitability of the cells. Tonic firings with no sign of adaptation and failures could be achieved with frequencies ≤1 Hz. At higher frequencies (≥3 Hz), APs occurred irregularly and resting potential became unstable, most likely due to the incomplete fast washout of ACh after each brief application (153). Accumulation of ACh during repeated stimulation could induce nAChRs desensitization, activation of mAChRs, cell depolarization, and Nav channel inactivation. Thus, ACh-evoked APs appear to be a physiologically interesting way to induce cell firing in CCs, although the method requires technical improvements to study stimulus-secretion coupling mechanisms using AP frequencies above 3 Hz.

Nicotinic acetylcholine receptors of chromaffin cells

Stimulation of the sympathetic splanchnic nerve elicits the release of ACh from their nerve endings. ACh binds to nAChRs and mAChRs present in the CCs membrane. Membrane depolarization and AP firing were initially recorded in rat CCs upon activation of nAChRs (349). nAChRs play a central role in triggering fast CA secretion from adrenal CCs in response to ACh (175, 220). Pharmacological and immunological studies support the view that nAChRs expressed by CCs are of the neuronal type (142). nAChRs are formed by five subunits that span the membrane four times with the agonist-binding site located at the extracellular region, which is also structurally and functionally linked to the ion channel (152). Crystal structures of complete receptors reveal a cylinder-like structure made of five subunits symmetrically located around the ion channel. Single-channel nAChR conductance is ∼44 pS (221). The channel is permeable to Na^+, K^+, and Ca^{2+}, the latter contributing only 2% to 4% of the current (691).

The most conspicuous nAChR subtype involved in CA secretion is the heteromeric receptor formed by α3 and β4 subunits. In bovine CCs, two nAChR subtypes have been described. The main subtype is a heteromeric assembly of α3, β4, and possibly α5 subunits insensitive to α-bungarotoxin. The other subtype is α-bungarotoxin-sensitive homomeric α7 nAChRs (142). The transcription factor Sp1 (specificity protein 1) coordinates the synthesis of α3, β4, and α5 subunits that form the α-bungarotoxin-resistant nAChRs (57), while the transcription factor Egr-1 (early growth response protein 1) controls the differential expression of both α7 nAChR (114) and PNMT (185) in adrenergic CCs.

In addition to the typical nicotinic ligands, several unrelated substances of clinical relevance bound to nAChRs in CCs act as agonists, antagonists, or allosteric modulators. *Agonists* include ACh, carbachol, dimethylphenylpiperazinium, cytosine, and (+)-anatoxin-a that act on α3β4 receptors (142). Choline elicits $[Ca^{2+}]_c$ signals and secretion by acting on α7 receptors in bovine CCs (159, 232). A study on human CCs showed that the α7 nAChR-selective agonist PNU-282987 elicited whole-cell inward currents that were potentiated by allosteric α7 modulators 5-hydroxyindole and PNU-120596. Since α7 nAChR agonists choline and ONU-282987 augment secretion, it was concluded that human CCs express functional α7 nAChRs (508). In a similar study in bovine CCs, the authors conclude that CA release might be regulated by α7 and α3β47 nAChRs, depending on agonist concentrations and the presence of allosteric modulators of α7 nAChRs (159). The *antagonist* pharmacology of CCs nAChRs shows a classical "ganglionic" profile, with some additional blockers, like the spasmolytic otilonium (237), nanomolar concentrations of atropine (256), or the diuretic cyclothiazide (478). The involvement of α7 nAChRs in human CCs is supported by its partial blockade of CA secretion with α-bungarotoxin (405, 508). Some neuropeptides, that is catestatin, a fragment of CgA (294), substance P (132), and calcitonin gene-related peptide (CGRP) (164) also modulate the nAChRs of CCs.

In conclusion, although various subunits of nAChRs have been cloned and are expressed by CCs, the α3β4 is the predominant nAChR subtype in mediating the whole-cell nicotinic currents, $[Ca^{2+}]_c$ signaling, and the release of CA triggered by ACh in CCs. The α7 nAChR is also expressed by CCs, although its function is not yet fully characterized. A rich pharmacology is at hand either for activation or blockade of CC nAChRs, or to modulate them allosterically.

Ca^{2+} and Stimulus-Secretion Coupling

Ca^{2+} channel-secretion coupling

Ca^{2+} channel regulation by neurotransmitters: a historical background

Douglas and Rubin (172, 176) working in CCs and Katz and Miledi (337, 338) in presynaptic nerve terminals were the first to identify the role of Ca^{2+} influx as the key regulator of hormone and neurotransmitter release. Later studies uncovered the steep dependence of neurotransmitter release on Ca^{2+}

influx (169) and demonstrated the link between presynaptic Ca^{2+} currents and postsynaptic responses using the squid giant synapse (398). These results focused interest on Cav channels and their physiological role, with special emphasis on neurotransmitter and hormone release. It soon became evident that Cav channels are plastic and can be modulated by neurotransmitters, hormones, second messengers, and other intracellular chemicals, as well as by pharmacological agents. The first hormone-mediated pathway was described in cardiac cells where EPI or elevation of intracellular cyclic adenosine monophosphate (cAMP) facilitated Ca^{2+} channel activity (531, 621). The second neurotransmitter-mediated pathway was reported in chick sensory neurons where the addition of NE inhibited Ca^{2+} channel activity, the amplitude of Ca^{2+} currents, and the duration of APs (182, 183). In this section, we will describe a variety of mechanisms for the regulation of Cav channels of CCs by autocrine/paracrine neurotransmitters, hormones, and other modulators.

The role of Cav2.1 and Cav2.2 on excitation-secretion coupling in CCs

Cav2 channels (N, P/Q, and R) are highly expressed in the nervous system, where they carry the presynaptic Ca^{2+} currents that trigger neurotransmitter release and synaptic transmission (216, 530). Neurotransmitter release controlled by these voltage-gated channels is steeply Ca^{2+} dependent (third to fourth power) (169), making them an important locus of synaptic regulation. Among Cav2 channels, Cav2.1 and Cav2.2 are the main sources of the Ca^{2+} that initiates the rapid release of glutamate, ACh, and GABA from neurons. In addition, Cav2.1 and Cav2.2 contain a synprint region that binds to syntaxin 1A and SNAP-25 (115), suggesting that they colocalize to regions of the membrane where the SNARE complex is formed and synaptic vesicle fusion occurs to initiate neurotransmitter release. Cav2 channel activation is also critically regulated by several G-protein subunits (686), which form the basis of Ca^{2+}- and voltage-dependent signal transduction at the synaptic terminal (116).

In CCs, Cav2.1 and Cav2.2 are highly expressed, but at different densities, in all animal species (240). The two channels are effectively coupled to secretion, with Ca^{2+} dependence of secretion not as steep as in presynaptic terminals. The dependence on Ca^{2+} is nearly linear and comparable to that seen with the other Ca^{2+} channels expressed in CCs (L, R, and T types) (100, 103, 248, 308, 352, 543, 609). This means that Cav2 channel opening is loosely coupled to readily releasable secretory vesicles, which is consistent with the idea that Ca^{2+} channels and release sites in CCs are not closely colocalized as in presynaptic neuronal terminals (130). Ca^{2+} channels and release sites are distributed within nanometric distances (200–300 nm) to form specialized membrane regions with dimensions of several micrometers (357, 469). In this way, the dominant Ca^{2+} signal regulating vesicle fusion and neurotransmitter release derives from the activation of several Cav channel subtypes distributed over areas covering tens of square micrometers, rather than from dense Ca^{2+} channel clusters localized near some readily releasable vesicles at the presynaptic secretion sites similar to the active zones (469, 470).

Regarding the regulatory role of Cav2.1 and Cav2.2 channels in secretion, most electrophysiological studies support the idea that both channels are equally accessible to the secretory apparatus, without any preferential coupling (30, 100, 206, 230, 352). Nonetheless, using Cav2.1 KO mice, a predominant role of P/Q-type channels in regulating the fast release of vesicles from the immediately releasable pool (IRP; see below for an accurate definition) has been proposed (20). Using short square pulses (10 ms) to 0 mV from −80 mV to specifically recruit vesicles from the IRP, it was shown that Cav2.1 channels control most of the IRP. Finally, it is worth noticing that depending on the activation gating of Cav2 channels, it is likely than Cav2.1 channels exert a key role in secretion when using trains of triangular APs rather than square pulses (122). This is likely associated with the fast activation of Cav2.1 with respect to the other Cav channels, which is more evident with short stimuli since less affected by the fast Ca^{2+}-dependent inactivation (CDI) of the channel. This suggests that channel activation and the type of stimuli applied, rather than the specific colocalization of the secretory apparatus with Ca^{2+} channels, critically regulate exocytosis in CCs.

The voltage-dependent modulation of Cav2.1 and Cav2.2 by neurotransmitters: physiological significance

As shown in the previous section, due to their higher threshold of activation, Cav2 channels contribute mainly to the upstroke and falling phase of APs, while Cav1 channels (Cav1.2 and Cav1.3) control the subthreshold current regulating AP firing in rat and mouse CCs (426, 429). Cav2 channels are also uniquely modulated in a voltage-dependent manner by G-protein-coupled receptor (GPCR) pathways (314). In CCs, Cav2.1 and Cav2.2 are autocrinally inhibited by ATP and opioids that are released together with CAs during cell activity (8, 10, 149, 235). The inhibition occurs in membrane microdomains, without the involvement of diffusible second messengers, and is manifested by a delay of channel openings (slow activation) at low potentials (Figures 5A and 5B) (98, 102). This effect, however, can be reversed by depolarizing voltage steps. The normal fast activation is recovered during strong depolarizations to +100 mV (52, 430) or when a strong depolarizing prepulse anticipates a test depolarization to 0 mV (Figures 5A-5C) (201). This phenomenon is called "voltage-dependent facilitation" and is attributed to a protein-protein interaction between the activated GPCR βγ subunit and several sites on both the Cav2 α1 subunits: the N-terminus, the I–II linker domain, and probably the C-terminus (see Ref. 686 for a recent review). Remarkably, this inhibition of Cav2.1 and Cav2.2 can be partially recovered during brief depolarizations repeated at high frequency (150) as it occurs during high-frequency AP

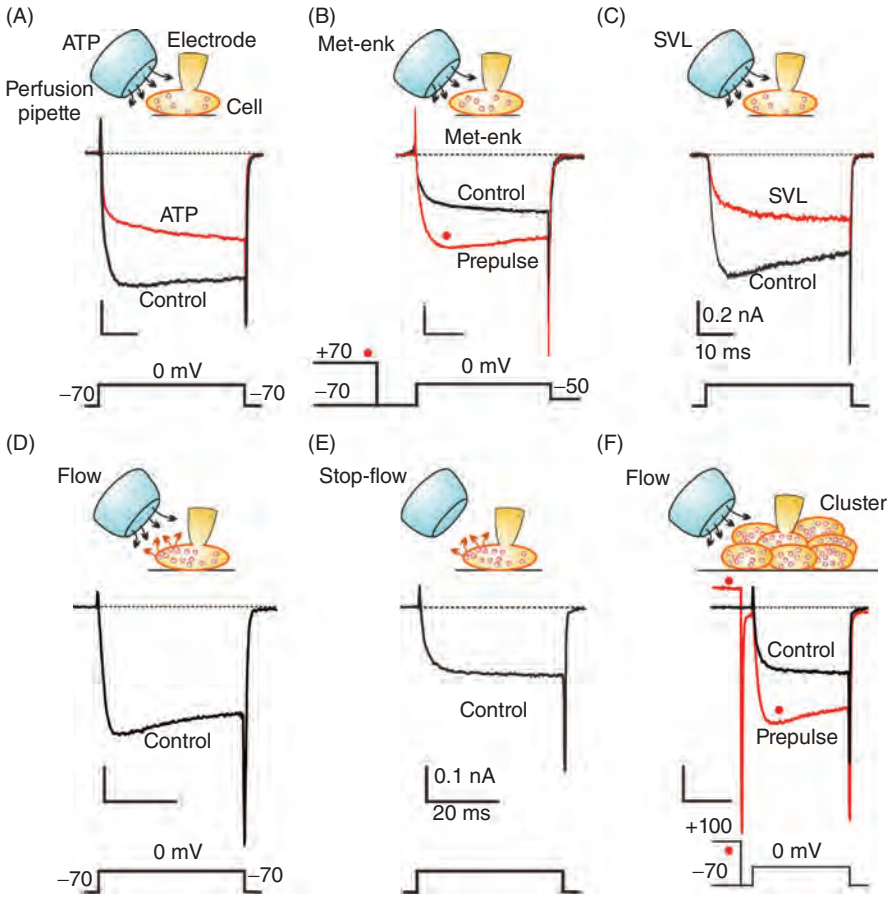

Figure 5 Voltage-dependent modulation of $Ca_V2.1$ and $Ca_V2.2$ in CCs. (A) Acute application of ATP (50 μM) slows down the activation of N- and P/Q-type Ba^{2+} currents recorded at 0 mV in a bovine CC (for details, see Ref. 98). (B) The delayed activation of N- and P/Q-type Ba^{2+} currents induced by the acute application of met-enkephalin (10 μM; black trace; control) is recovered by a 50-ms prepulse step depolarization to +70 mV (red dot; red trace) (for details, see Ref. 573). (C) Acute application of the soluble vesicle lysate (SVL) containing (EPI, NE, opioids, and ATP) causes N- and P/Q-type current delayed activation in bovine CCs (for details, see Ref. 10). (D, E) Autocrine inhibition of N- and P/Q-type channels revealed by changing cell superfusion from "stop-flow" to "flow" condition, in bovine CCs. In the "flow" condition, there is no autocrine inhibition. Ba^{2+} currents at 0 mV are fast activating. In the "stop-flow" condition, the autocrine-released material inhibits through GPCRs the opening of Ca_V2 (N- and P/Q-type) channels, inducing marked activation delay. Adapted, with permission, from Carabelli V, et al., 1998 (98). (F) Ba^{2+} currents recorded from a cell that is part of a cluster undergo robust autocrine modulation (black trace, control). A prepulse to +100 mV is able to rescue the fast channel activation by removing the autocrine inhibition induced by the neurotransmitters released by the surrounding cells (for details, see Ref. 290).

trains occurring during stress-mimicking conditions. The result is that the reduced Ca^{2+} entry through $Ca_V2.1$ and $Ca_V2.2$ at rest, due to the downregulation induced by the released opioids and ATP, can be partially recovered during sustained cell activity. This "autocrine inhibition" of Ca_V2 channels was first discovered by applying the purified low molecular weight components of secretory vesicles (soluble vesicle lysate, SVL), containing EPI, NE, opioids, and ATP, directly onto bovine CCs (Figure 5C) (10). Application of SVL caused the typical slowdown of Ca_V currents induced by applied neurotransmitters that could be removed by strong pre-step depolarizations. This report also showed that the same autocrine inhibition occurs by stopping the flow of external solution perfusing the cell (*stop-flow*), allowing the unwashed released neurotransmitters (ATP and opioids) to activate the inhibitory GPCR pathway that slows down Ca_V2 currents (Figure 5E). This resting autocrine inhibition of Ca_V2 channels is particularly evident in clusters of bovine CCs (290) (Figure 5F) and in mouse adrenal gland slices (292). In these tissue preparations, the packed organization of the cells is well preserved and the released neurotransmitters can accumulate in the extracellular space to exert a basal tonic inhibition on cell firing and CA secretion that is facilitated by prepulse depolarizations. The application of opioids or ATP

directly on bovine CCs mimics the effects of SLV application (Figures 5C and 5F).

The effective action of this autocrine modulation derives from the high concentration of neurotransmitters stored in the CC granules (0.8–1 M CA, ~200 mM ATP, and 1–2 mM met-enk; see below) and the high density of adrenergic (α_2-AR, β_1-AR, and β_2-AR) (78, 121, 355), opioidergic (μ and δ) (8, 355, 624), and purinergic (P_{2y}) receptors (98, 149, 519, 627) expressed in bovine, rat, and mouse CCs. It is noteworthy that rat CCs also possess ligand-gated purinergic receptors (P_{2X3} and P_{2X7}), which are upregulated during pain-induced stress in chronic pain rat models (28). This suggests a key role of P_{2Y} and P_{2X} receptors in regulating cell depolarization, AP firing, and CA release. The role of secreted ATP modulating the quantum characteristics of CA exocytosis through purinergic receptor activation has also been recently demonstrated (421).

In conclusion, it seems that the autocrine inhibition of the Ca_V2 channel acts primarily as negative feedback to regulate the amount of secretion. With increased firing rates, the autocrine inhibition may still act to prevent excessive CA release, but when under intense APs stimulation, a large surge of CAs is required. CCs are able to overcome the inhibition by facilitating Ca_V2 currents in an activity-dependent manner.

The voltage-independent modulation of $Ca_V2.1$ and $Ca_V2.2$ by neurotransmitters

Voltage-independent inhibition of Ca_V2 channels also exists and likely includes several distinct modulatory mechanisms. In CCs, the neuronal Ca^{2+} sensor-1 (NCS-1) exerts a tonic voltage-independent inhibition of $Ca_V2.1$ channels (665). NCS-1 acts through an autocrine, purinergic, and opioidergic receptor-mediated pathway and the activation of PTX-insensitive G-proteins. To complete the $Ca_V2.1$ channel inhibition in CCs, it is also necessary that the $Ca_V2.1$ α1-subunit be phosphorylated at the tyrosine residues by a Src-like kinase, strictly controlling Ca^{2+}-dependent exocytosis through a series of biochemical steps (665). Specifically, NCS-1 is shown to regulate CC secretion by favoring PIP_2 production, leading to $InsP_3$ increases and Ca^{2+} release from intracellular stores (500). A similar voltage-independent inhibition of $Ca_V2.1$ and $Ca_V2.2$ channels mediated by PIP_2 and PKC has been reported in the sympathetic superior cervical ganglion and transfected TsA201 cells (596). Voltage-independent inhibition of Ca_V2 channels is also produced by Gq-coupled H1-histamine receptors in bovine CCs (151).

Modulation of $Ca_V2.1$ and $Ca_V1.3$ channels in CCs: a role in stimulus-secretion coupling

The important participation of L-type channels in the Ca^{2+}-dependent release of CAs from the adrenal medulla was first reported in a pioneering set of experiments (243). Subsequent reports confirmed this observation and showed that due to their slow inactivation, Ca_V1 are the Ca^{2+} channels mostly contributing to CA secretion when long-lasting stimuli are applied. Sustained depolarization with high KCl solutions (404), prolonged applications of ACh (325, 461), or repeated splanchnic nerve stimulation (6) in isolated cells or intact adrenal glands of various animal species revealed a predominant L-type channel regulation of CA release (see Refs. 70, 240, 417, 463, 634 for recent reviews). This slow action occurs independently of the expression densities of Ca_V1 channels and it is associated with the unique gating properties of these channels. Two features, in particular, are the slow Ca^{2+}-dependent inactivation that allows sustained Ca^{2+} fluxes during prolonged (or repeated) depolarizations and the weak steady-state inactivation of both channels at −50 and −60 mV, the latter favoring channel availability near the resting membrane potentials. When exocytosis is evaluated using capacitance changes on single isolated cells, the L-type Ca^{2+} current possesses the same Ca^{2+} sensitivity of Ca_V2 and Ca_V3 channels and contributes proportionally to their density of expression (100, 103, 206).

The voltage-independent direct and remote autocrine modulation of L-type channels

The Ca_V1 (L-type) channels, like the Ca_V2 type, experience basal and stimulus-induced autocrine modulation, which affects the amount of Ca^{2+} entry that regulates CA secretion. This autocrine effect is mediated by a variety of GPCRs, including adrenergic, opioidergic, and purinergic, expressed in CCs. It occurs in isolated CCs (Figures 5A-5C) (10, 121, 288, 419) but is more prominent in cell clusters (236) and in adrenal gland slices (292), in which, as *in vivo*, released neurotransmitters accumulate between closely packed CCs (Figure 5F).

The autocrine modulation of L-type channels in CCs is mainly voltage independent and occurs through two opposing distinct pathways (see Refs. 109 and 417 for a review): (i) rapid inhibition of Ca_V1 channel gating via PTX-sensitive G-proteins (*direct inhibition*) or (ii) slow upregulation of Ca_V1 channel activity through a cAMP/PKA-mediated phosphorylation (*remote upregulation*), similar to the upregulation of cardiac $Ca_V1.2$ channels under β1-AR-mediated sympathetic stimulation. The *direct inhibition* is fully apparent in membrane microdomains where Ca_V1 channels and GPCRs interact to reduce the open channel probability and Ca^{2+} entry (98, 101, 288, 292). The *remote upregulation* requires the presence of β-adrenoceptors (β-ARs), functional adenylate cyclases, PKA, and Ca_V1 channels and occurs in nearly all the CCs of all animal species including humans (101, 121, 138, 229, 428); for a review, see Refs. 46, 109, 417, 426, 427, and 634.

L-type channels are also regulated by a remote mechanism, in addition to neurotransmitter-mediated modulation, involving the NO/cGMP/PKG pathway which tonically inhibits Ca_V1 channels and CA release in bovine (99, 561) and mouse CCs (419). The NO/cGMP/PKG-mediated downregulation of L-type channels and cAMP/PKA-mediated upregulation act oppositely, just as they act on cardiac $Ca_V1.2$ channels. An interesting question is whether $Ca_V1.2$ and $Ca_V1.3$,

which are equally expressed in both mouse and rat CCs, are both modulated by NO/cGMP/PKG- and cAMP/PKA-driven mechanisms. Using $Ca_V1.3^{-/-}$ KO mice, it was demonstrated that both channels are equally up- or downregulated by the two opposing pathways (419). The two pathways act independently on the two channels and may induce almost an order of magnitude variation of L-type current amplitudes when concomitantly regulated. Figure 6 illustrates the cascade of events of the two opposing modulatory pathways. The upper part shows cAMP/PKA-mediated upregulation driven by the autocrine activation of β-ARs. The lower part shows the NO/cGMP/PKG-mediated downregulation driven by different stimuli. Figure 7 summarizes the two main experiments that showed how Ca_V1 currents in WT mouse CCs can be upregulated by inhibiting the NO/cGMP/PKG cascade and activating the cAMP/PKA pathway (bottom part) or drastically downmodulated by inhibiting cAMP/PKA pathway and stimulating the NO/cGMP/PKG cascade (top part) (see Figure 7 legend for further details).

Concerning the functional relevance of this dual modulation of $Ca_V1.2$ and $Ca_V1.3$ L-type channels, we point out that cAMP/PKA and cGMP/PKC are likely active even at rest due to the basal activity of the two kinases. PKA can be stimulated by PACAP (526), Ca^{2+} entry, and G-protein subunits that are activated by the basal activity of first messengers released from sympathetic neurons (24), surrounding capillaries (431, 670), and by the autocrine activity of CCs (10, 121). The soluble GC is activated by the resting NO levels generated by the Ca^{2+}-calmodulin-mediated activation of NO synthase (NOS) expressed in most CCs (494, 561). Under these conditions, cGMP/PKG appears to work as a "brake" to limit the potentiating effects of cAMP/PKA and helps set the resting levels of $Ca_V1.2$ and $Ca_V1.3$ currents, which regulate the resting potential and basal repetitive firing.

A *synergistic potentiation* of Ca_V1 channels could occur during sustained splanchnic nerve stimulation that releases PACAP (*vide infra*) and induces a massive release of EPI from CCs, which would further elevate the levels of cAMP/PKA

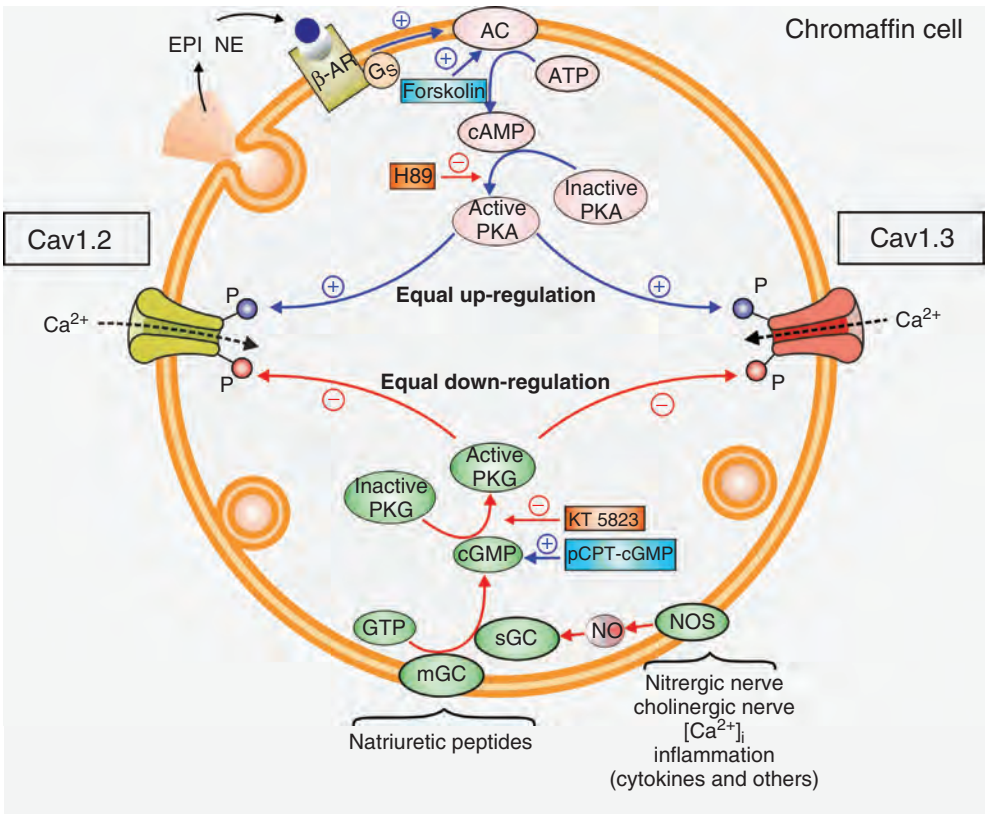

Figure 6 Up- and downmodulation of $Ca_V1.2$ and $Ca_V1.3$ channels by the cAMP/PKA and NO/cGMP/PKG pathways in mouse CCs. The top half illustrates the molecular components and the sequential steps of the β-AR-mediated upregulation of $Ca_V1.2$ and $Ca_V1.3$ L-type channels through the activation of adenylate cyclase (AC), leading to cAMP production, activation of PKA, and Ca_V1 channel phosphorylation, causing an increase in open channel probability. The bottom part shows the molecular components and the sequential steps of the NO-mediated downregulation of $Ca_V1.2$ and $Ca_V1.3$ L-type channels through the activation of a soluble guanylate cyclase (sGC), leading to cGMP production, activation of PKG, and Ca_V1 channels phosphorylation, causing a decrease in open channel probability. NO is produced by membrane NO-synthases. cGMP is also produced by a membrane guanylate cyclase (mGC). Adapted, with permission, from Mahapatra S, et al., 2012 (417).

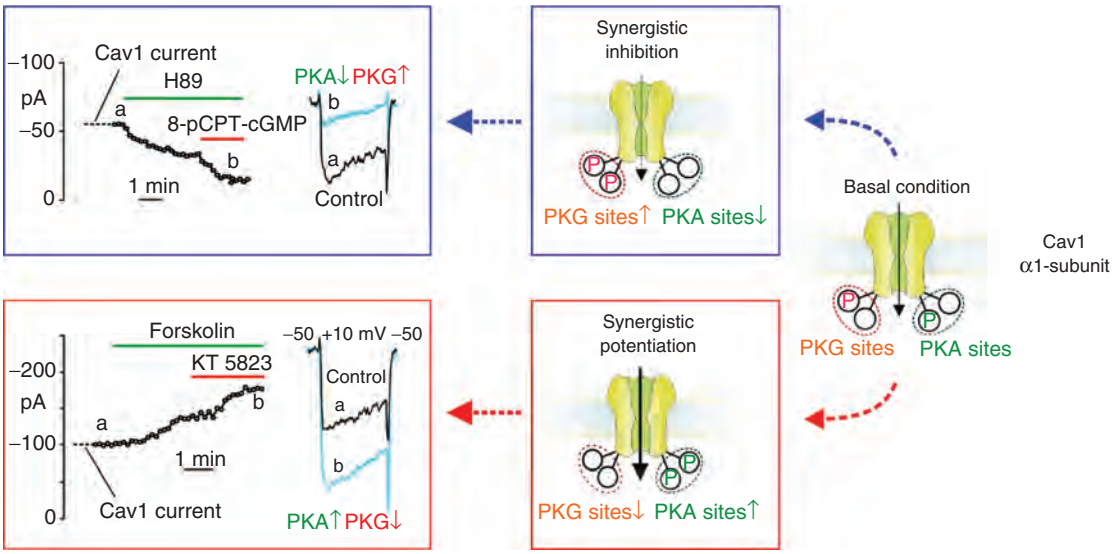

Figure 7 Synergistic effects of cAMP/PKA and cGMP/PKG pathways on Cav1 currents of WT mouse CCs. The right side is a schematic representation of Ca_V1 channel α1 subunit with two hypothetical PKA and PKG phosphorylation sites (P). The schemes represent the situation under basal conditions (middle), a synergistic potentiation (top), and a synergistic inhibition (bottom) of Ca_V1 channel. PKA and PKG P-sites are partially phosphorylated (P) or unphosphorylated under resting conditions. Phosphorylation and dephosphorylation drove by up- and downregulation of PKA and PKG proceed independently of each other and can reach two extreme conditions. In one case, the two PKA P-sites are dephosphorylated and the two PKG P-sites are phosphorylated (minimal Ca_V1 current; cyan trace, on the top left panel). Alternatively, the PKA sites are phosphorylated and PKG P-sites are dephosphorylated (maximal Ca_V1 current; cyan trace, on the bottom left panel). The two panels to the left show the time course of synergistic downregulation of Ca_V1 channels induced by the sequential application of the PKA inhibitor H-89 and the PKG activator 8-pCPT-cGMP (top) and the synergistic upregulation of Ca_V1 channels by sequential application of the PKA activator forskolin and PKG inhibitor KT 5823 (bottom). Adapted, with permission, from Mahapatra S, et al., 2012 (417); Adapted, with permission, from Vandael DHF, et al., 2013 (634) (drawing and experimental data).

through the autocrine activation of the β_1-ARs (121, 428). The increased Ca^{2+} entry could, in turn, upregulate PDE1, the cGMP-hydrolyzing and Ca^{2+}-calmodulin-activated PDE that controls the resting levels of cGMP (561, 637). Activation of a cGMP-specific PDE that lowers cGMP, inhibiting PKG, and the parallel activation of PKA during PACAP release and β_1-AR stimulation could markedly boost the L-type Ca_V1 currents. This regulation would overall serve to sustain the rapid increase of cell firing activity and CA release during the "fight-or-flight" response to stressors in CCs. On the other hand, a *synergistic inhibition* could occur if, as in mammalian ventricular myocytes, CCs possess cGMP-activated PDE2 isoforms that hydrolyze cAMP (410). Any robust upregulation of the NO/cGMP/PKG pathway under these conditions would enhance cGMP and downregulate cAMP, rapidly depressing $Ca_V1.2$ and $Ca_V1.3$ channel gating. The existence of various PDEs acting on cAMP in CCs is supported by the observation, in mouse CCs, that the nonspecific PDE blocker IBMX increases basal cAMP levels more potently than the PDE-4-specific blocker rolipram (428).

Regulation of endocytosis by L-type Ca^{2+} channels

To ensure that the size of nerve terminals and neuroendocrine cells is preserved during cell activity, excess vesicle membrane incorporation into the cytosolic membrane during exocytosis must be compensated by an equivalent membrane retrieval during subsequent endocytosis (see the following section). This mechanism ensures that a given number of vesicles are available to replenish the secretory vesicle pool and participate in subsequent rounds of exocytosis during repetitive cell activation (33, 118, 284). Like exocytosis, endocytosis is a Ca^{2+}-dependent process in CCs (33, 481). The question is whether some Ca_V channels (Ca_V1 and Ca_V2) are preferentially coupled to endocytosis or not.

In bovine CCs stimulated with long depolarizing pulses, there is a preferential coupling of L-type Ca_V1 channels to endocytosis (541). In spite of the small contribution of Ca_V1 channels to the whole-cell Ca^{2+} current, this shows that nifedipine abolishes the endocytotic response, without significantly affecting exocytosis that is also sustained by $Ca_V2.1$ and $Ca_V2.2$ channels. In the presence of FPLA64176 (an L-type Ca_V channel agonist), the increased Ca^{2+} entry doubles the endo/exocytosis ratio, indicating a selective augmentation of endocytosis associated with the selective Ca^{2+} entry increase through Ca_V1 channels (543). In mouse CCs, the membrane excess retrieval following strong Ca^{2+} entry is suppressed by nitrendipine, suggesting the direct involvement of Ca_V1 channels (511).

Immunofluorescence experiments on bovine CCs have shown negligible colocalization of clathrin and dynamin to

L-type Ca^{2+}-channels (543). This, and the additional studies in CCs (136), support the idea that a low-rate, non-inactivating Ca^{2+}-entry through Ca_V1 channels ($Ca_V1.3$) might be more critical to trigger compensatory as well as excess exocytosis. These data also support the idea that not all Ca^{2+} that enters CCs during depolarization through slow-inactivating Ca_V1 channels or through fast-inactivating $Ca_V2.1$ and $Ca_V2.2$ channels has the same physiological function (463).

Ca^{2+} handling by CCs: impact on exocytosis

That Ca^{2+} is the coupling agent in the stimulation-secretion process was established in pioneering experiments in perfused cat adrenal glands: ACh stimulation triggered a Ca^{2+}-dependent CA release (176) that was associated with enhanced Ca^{2+} entry via Ca_V channels (174). Since then, we have learned much more about the complexities of enhanced Ca^{2+} entry and secretion. The details of the stimulus-secretion coupling process (172) have been amply clarified using Ca^{2+}-sensitive probes, particularly aequorins targeted to different organelles (537) as well as patch-clamp (271) and amperometric techniques (668) to measure the exocytotic release of CAs with high temporal resolution.

Several ion channels and transporters tightly regulate Ca^{2+} handling in excitable cells. This exquisite control of the cycling of Ca^{2+} is vital to cell function and survival. Concerning CCs, we will review the cycle of Ca^{2+} that comprises four processes: Ca^{2+} entry, Ca^{2+} efflux, Ca^{2+} redistribution into organelles, and Ca^{2+} release from those organelles.

Ca^{2+} entry

Ca^{2+} entry through the various Ca_V channels is the primary determinant in shaping the $[Ca^{2+}]_c$ elevations occurring during CC activation. Although Ca^{2+} entry through the plasmalemma is mainly associated with Ca_V channels, Ca^{2+} can reach the cytosol through the nAChRs as well as the store-operated Ca^{2+} channels (SOCCs). The characteristics and functions of Ca_V channel subtypes and their role in the regulation of CA release have been described earlier (*Ca^{2+} channel-secretion coupling*). Those of nAChR and SOCC channels in Ca^{2+}-handling and transport have been discussed in detail elsewhere (242).

Ca^{2+} efflux

There are two plasmalemma transporters for pumping Ca^{2+} out of the CCs. These are the plasma membrane Ca^{2+}-ATPase or Ca^{2+} pump (PMCA) and the Na^+/Ca^{2+} exchanger (NCX). The Ca^{2+} pump, inhibited by vanadate and lanthanum, has a high affinity for Ca^{2+} (submicromolar K_D) and transports one Ca^{2+} ion for each ATP hydrolyzed (79). The H^+/Ca^{2+} transport ratio for PMCA in reconstituted *in vitro* systems has been estimated at 1:1 (165), and therefore PMCA pumping would be electrogenic (551) and sensitive to membrane potential. Nevertheless, in neurons, PMCA exchanges two H^+ for each Ca^{2+} ion extruded, that is it is electroneutral (612). PMCA is modulated by numerous factors, but mainly calmodulin. When intracellular Ca^{2+} increases, calmodulin binds to PMCAs, increasing their Ca^{2+} affinity. The PMCAs are encoded by four different genes: PMCA1 and PMCA4, which are ubiquitously expressed, and PMCA2 and PMCA3, expressed predominantly in the CNS (106). The Na^+/Ca^{2+} exchanger uses the energy of the Na^+ gradient, to exchange three external Na^+ ions for one internal Ca^{2+} ion (42); its function is, therefore, electrogenic. The exchanger can also work in the "reverse mode," moving Na^+ out of the cell and Ca^{2+} into the cell; this occurs during membrane depolarization and/or when intracellular Na^+ concentration increases, for instance after intense AP firing (63).

Using plasma membrane purified from bovine adrenal medullae, a first functional characterization of the two transporters was achieved (335). Later, it was found that bovine CCs express NCX1, the major isoform of the exchanger (497). NCX1 can adopt two functional modes: the forward mode that favors Ca^{2+} efflux (520) and the reverse mode that favors Na^+-dependent Ca^{2+} influx (391). Changes in the Na^+ gradient, either directly through manipulation of ion concentrations (499, 501, 536) or indirectly through inhibition of the Na^+ pump with ouabain (213, 241), augment Ca^{2+} entry and the release of CAs. This has suggested a role of the NCX in the regulation of Ca^{2+} signaling and exocytosis in CCs. However, an alternative explanation in the case of experiments with ouabain involves its ability to release Ca^{2+} from the ER (443).

Ca^{2+} sequestration

The membrane of the ER and sarcoplasmic reticulum (SR) contains a Ca^{2+} pump, the sarcoendoplasmic reticulum Ca^{2+}-dependent ATPase (SERCA), of which there are three major isoforms (SERCA1–3). SERCA1a-b and SERCA2a are present in skeletal and cardiac muscles, while SERCA2b is expressed in all nonmuscle tissues including nerve cells. SERCA keeps intracellular Ca^{2+} concentration low and Ca^{2+} concentration high inside the ER/SR, creating the conditions for cytosolic Ca^{2+} transients and oscillations in response to a variety of external stimuli that allow ER Ca^{2+} release. Phospholamban (PLB), a small protein expressed in muscle and integral to the ER/SR membrane, when nonphosphorylated, binds to SERCA and decreases its affinity for Ca^{2+}, and when phosphorylated, it detaches from the pump, relieving the inhibition. The activity of all SERCA isoforms is specifically inhibited by thapsigargin with half-maximal inhibitory potency of 10 to 20 nM (106).

Redistribution of Ca^{2+} into, and release of Ca^{2+} from, the endoplasmic reticulum

Several laboratories have approached the study of Ca^{2+} circulation in and out of the cytoplasm and ER Ca^{2+} store of CCs. Upon cell activation, increased cytoplasmic Ca^{2+} concentration ($[Ca^{2+}]_c$) activates Ca^{2+} uptake into the ER lumen

through the SERCA. For instance, upon stimulation of bovine CCs (17, 640, 678) or rat CCs (295), Ca^{2+} is effectively taken up by the ER, to reach concentrations as high as half millimolar within the ER lumen (17).

Various stimuli are known to release Ca^{2+} from the ER through two channels, namely, the inositol tris-phosphate receptor ($InsP_3R$) and the ryanodine receptor (RyR). Carbachol, histamine, bradykinin, and angiotensin II augment the synthesis of $InsP_3$ in bovine CCs (477, 518, 553) in parallel with $[Ca^{2+}]_c$ increase (589). These ER Ca^{2+}-mobilizing actions are mimicked by direct stimulation with $InsP_3$, suggesting that they are mediated by the plasmalemmal receptors for these first messengers to generate $InsP_3$ that will finally elicit Ca^{2+} release via $InsP_3Rs$ (589, 590).

The functional correlation of the $InsP_3$ ER Ca^{2+} release pathway has been studied in more detail with agonists for metabotropic receptors. Thus, stimulation of bovine CCs with histamine (29) or guinea-pig CCs with muscarine (487) augments $[Ca^{2+}]_c$ to elicit the activation of Ca^{2+}-dependent SK and BK channels that gives rise to cell hyperpolarization. In line with this is the observation that SK and BK channels regulate the nicotinic and muscarinic secretory responses of cat and bovine CCs (371, 625, 626). A short application of histamine causes a transient mild secretory response (83), while a longer application causes a greater effect (83, 397, 476). Most likely, the histamine-elicited $[Ca^{2+}]_c$ elevation has two components: an initial transient phase linked to ER Ca^{2+} release and a late, sustained phase due to Ca^{2+} entry (485, 589, 590, 687); but see (64). The second component has been linked to the inhibition of a K_V7 (M-current) potassium channel with an associated depolarization and augmented Ca^{2+} entry through open Ca_V channels (660). Angiotensin II also increases cytosolic Ca^{2+} and stimulates exocytosis in bovine CCs, but to a lesser extent than histamine (126, 590).

The second pathway for Ca^{2+} release from the ER is the RyR Ca^{2+}-release channel. An activator of this channel, caffeine, causes rapid Ca^{2+} release in bovine CCs (126). Caffeine effects displayed a "quantal" pattern as if Ca^{2+} release from the ER occurred in steps; thus, it was concluded that the caffeine-sensitive Ca^{2+} pool is composed of different functionally discrete stores (124, 126, 127). The presence of separate or overlapping Ca^{2+} stores sensitive to histamine or caffeine and their functional significance have been under debate since the 1990s (123, 392, 538, 589).

How the $InsP_3$-sensitive and the caffeine-sensitive Ca^{2+} stores interact was partly clarified in bovine CCs transfected with ER-targeted aequorin (17, 640). These experiments suggest that in CCs, the ER behaves as a single thapsigargin-sensitive Ca^{2+} pool that releases Ca^{2+} through a Ca^{2+}-induced Ca^{2+} release (CICR) mechanism mediated by RyR or $InsP_3Rs$. Later reports suggested that in mouse CCs in the intact adrenal gland, CICR is either small or nonexistent (535), but in another study in cultured mouse CCs, a functional CICR mechanism was found (675). The contribution of the ER Ca^{2+} store to the regulation of exocytosis has been studied by several laboratories. In voltage-clamped bovine CCs, depletion of the ER Ca^{2+} store with a SERCA blocker either did not affect exocytosis (451) or depressed it (498). In a third study also in bovine CCs, ER Ca^{2+} depletion depressed the ACh secretory responses but not that triggered by depolarizing high-K^+ solution. This difference was explained assuming that ACh produces discrete and more localized $[Ca^{2+}]_c$ transients at sub-plasmalemmal regions, while high K^+ elicits greater $[Ca^{2+}]_c$ transients that spread quickly throughout the cytosol (145). Nevertheless, sustained stimulation of bovine CCs with caffeine caused ER Ca^{2+} depletion and a decrease of the K^+-elicited secretory responses. It seems, therefore, that depending on its grade of filling, the ER may behave as a Ca^{2+} sink when empty, or to augment $[Ca^{2+}]_c$ signals and exocytosis by a CICR mechanism when full (370).

The ER Ca^{2+} store could also have a regulatory function on Ca^{2+}-dependent pre-exocytotic steps, that is promoting the flow of secretory vesicles from a reserve pool (RP) toward the sub-plasmalemmal readily release vesicle pool. This is supported by experiments in voltage-clamped bovine CCs that use histamine to elicit mild $[Ca^{2+}]_c$ elevations elicited by ER Ca^{2+} release; although these $[Ca^{2+}]_c$ elevations were subthreshold for exocytosis, they caused a clear augmentation of the exocytotic response elicited by depolarizing pulses (652).

Redistribution of Ca^{2+} into, and release of Ca^{2+} from, mitochondria

Mitochondria use the driving force of the large electrical potential across their membrane (nearly −180 mV) to import vast amounts of Ca^{2+} through their Ca^{2+} uniporter (532). Mitochondria behave as a temporary Ca^{2+} store and export Ca^{2+} back into the cytosol by exchanging one Ca^{2+} for 2 Na^+ ions via the mitochondrial electroneutral Na^+/Ca^{2+} exchanger (mNCX). A less-active H^+/Ca^{2+} exchanger has also been described (105, 264). As the uniporter has a low affinity for Ca^{2+}, mitochondria take up large quantities of this cation efficiently only when overall intracellular Ca^{2+} concentrations are high, or if mitochondria are close to cytosolic high Ca^{2+} microdomains (HCMDs) that build-up upon Ca^{2+} entry through Ca_V channels at sub-plasmalemmal sites (640). This also occurs with HCMDs close to $InsP_3$ receptors that are sensed by neighboring mitochondria (537).

During stimulation, mitochondria of rat CCs behave as rapid and reversible Ca^{2+} buffers (40, 504). However, the use of Ca^{2+} probes in these experiments to monitor Ca^{2+} concentrations in the mitochondrial matrix ($[Ca^{2+}]_m$) revealed increases only in the low micromolar range (40). This is likely due to an underestimation due to the saturation of the Ca^{2+} probe. In bovine CCs, mitochondria also contribute to the clearance of large cytosolic Ca^{2+} loads (640, 678). Mitochondria-targeted aequorins with different Ca^{2+} affinities in bovine CCs revealed surprisingly rapid $[Ca^{2+}]_m$ transients, nearly in the millimolar range upon stimulation with ACh, caffeine, or high K^+ (453).

The impact on exocytosis of such avid mitochondrial Ca^{2+} uptake has been explored in several laboratories. For instance, dissipation of the proton gradient by protonophores, which drastically decreases the Ca^{2+} buffering capacity of mitochondria (453, 682), results in a pronounced augmentation of the exocytotic responses (452, 453). Such potentiated secretion has also been observed in fast-perifused bovine CCs stimulated with ACh, caffeine, or K^+ (112, 144, 145, 453), as well as in embryonic and adult rat CCs (636) and in mouse CCs after pharmacological interfering with the mitochondrial Ca^{2+} uniporter (MICU) and the mNCX (402). The inhibition of the Ca^{2+} uniporter also augments the secretory response of bovine CCs (682). However, in mouse CCs, the protonophores depressed the K^+-evoked $[Ca^{2+}]_c$ signals and the secretory responses (112). This could be due to a different expression of Ca_V channel subtypes and different inactivation rates during the blockade of mitochondrial Ca^{2+} sequestration by the protonophores (291).

An integrative view of Ca^{2+} handling by CCs

The rates of Ca^{2+} entry, its redistribution into CC organelles, its release back to the cytosol, and its extrusion to the extracellular space have been calculated with both direct and indirect approaches (640). Ca^{2+} entry into CCs through the various Ca_V channel subtypes is the primary determinant of the initial $[Ca^{2+}]_c$ transient. Thus, for a 15-µm diameter bovine CC, the rate of Ca^{2+} entry can be calculated from the measured Ca^{2+} inward current (692) or from the rate of $^{45}Ca^{2+}$ uptake into K^+ depolarized cells (32). The mean rate of Ca^{2+} entry from the two sets of experiments is around 500 µmol L cell^{-1} s^{-1}. After generating the sub-plasmalemmal HCMDs, which can reach concentrations as high as 10 to 100 µM (38, 471), Ca^{2+} redistributes into various intracellular compartments, particularly at the ER and mitochondria. This $[Ca^{2+}]_c$ elevation activates the SERCA and the ER avidly takes up Ca^{2+}; thus, during stimulation of bovine CCs (17, 640, 678) and rat CCs (295), the rate of uptake by the ER is about 60 µmol L cell^{-1} s^{-1}.

Mitochondria are highly effective in clearing $[Ca^{2+}]_c$ transients. Using mitochondria-targeted aequorin in bovine CCs maximally stimulated with K^+, it was found that mitochondria took up Ca^{2+} through their uniporter at about a rate of 1100 µmol L cells^{-1} s^{-1} (452, 453, 640). This value is close to that found for Ca^{2+} entry through Ca_V channels, meaning that most Ca^{2+} entering the bovine CC during stimulation is initially taken up by mitochondria and then released back into the cytosol through the mNCX. The rate of Ca^{2+} efflux through this transporter at 37 °C in bovine CCs is about 800 µmol L cells^{-1} s^{-1}; its kinetics are exponential and K_{50} approaches 20 µM Ca^{2+} (640). Finally, Ca^{2+} extrusion from the cytosol to the extracellular space depends on the activity of both SERCA and NCX. The joint action of both transporters decreases $[Ca^{2+}]_c$ at a maximal rate of 20 µmol L cells^{-1} s^{-1} in rat CCs at 27 °C (295, 504). In bovine CCs at 37 °C, this rate is close to 100 µmol L cells^{-1} s^{-1}.

After a brief opening of Ca_V channels in bovine CCs, an HCMD is formed near sub-plasmalemmal exocytotic sites (Figure 8). This HCMD has been estimated to have about 0.3-µM diameter and reach 10 µM or higher $[Ca^{2+}]_c$ (38, 129, 357, 442, 471–473). The formation of HCMDs is favored by colocalization of Ca_V channel clusters and secretory vesicles (490, 539, 690) to trigger fast exocytosis (54).

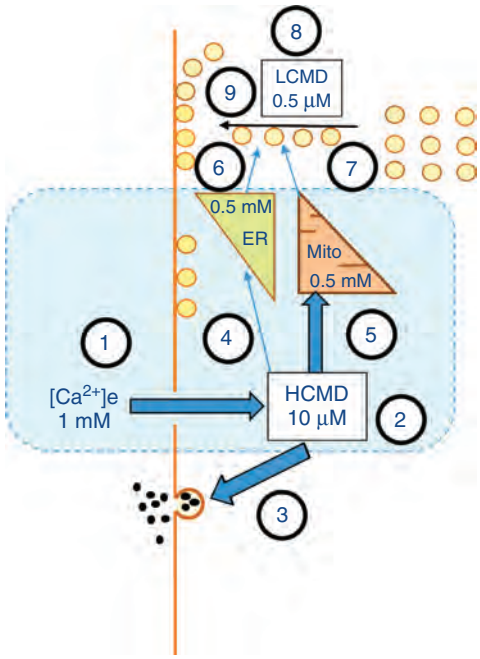

Figure 8 The concept of functional triads that regulate the generation of local $[Ca^{2+}]c$ transients and exocytosis responses upon stimulation of CCs. (1) After cell depolarization with the physiological neurotransmitter ACh, the voltage-dependent Ca^{2+} channels open. (2) Ca^{2+} enters the cell through a huge electrochemical gradient, giving rise to the formation of a high-Ca^{2+} microdomain (HCMD) of about 10 µM or higher near the sub-plasmalemmal exocytotic sites. (3) High Ca^{2+} is required to trigger the fast exocytotic release of CAs. (4) The HCMD quickly dissipates initially by mobile Ca^{2+} buffers (not drawn) and more slowly by Ca^{2+} uptake by the ER Ca^{2+}-ATPase (SERCA). (5) The second more relevant pathway for the clearance of the $[Ca^{2+}]c$ transient is the mitochondrial Ca^{2+} uniporter, which has a low-affinity high-capacity for Ca^{2+} sequestration into the mitochondrial matrix. (6, 7) In both ER and mitochondria (Mito), the matrix $[Ca^{2+}]c$ can reach near half a millimolar. ER Ca^{2+} can be released back into the cytosol through a CICR mechanism via ryanodine receptors, $InsP_3$ receptors (6), or through the mitochondrial Na^+/Ca^{2+} exchanger (7). (8) Ca^{2+} diffusion serves to redistribute Ca^{2+} at inner areas of the cell core to generate low-Ca^{2+} microdomains (LCMD) of around half micromolar that are required for the cytoskeleton-mediated Ca^{2+}-dependent vesicle traffic. (9) The Ca^{2+} levels of the LCMD refills with new vesicles the RRP at sub-plasmalemmal exocytotic sites, securing that new rounds of exocytosis take place, thus completing the exocytotic process.

The dissipation of HCMDs has two components. The fast one occurs in the time range of milliseconds and is associated to nearby cytosolic mobile Ca^{2+} buffers that accelerate Ca^{2+} diffusion and oppose the development of HCMDs (287, 480, 692). Consistent with this is the observation that added external Ca^{2+} buffers such as fura-2 increase the apparent rate of Ca^{2+} diffusion about fourfold (692).

The slower component of the $[Ca^{2+}]_c$ transient clearance is linked to the redistribution of Ca^{2+} into the ER and

mitochondria. This occurs particularly under conditions of intense stimulation of CCs. Using mitochondria-targeted aequorins with different Ca^{2+} affinities, two pools of mitochondria, M1 and M2, were characterized in bovine CCs (453). Mitochondrial pool M1, located near sub-plasmalemmal sites can sense the HCMDs occurring during physiological stimulation (295, 453, 504, 639, 640) (a local $[Ca^{2+}]_c$ rise of about 20 μM) and tune the mitochondrial generation of ATP to match the local energy needed for ATP-dependent vesicle docking at the plasmalemma and later exocytosis. Pool M2 exhibits a much lower rate of Ca^{2+} redistribution, which moves to inner regions to serve other functions, for instance, the intracellular transport of secretory vesicles from a RP to the readily releasable pool of vesicles (RRP) at sub-plasmalemmal sites (453, 640).

Concerning the functional role of ER Ca^{2+}, it is noteworthy that using ER-targeted aequorins, a reduction of 60 to 100 μM ER Ca^{2+} was observed in bovine CCs stimulated with high K^+, suggesting that CICR takes place during cell depolarization (17). RyR channels mediating CICR seem to colocalize with Ca_V channels and the mitochondrial uniporter of the M1 pool. Finally, after stimulation of CCs, the residual $[Ca^{2+}]_c$ released from the M1 pool of mitochondria and through the CICR mechanism from the ER is extruded out of the cytosol through the SERCA and the NCX.

We summarize our simplified view of the global Ca^{2+} handling by CCs in terms of what we refer to as a "functional triad" to shape the $[Ca^{2+}]_c$ transients. It has been proposed that functional triads formed by clusters of Ca_V channels, the ER RyR, and the mitochondrial Ca^{2+} uniporter are responsible for the generation and shaping of local sub-plasmalemmal $[Ca^{2+}]_c$ transients at the HCMDs that control the rate of exocytosis (17, 453, 640). Ca_V channels will act as the initiating signal, the RyR as the signal amplifier through CICR, and mitochondria as a barrier to limit diffusion further into the cell's core, where such HCMDs are not required. Ca^{2+} uptake into mitochondria has at least three functions, namely, to serve as a Ca^{2+} buffer, thus dissipating the large local Ca^{2+} transient; to redistribute the matrix Ca^{2+} into other mitochondria and the ER compartment into the cytosol; and to stimulate mitochondrial respiration and couple increased energy production to finely regulate the exocytotic machinery of the CC. As mitochondria release their matrix Ca^{2+} into the cytosol slowly, respiratory stimulation lags behind the cessation of cell stimulation, until the mitochondria Ca^{2+} load is completely cleared. Most Ca^{2+} taken up by mitochondria at sub-plasmalemmal sites may diffuse to other cell locations through the mitochondrial network, and eventually will be released near the cell core. Thus, mitochondrial Ca^{2+} release likely contributes, in a spatially specific way, to maintaining elevation of $[Ca^{2+}]_c$ after cell stimulation ends, to facilitate vesicle transport from a RP to a RRP (652). Ca^{2+} diffusion from sub-plasmalemmal sites to inner cytosolic sites is achieved by the propagation of a Ca^{2+} wave assisted by diffusible Ca^{2+} buffers and maintained by the CICR mechanism of the ER (17) (Figure 8).

From a physiological point of view, the concept of a functional triad suggests that plasma membrane Ca_V channels, together with the uptake and release of Ca^{2+} by ER and mitochondria, regulate Ca^{2+} handling in CCs. Ca^{2+} fluxes through these channels, and reservoirs are strongly activated during cell depolarization, but they also operate during inter-stimulation periods contributing to the Ca^{2+} homeostasis. Dysregulation of Ca^{2+} fluxes under pathological conditions at, for instance, the mitochondria will alter energy production and the exocytotic release of CAs. Recent experiments have demonstrated that Ca^{2+} handling and exocytosis of the sympathoadrenal axis and adrenal medullary CCs are altered in hypertension and various transgenic mouse models of neurodegenerative diseases (see below).

Exocytosis and endocytosis in CCs

Chromaffin granules

CCs are secretory cells and their most characteristic organelles are the CGs, which are very similar to the large dense-core vesicles (LDCVs) found in most neuroendocrine cells and neurons. In contrast to the synaptic vesicles found in neurons, CGs contain an intravesicular matrix that is visualized by electron microscopy as a dark structure within the CG. Granules are also of a larger size (≈200 nm) than synaptic vesicles (≈50 nm). Not only the size and matrix define CG, also the nature of their releasable cargo as they, beside amines and ATP, also release GABA, peptides, and granins. CGs contain astonishing concentrations of solutes whose resulted osmolarity would be expected to cause the swelling of CGs and their lysis. The ways used by nature to overcome the theoretical osmotic gradient from granule toward the cytosol have fascinated scientists for over five decades. A typical CG contains 0.8 to 1 M CAs, an estimated concentration of ATP of ≈200 mM, 40 mM Ca^{2+}, and significant amounts of peptides, nucleotides, and chromogranins. This inner cocktail, whose interaction enables the accumulation of neurotransmitters, is crucial for neurotransmission and for the successful secretion of hormones; processes that require the packaging of highly concentrated releasable cargo. Two components, chromogranins (166) and ATP (214), are essential for the accumulation of solutes. A concise description of the role of ATP and chromogranins contributing to the accumulation of adrenal CAs has been recently published (215).

The general view is that proteins that will form the granule matrix are synthesized in the ER, and protein assembly continues through the Golgi. CGs are produced in the trans-Golgi network by a budding process encapsulating the organized proteins that will form the matrix. The trans-Golgi network is also the sorting place for newly formed organelles. CGs are differentially sorted toward the regulated exocytosis pathway. A detailed description of the biogenesis and sorting processes occurring in neurosecretory cells is out of the scope of this article. However, excellent reviews have been published elsewhere (37, 604).

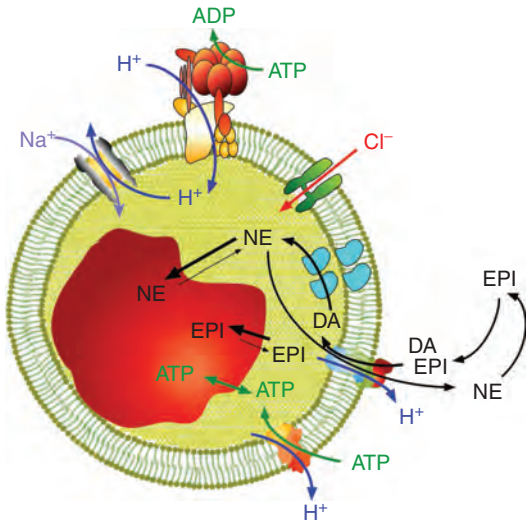

Figure 9 Main mechanisms involved in the accumulation of amines and ATP into the CG. A specific vesicular carrier (V-ATPase) pumps H^+ against a concentration and voltage gradient. To reduce the Ψ gradient, Cl^- channels open, allowing the pH to drop. The pH gradient is also regulated by Na^+ (and probably K^+) channels. Protons are used for exchange with CAs (dopamine, DA, or NE) or ATP. The synthesis of NE must occur inside the CG by the enzyme dopamine-β-hydroxylase (DBH, light blue) using DA as a substrate. In adrenergic cells, NE must leave the granule to be transformed into EPI in the cytosol (by an enzyme called phenylethanolamine-*N*-methyltransferase, PNMT, not shown) Most solutes bind the granule matrix, thus permitting their accumulation by maintaining the isotonicity of CG versus cytosol. Ca^{2+} is accumulated and released by a combination of H^+/Ca^{2+} exchange, Ca^{2+} pump, $InsP_3$-receptors (683), and ryanodine receptors (552). For clarity, Ca^{2+} turnover is not shown.

The inner milieu of CG is then further acidified from the Golgi value (pH ≈ 6.5) (555), and the matrix condenses to allow the uptake of amines, ATP, and Ca^{2+}. It is generally accepted that acidification will occur rapidly and that the uptake of cargo species starts immediately. This process is driven by an ATP-dependent specific H^+ pump, the vesicular proton pump (V-ATPase), which accumulates H^+ until the Ψ gradient reaches around +80 mV. To obtain the requisite lowering of pH, Cl^- enters CG acting as a counterion, and finally, the interior milieu reaches pH ≈ 5.5. Protons are then used as a counter-carrier to concentrate CAs, ATP, and Ca^{2+}. Thus, any alteration in the pH gradient will result in a loss of accumulation of these three species (94, 552). Most solutes will bind chromogranins, thus forming the granule matrix (Figure 9). It has been estimated that more than 90% of amines (669) and Ca^{2+} (552) are tightly bound to the matrix, thus forming a bicompartmental store, which will become important to determine the kinetics of exocytosis (558) and the participation of CGs in cellular Ca^{2+} dynamics (93). It should be noted that although CGs constitute approximately 20% of CC volume and contain Ca^{2+} at 40 mM, they do not appear to be a functionally important part of Ca^{2+}dynamics/regulation as are the ER, mitochondria, and plasma membrane (683) (Figure 9).

The complex process of secretion

As CCs are cellular machines evolutionarily optimized for secretion, they contain all the elements necessary to readily release solutes to the bloodstream. Each CC possesses around 12,000 CGs (671). The total amount of CAs present in both adrenal glands, if released instantly, would be a lethal dose for the organism. To prevent CA poisoning, CCs have multiple mechanisms to regulate secretion. An important initial limiting factor is that only a small fraction of CGs are available (the "readily releasable pool") for immediate release, with 70% to 80% of granules requiring further priming before they are available for secretion.

CG release occurs by regulated exocytosis, a Ca^{2+}-dependent process that entails the fusion of a CG with the plasma membrane. Roughly, exocytosis starts with the approach of a CG to the membrane, docking it and the formation of a fusion pore, and the expansion of the fusion pore allowing the release of CG products (cargo), followed by CG membrane recapture from the plasma membrane by a process called endocytosis. Exocytosis is common to most secretory cells, including neurons, and most of the molecular steps leading to vesicle exocytosis are shared by neurons and CCs. This has been one of the historical reasons for the use of CCs to unveil the mechanisms underlying secretion (470). Probably, the first evidence indicating that the secretion of neurotransmitters occurs by exocytosis was the finding of intravesicular proteins in the extracellular media after the stimulation of adrenal medulla. No other mechanism could easily explain how CgA (a soluble protein of ~70 kDa discovered in CGs) could cross the plasma membrane together with CAs (62). Once the mandatory role of Ca^{2+} for secretion was established (176, 360), the main question was to determine how Ca^{2+} entry could trigger a very energy-unfavorable reaction like the fusion of two membranes. The elucidation, mainly in CCs, of the main steps of protein-protein, lipid, and lipid-protein interactions involved in triggering and regulating exocytosis has taken more than 40 years of extensive research.

The sites of exocytosis, either in CCs and in synapses, are not widely distributed along the plasmalemma but restricted to specialized areas, active zone-like release sites. These regions, characterized by cytoskeletal elements arranged to direct SGs toward docking and fusion sites, are specifically enriched in lipids like cholesterol and PIP_2 (306, 363, 662), contain the acceptor proteins for fusion, and are relatively close to Ca_V channels, hence the fusion machinery is in close proximity to the Ca^{2+} source. Contrary to active zones in neurons, where the probability of exocytosis is high, the role or even the presence of the piccolo/bassoon anchoring proteins has not been described in CCs so far. Consequently, the transport of CGs to active zone-like release sites likely performed sequentially by tubulin and actin. F-actin was initially considered to fulfill a role as a cortical barrier that prevents the access of granules to the plasmalemma (39, 125, 642). This concept has evolved, and the cytoskeleton is currently considered a dynamic element, where a close interaction of actin filaments

with granules occurs (326, 369, 486, 592). Myosins II, V, and VI also seem essential for the delivery of granules from the Golgi to the periphery of the cell (545, 618, 641). Figure 10A illustrates our current view of the SG cycle in CCs. The F-actin cytoskeleton and myosin II could also be important for providing the "extrusion, squeezing" force needed for the fast release of neurotransmitters through the open fusion pore (466, 666).

The secretory machinery

The discovery that exocytosis can be selectively blocked by proteolytic neurotoxins like tetanus and botulinum toxins (359) indicated the existence of specific exocytotic proteins, as these toxins do not affect endocytosis (465). In addition, the discovery of the *N*-ethylmaleimide-sensitive factor (NSF) and the protein complexes involved in its action (the soluble NSF-attachment receptor complex or SNARE) (594, 595) started a stimulating scientific race to elucidate the molecular steps of regulated exocytosis. Although not all of the exocytotic steps have been defined, there is a general consensus about the main actors and steps involved in the process, which are summarized in Figure 10B (685). The so-called SNARE complex is formed by the interaction of one specific protein in the membrane of the granule (synaptobrevin or VAMP)

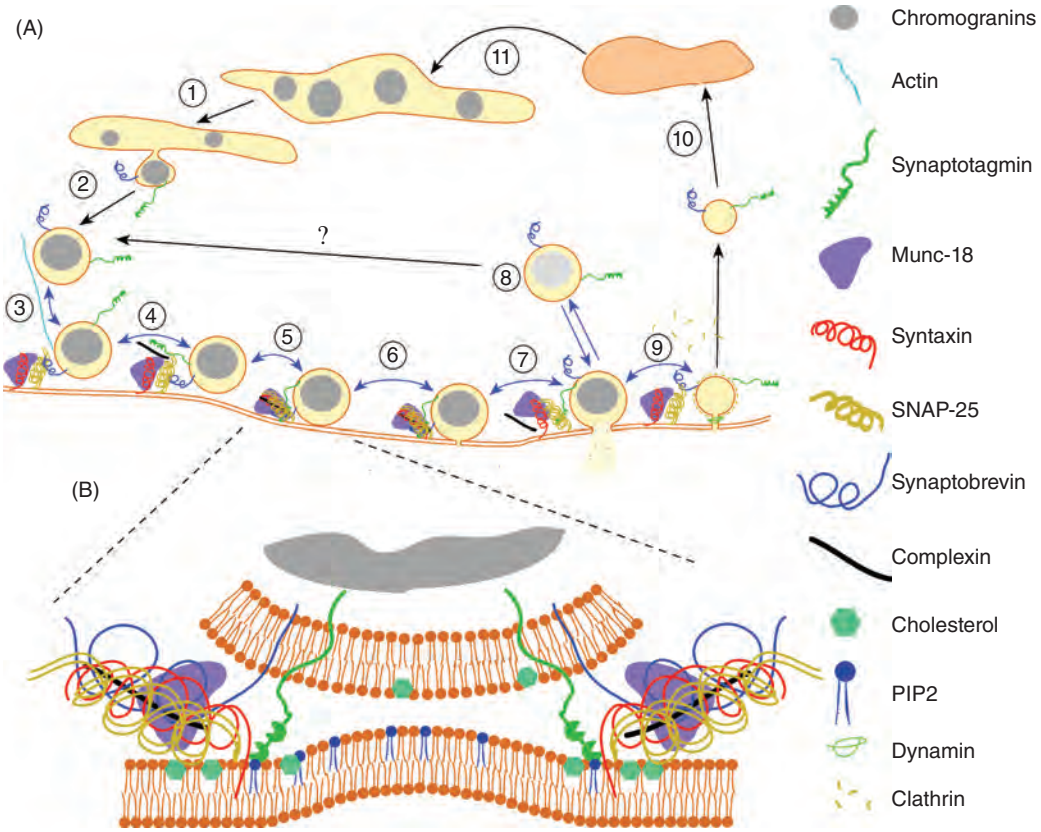

Figure 10 Exocytosis and endocytosis of CGs. (A) For clarity, only one SNARE complex is shown, while some of the accessory proteins are omitted: (1) granule proteins are sorted and packaged into the Golgi apparatus; (2) granules are transported to the release sites by tubulin (not shown); (3) actin filaments drive granules to specific tethering points; (4) "granule docking," the SNARE complex starts to organize and the granule docks to the plasmalemma; (5) priming, mediated by Munc-18 and complexin, thus allowing a tighter interaction of SNARE complexes. Munc13 acts on syntaxin changing its conformation, thereby leading to SNARE proteins zippering and the formation of fusion pore; (6) the initial fusion pore allows a limited exchange of water and solutes; (7) fusion pore dilatation allowing the partial or complete release of the granule content; depending on the extent of dilatation and duration of the Ω state, more or fewer solutes will be released. The SNARE complex is disassembled; (8) cavicapture. This partial exocytosis occurs when a dilated, but reversible, fusion pore allows the partial release of small molecules like peptides. Whether these granules can go to the SRP or get exocytosed again is unknown; (9) membrane recovery by endocytosis. Two major mechanisms might be involved: depending on clathrin and dynamin 2 or clathrin-independent that uses dynamin 1 to promote granule fission. The inner content of the granule rapidly acidifies; (10) clathrin is disassembled and the granule can travel deeper inside the cell toward either endosomes or lysosomes from where they can reenter in the secretory cycle after sorting in the Golgi (11). Note that sizes of the resulted endocytotic granules are now smaller, and granule matrices are clearer as a result of protein loss during exocytosis. Note also that some of the steps are reversible (blue double head arrows). (B) Organization of the SNARE complex in the priming state. The presence of cholesterol and lysophospholipids allows the curvature of the cell membrane. Note the lateral disposition of coiled-coil of proteins and the proposed situation of Munc-18 and complexin.

and two proteins at the plasma membrane (syntaxin and SNAP-25) (see Ref. 163 for a recent review). The exocytosis of CGs is much slower than that of synaptic vesicles, probably because despite using similar Ca^{2+}-triggering mechanisms and exocytosis machinery, they differ in the degree of preparation (docking) for fusion and in the composition of their vesicular matrix. Only six proteins, syntaxin, synaptobrevin, SNAP-25, Munc18-1, synaptotagmin, and complexin, form the core of the exocytosis machinery. Once the energetic barrier opposing membrane fusion is overcome, the interior of the granule is connected to the external media, thus starting the release of its contents.

The following are the currently most accepted steps involved in exocytosis (Figure 10B). The remodeling of the actin cytoskeleton allows SGs to get in contact with the plasma membrane (docking). At this stage, SNARE proteins are not yet fully associated. Ca^{2+} and the interaction of Munc13 and CAPS are crucial mechanisms involved in the priming process (423). Then, complexin binds to the SNARE complex, hence leaving it ready for Ca^{2+} action (super priming). Ca^{2+} will subsequently bring synaptotagmin to bind syntaxin, thereby promoting fusion pore opening (partial fusion). If Ca^{2+} concentration is sufficiently large or maintained long enough, the process evolves to "full fusion." Probably, there are intermediate steps between partial and full fusion. CCs possess two types of synaptotagmin (1 and 7), which have been implicated in the fast and slow components of the secretory response, respectively (528, 557). Ca^{2+} binds synaptotagmin at two binding sites (C1 and C2) to trigger granule fusion.

Pools of secretory granules

Since the first rudimentary recording of the time course of CA release (Figure 11A), it became clear that adrenal response decreased progressively regardless of stimulus persistence. This signaling "fatigue" is probably a physiological mechanism of defense to avoid the deleterious effect of oversecretion of CAs into the bloodstream, as occurs in some forms of adrenal pheochromocytoma (see below). This phenomenon is partially dependent on desensitization of nAChRs as well as Na_V and Ca_V channels (45). However, the "fatigue of secretory response" was also observed in the so-called leaky cell using either electroporation (43) or detergents like digitonin (184), indicating that the secretory machinery cannot maintain secretion for long periods of time, especially during strong stimuli (Figure 11B).

With the arrival of electrophysiological techniques, especially whole-cell capacitance, the phenomenon of "fatigue" was localized to the existence of distinct pools of granules (Figure 11C) with different probabilities of fusion (277, 387, 472). The nomenclature used to classify the differences in the release rate of CG populations varies from one research group to another, with sometimes confusing results. Hence, the granules that were ready to enter exocytosis in the first seconds after depolarization, as they are close to the "open mouths of Ca^{2+} channels" were considered to be in the immediately releasable pool (IRP). This pool would comprise only about 17 granules per cell in mouse CCs (582), although its exact size is difficult to determine as most studies were carried out in cultured cells whose channel distribution is significantly affected by denervation and adhesion to the cell culture surface.

Large Ca^{2+} entry, or sudden elevation of Ca^{2+} experimentally caused by uncaging of trapped Ca^{2+} using light pulses, will promote the release of about 200 granules from a CC within 20 to 40 ms when intracellular Ca^{2+} levels are around 20 μM (644). This is the rapidly releasable pool (RRP), which is observed by whole-cell capacitance as a rapid increase in cell surface resulting from the addition of granular membranes to the plasmalemma (Figure 11C). The analysis of the kinetics of release observed either by whole-cell capacitance or by integrating amperometric recordings shows that the rapid secretion from the RRP is followed by a slow phase of release from an RP or slowly releasable pool (SRP) with a time constant of ≈200 ms (644).

Finally, it should be noted that most CGs are either nonreleasable or are exocytosed only very slowly. The physiological role of this unreleasable pool has received little attention from scientists. Historically, it was considered as formed by immature granules that progressively move toward the releasable pools. However, novel experimental approaches have concluded that young granules will "jump the queue" and be the first released. This was shown using either total internal reflection fluorescent microscopy (TIRFM) with fluorescent dyes that changed color with age (180) or by analyzing the secretion of EGFP from CCs expressing EGFP-tagged neuropeptide Y (214) (Figure 11D). The classical theory uses a geographical distribution of granules to explain the kinetics of release, assigning to the RRP those granules situated near the membrane and to the RP those that are behind the actin barrier. TIRFM analysis suggests that only a small fraction of the granules that are already within the evanescent plane (<200 nm from membrane) do not get exocytosed and remain immobile for minutes regardless of the presence of stimuli. The unreleasable pool in CCs is about 70% to 80% of the whole population (≈10,000 granules per cell), and its physiological role is still unknown. Furthermore, it is the RRP that requires repletion, after its reduction by stimulation. Theoretically, refilling the RRP could be accomplished by (i) refilling of granules only partially exocytosed (kiss-and-run or cavicapture), (ii) formation of new granules after a short travel through endosomes, or (iii) the arrival of new granules to the cortical domain of the CCs. The precise contribution of each alternative is still under debate.

The exact contribution of the different pools to secretion is difficult to establish because of the Ca^{2+} dependence of both exocytosis and granule motion processes. However, the latter requires lower intracellular Ca^{2+} levels (≈1 μM) compared with the higher concentration required for exocytosis (>2 μM). These features have been used to determine the

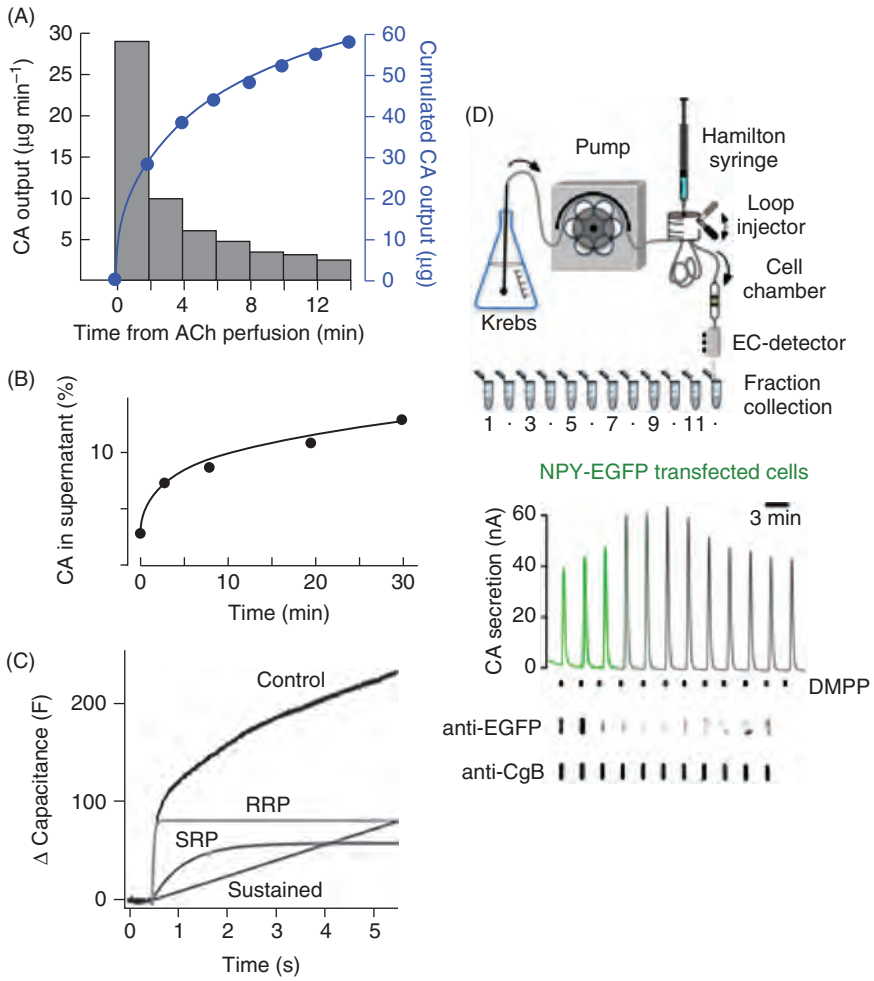

Figure 11 Different pools of granules are involved in the secretory responses. (A) Even in the continuous presence of Ach, the secretion of CA from perfused cat adrenals progressively decays (gray bars). Cumulative CA secretion is superimposed (blue trace). Modified, with permission, from Douglas WW, and Rubin RP, 1961 (176). (B) Although the time courses are different, a similar situation occurs when secretion is elicited by rising intracellular Ca^{2+} in permeabilized CCs (leaky cell). Modified, with permission, from Baker PF, and Knight DE, 1981 (44). (C) Recordings of whole-cell capacitance from mouse CCs evidence the presence of at least two exocytotic kinetics: rapid (RRP) and slow (SRP). Authors tested the effect of rising intracellular Ca^{2+} by flash photolysis of NP-EGTA (taken from Figure 2A in Ref. 591). Notice the different time course compared with panels A and B. (D) Newly produced granules are the first to be released. Perfused CCs are stimulated with a nicotinic agonist and CA secretion continuously recording by an electrochemical detector. The analysis of the perfusate shows that EGFP (labeling neuropeptide Y) is released only during the first pulses. Modified, with permission, from Estevez-Herrera J, et al., 2016 (214).

size and contribution to the secretion of RRP and SRP, that is by low versus high levels of intracellular Ca^{2+} released dose-dependently by controlled flash photolysis of Ca^{2+}-caged compounds (168, 643). An important limitation of the capacitance measurements to indicate the extent of CG release is the difficulty in determining, and subtracting, the contribution of endocytosis to the recordings. Capacitance change recordings might overestimate secretion as it also detects the fusion of granules that are devoid of CAs, a phenomenon observed when capacitance and amperometry measurements of exocytosis are compared (599).

Measuring exocytosis

Exocytosis from CCs has been measured by several methods including the chemical analysis of secreted products. However, the latter occurs too slowly for assessing a phenomenon that occurs in tens of milliseconds. For this reason, only modern live imaging, electrophysiological or electrochemical techniques, and the combination of them get a reliable time resolution. TIRFM uses the evanescent wave principle, by which excitation is restricted to ~150 nm beneath the cell surface situated in direct contact with the bottom coverslip. This noninvasive technique also allows examining the movement

of a granule prior to exocytosis and also membrane recapture. However, it requires the use of fluorescent dyes (170).

Cell capacitance change (ΔC) measurements with the patch-clamp are based on the notion that the cell membrane is a capacitor and its capacitance increases when the granule membrane fuses with the plasmalemma (or decreases when a portion of the membrane is retrieved during endocytosis). Modern equipment incorporates lock-in amplifiers to resolve exocytosis occurring at the whole-cell level. This is an invasive technique that permits control of the intracellular media but in general, is unable to resolve single-granule fusion events and is also blind to all phenomena occurring prior to fusion. The advantage of ΔC measurements is the monitoring of the whole-cell secretion and not just that restricted to the area covered by an amperometric electrode or the attached surface of a glass cover slide as in TIRFM measurements. The capacitance changes observed from a whole cell are the sum of two phenomena (exocytosis and endocytosis) that usually overlap. The RRP can be measured by applying strong stimuli to promote the fusion of the entire pool, whereas the refilling of this pool could be measured by the slower kinetics that follows the initial rise in capacitance (Figure 11C). One variation of the technique uses the cell-attached patch-clamp configuration to resolve single exocytotic events, allowing the study of the initial stages of fusion pore formation. These observations, however, are restricted to the patched area (386).

Electrochemical methods comprise amperometry and cyclic voltammetry. They detect the CAs released with a precise time resolution but do not detect other secreted species like ATP or peptides. This technique is noninvasive (the cell integrity is preserved), but it does not provide information about what happens to granules prior to exocytosis nor after their recapture (endocytosis). Voltammetry has less time resolution but allows the quantification of the released CAs. Single-cell electrochemistry also allows the analyses of the kinetics of exocytosis, including the pre-spike phenomenon—the so-called foot—that is associated with the escape of CAs through the fusion pore. However, some of the published data should be taken with caution unless proper calibration and correction for artifacts (e.g. use of the same calibrated electrode throughout the experiment, reduction of bias caused by changes in electrode responsiveness, and appropriate statistical analyses) are employed (69, 412). The kinetics of the exocytotic fusion pore can be resolved with high-resolution amperometric techniques (668). Thus, with a carbon-fiber microelectrode placed on the surface of a CC, several modes of exocytosis can be distinguished: (i) CA release occurs through a transient fusion pore that opens and closes without giving rise to full fusion and pore expansion, the so-called kiss-and-run; (ii) formation of a more stable fusion pore that, however, does not give rise to full fusion, the so-called kiss-and-stay exocytosis; (iii) formation of a fusion pore with subsequent expansion to release all vesicle content, followed by the collapse of the vesicle membrane and its integration in the plasmalemma, referred to as "full fusion" (630). Another interesting feature of the individual amperometric spikes is that many of them are preceded by a small "foot" (fusion pore formation) before the abrupt upstroke occurs (pore expansion and full fusion, see below) (130).

Finally, amperometry and cell-attached capacitance measurements have been successfully combined for simultaneous measurements (9). This technique, called patch amperometry, allows the direct characterization of fusion pore and the direct measurement of granule content of CAs (254, 454). The main disadvantage of this procedure is its technical difficulty.

Partial versus full exocytosis

Classically, exocytosis has been considered as an all-or-none process. The concept of partial exocytosis, that is when only one part of the granule content is released upon fusion, was first suggested by Bruno Ceccarelli in frog neuromuscular junction (119). This phenomenon, however, received real attention only after it was observed in mast cells and CCs (9, 18) and has finally gained acceptance as a technology for measuring secretion evolved. The stable and reversible formation of a fusion pore allows the release of cargo species through its limited diameter and lasting duration (170). There is not a general consensus about the definition of the fusion pore: the concept ranges from a channel-like structure (with a diameter of 1–2 nm), measurable by capacitance, to a wider Ω-shaped vesicle as observed by electron microscopy (of about 20–30 nm in size). The former probably is governed by a mixture of lipids and proteins, whereas the expanded pore seems to be composed only of lipids (574). Nevertheless, it is now accepted that most of the exocytotic events are partial, and the granule usually retains a significant fraction of its content after fusion. This comprises both low molecular weight species such as CAs and high molecular weight proteins such as chromogranins and their fragments.

The comparison of the quantum size measured in the same cell cultures by amperometry and patch amperometry (455) or by "electrochemical cytometry" (181) indicates that only about 30% of CAs are released in most of the exocytotic events. In addition, the monitoring of fluorescent-labeled CgA (chromogranin coupled with EGFP) by TIRFM shows that most granules retain some fluorescence after fusion (170). An emerging novel concept about the regulation of secretion of CAs comes from the amount released during partial exocytosis (491). It seems that strong stimuli tend to favor full release, whereas mild stimulation triggers partial release. The main regulators of this process seem to be the intracellular Ca^{2+} concentration (199) and cAMP (413). The nature and physiology of the fusion pore have been recently reviewed (19).

Endocytosis

The increase of membrane resulting from secretion or constitutive exocytosis has to be compensated by membrane retrieval. This fission process is called endocytosis, and it is necessary not only to maintain constant the membrane surface

but also for renewal of proteins and lipids from the membrane. This latter type of endocytosis, named "constitutive," is common to all cells and it is not dependent on Ca^{2+}. Constitutive endocytosis is used to retrieve receptors, carriers, and channels, and it is essential for downregulation processes common to transporter activity, receptor desensitization, and, more generally, cellular responsivity (285, 649). This is a slow process, and does not necessarily occur at the site of exocytosis even for proteins involved in the exocytotic process itself.

Triggered endocytosis occurs in CCs rapidly after exocytosis (Figure 10). Plasma membrane internalization does not occur randomly to maintain the total surface stable. Rather, despite full fusion, exocytosed granules and plasmalemma maintain their specific protein and lipid composition. This exo-endocytosis coupling was first observed by morphological studies showing that granule membrane-bound components are retrieved after exocytosis (507). Also, a large increase of *coated pit* structures containing granule components immediately after stimulation of CCs was observed by electron microscopy (245). The endocytosis process seems to occur at the same lipid-raft structures where exocytosis took place. These areas are enriched in both cholesterol and phospholipids like PIP_2 (322). Taken together, these data indicate that exocytosis and endocytosis are tightly coupled phenomena intended not only to maintain the cell surface constant but also to recapture most of the granule membrane components and part of the granule matrix.

In CCs, two endocytic pathways exist: a rapid endocytosis, which takes place in tens of milliseconds to a few seconds, and it is probably associated with cavicapture and kiss-and-run secretory modes (605), and a slow clathrin-mediated exocytosis (200). Rapid endocytosis does not require clathrin and seems to involve GTP, Ca^{2+} (85, 541), and dynamin-1 (34). The clathrin-mediated endocytosis is the best-studied and involves clathrin and dynamin-2, but not Ca^{2+}; this slow endocytosis occurs in tenths of seconds and can last for minutes (200). Dynamins are envisaged to function in constricting the fusion pore and promoting the formation of an endocytic vesicle capable of traveling toward the cell interior. It is, therefore, possible that these proteins can also regulate the amount of cargo released during each exocytotic event. Data derived from dynamin manipulation in CCs are still contradictory (128, 233). Even the expression of dynamin-1 in CCs has been questioned (255). Likewise, the functional role of amphiphysin, another protein involved in fusion pore constriction in other tissues, has not been conclusively established in CCs.

Endocytosis often results in retrieving more membrane than that previously incorporated during exocytosis. This excess retrieval is faster than rapid endocytosis and seems to be triggered by different mechanisms (207, 579) unlinked to exocytosis and at a rate that could internalize approximately 10% of the total cell surface within a few seconds (49). Excess retrieval is frequently accompanied by the formation of large nonreleasable endosomes (611). This formation of large endosomes during excess retrieval is called "bulk" endocytosis (111, 533) (for clarity, this is not shown in Figure 10).

Clathrin-dependent membrane retrieval produces vesicles of 50 to 100 nm, notably smaller than CGs (180–250 nm). The discrepancy in size suggests that the membrane from CGs can be recaptured as small pieces rather than as a whole (311). Both recycling from partial exocytosis and a degradation pathway from full granule collapse coexist, and their fraction may depend on secretory activity, as mentioned above. Vesicles resulting from the endocytotic clathrin-mediated pathway might go to early endosomes to produce new granules or fuse with lysosomes for degradation. The degree of contribution of both pathways and their regulation is not known. Since retrieved vesicles are composed of pieces from CGs and not as a whole, the early endosomes could be a transient organelle where endocytic vesicles are repackaged to reconstitute functional granules before going to the retrograde transport pathway to the trans-Golgi network (311). Using specific antibodies against membrane-bound granule proteins, it was shown that they were taken up through clathrin-mediated vesicles and internalized toward lysosomes (56). These proteins were then found in the trans-Golgi, and a few hours later were localized in newly formed granules (507, 649) (Figure 10A).

From *kiss-and-run* to full granule collapse, there are different degrees of exocytotic modes. The same can be said for endocytosis where several mechanisms for membrane retrieval coexist. Capacitance changes and patch-amperometry studies conclude that the fusion pore can open and close (or "flicker"); this suggests that this transient structure can be reversible at least up to certain pore size. Therefore, kiss-and-run retains membrane and most of the matrix proteins of CGs. The limit for reversibility for CGs is around 3.4 nm, as larger sizes convert fusion to an irreversible process (9, 15). However, observations using TIRFM (512) and fluid-phase capture (650) suggest that even larger pores are reversible. Many CGs reseal in a few seconds after exocytosis. These granules are rapidly acidified (606) and might be partially or completely empty of CAs and other soluble components (599). The physiological contribution and importance of the cell mechanisms operating, for the various modes of exocytosis/endocytosis, opens exciting research prospects for the coming years.

The Sympathoadrenal Medulla Axis in Stress Responding: Roles of PACAP, Other Transmitters and Peptides, and Organ Remodeling

PACAP as a stress transmitter at the splanchnicoadrenomedullary synapse

The ability to generate an AP via nAChR-dependent Na^+ channel activation on CCs explains how ACh acts as a secretagogue for EPI release from the adrenal medulla (see the

preceding sections). In the late 1970s, however, the possibility of adrenomedullary CA secretion by first messengers other than ACh began to emerge. The Wakade laboratory in particular, explored the long-term changes in CC content driven by high stimulation rates thought to be typical of the frequency of firing of the splanchnic nerve during stress. It was discovered that the adrenal medulla releases an amount of CAs equivalent to its entire initial content during a bout of secretion lasting several hours. Yet even after such prolonged secretion, CCs remain able to continue CA secretion, due to constant CA repletion via biosynthesis during the secretory episode (see (576, 659) for similar observations in the calf adrenal gland). How the adrenal gland resynthesizes its entire store of accumulated EPI, as well as its complement of releasable proteins and peptides, following prolonged and even acute but intense secretion, has been a subject of considerable investigation, subsumed under the rubric of "stimulus-secretion-synthesis coupling" (3, 190). One mechanism for enhanced repletion of CAs linked to increased depletion by secretion was discovered in the 1970s by Costa and Chuang. They learned that exposure to cold, which is associated with massive sympathoadrenal activation, causes an increase in the total capacity to convert tyrosine to L-Dopa within the adrenal medulla (126), due to induction of tyrosine hydroxylase (TH), the rate-limiting step in CA biosynthesis (131). Since nicotinic cholinergic stimulation has a limited ability to induce TH as well as peptide synthesis in the gland, it was concluded that this "stimulus-secretion-synthesis coupling" might be afforded by activation of mAChRs on CCs following enhanced splanchnic nerve stimulation during episodes of stress (217). It was noted subsequently, however, that reflex stimulation of the splanchnic nerve *in vivo*, by pharmacological treatment with reserpine, caused an induction of TH that could not be reversed by blockade of either nicotinic or muscarinic receptors, and these authors concluded that either a novel type of cholinergic receptor was expressed on CCs, or that a noncholinergic substance might be released along with ACh from the splanchnic nerve, to allow TH induction under conditions of stress (610). Similarly, stimulation of the sympathetic trunk at high frequency also causes TH induction in the postganglionic sympathetic neurons of the superior cervical ganglion, and this also occurs by a mechanism only partially accounted for by action of ACh released from preganglionic terminals (318).

The discovery of the neuropeptide PACAP (447) by Miyata, Arimuraa, and colleagues in 1989 finally offered a clue to the identity of this additional sympathetic neurotransmitter. PACAP, as its name implies, was initially discovered as a hypothalamic peptide able to stimulate cAMP production in cells of the anterior pituitary. However, it was subsequently learned that the physiological role of PACAP extends far beyond its role as a hypothalamic releasing factor, to that of neurotransmitter in both brain and autonomic nervous system (26). In particular, and consistent with a potential role as a splanchnicoadrenomedullary transmitter along with ACh, PACAP potently stimulates EPI secretion from the adrenal gland *in vivo*, from the perfused adrenal gland, and from CCs in primary culture (155, 265, 270, 302, 600, 663; and references therein).

The localization of PACAP to the splanchnic nerve innervating the adrenal medulla required the creation of mice genetically deficient in PACAP expression. This in turn allowed the certification of antibodies to PACAP that could be shown clearly to detect PACAP specifically, especially compared to the very closely related neuropeptide VIP, in the cholinergic nerve terminals of the splanchnic nerve (269). The role of PACAP in stress-induced CA release and biosynthesis in the adrenal medulla was further examined with the aid of PACAP-deficient mice. Injection of insulin lowers blood glucose levels and stimulates maximal reflex firing of the splanchnic nerve, causing greatly elevated blood EPI levels and enhanced TH activity in the adrenal gland: these effects were blunted or abolished in PACAP-deficient mice. PACAP-deficient mice could be rescued from death after prolonged hypoglycemia by treatment with either PACAP or glucose (269). In adrenal slices taken from the mouse, EPI secretion upon splanchnic nerve stimulation at high frequency (2 Hz), but not at low stimulation rates (0.2 Hz), is blocked by the PACAP antagonist $PACAP_{(6\text{-}38)}$ and is abrogated by PACAP deficiency (i.e. is absent in slices from PACAP-deficient mice) (368, 593).

In summary, PACAP is colocalized with ACh (i.e. the cholinergic vesicular marker VAChT) at nerve terminals of the splanchnic nerve that innervate CCs in the mouse. Stress-induced CA secretion and TH regulation require the expression of PACAP. Experiments with adrenal slices *ex vivo* show that this PACAP dependence occurs at the level of the splanchnic nerve itself, and is probably due directly to the release of PACAP there, since the morphology and chemical neuroanatomy of the splanchnicoadrenomedullary synapse in PACAP-deficient mice are otherwise normal. These experiments suggest that PACAP released at the adrenomedullary synapse mediates CA secretion from the adrenal medulla during stress (see Figure 12) (189, 580). Residual CA release provoked by prolonged hypoglycemia even in the PACAP-deficient mouse suggests that ACh also contributes to stress-induced CC CA secretion *in vivo* (269), consistent with the many previous reports of high-frequency CA secretion from the adrenal glands of various mammalian blocked by nicotinic and muscarinic antagonists (342, 356, 364, 374, 623, 658, 684). Of relevance to this issue are the observations of Arun Wakade's lab on isolated perfused adrenal glands from rats (657). The group reports that prolonged high-frequency splanchnic nerve stimulations (10 Hz for >3 h) produce the massive release of CA that is almost completely abolished (>80%) by cholinergic receptor antagonists, while sustained low-frequency stimulations (1 Hz for >6 h) are effectively controlled (>60%) by noncholinergic receptors activation (PACAP and VIP) (422, 656).

It is evident from the above arguments that the relative contributions of ACh and PACAP at the splanchnicoadrenomedullary synapse during high levels of splanchnic

INFORME DE LABORES 2019

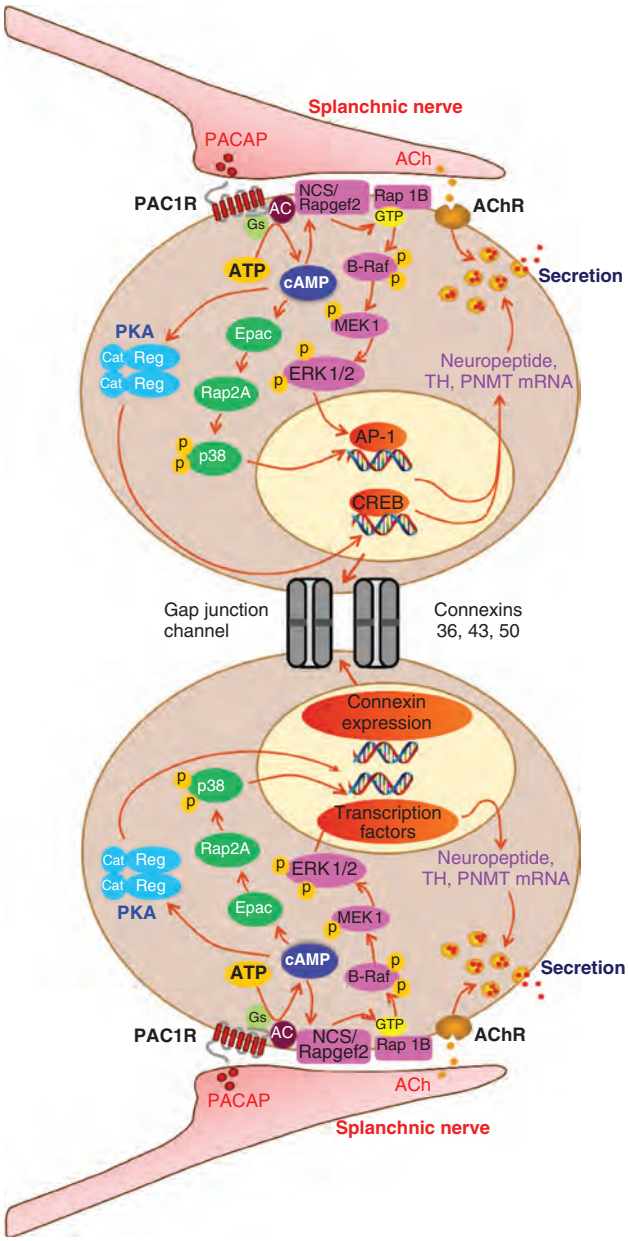

Figure 12 Intracellular signaling pathways and physiology of the chromaffin cell. Acetylcholine and PACAP (sympathetic preganglionic) release from splanchnic nerve activates the nicotinic (AChR) and PACAPergic (PAC1R) receptors, triggering catecholamine and neuropeptide secretion from CG, and increased transcription of genes encoding biosynthetic enzymes for catecholamines (TH, PNMA), and prohormones from which processing to mature neuropeptides occurs, and stimulus-secretion-synthesis coupling in the chromaffin cell. PAC1R activation promotes Gs coupling to adenylate cyclase (AC), the elevation of cyclic AMP (cAMP), and the activation of three separate cAMP effectors. Protein kinase A (PKA) mediates CREB-dependent gene transcription; Epac mediates Rap-dependent activation of the MAP kinase p38, leading to activation of transcription factors including AP1; NCS-Rapgef2 mediates Rap-dependent activation of the mixed-function kinase B-Raf, allowing MEK upregulation of the MAP kinase ERK (extracellularly regulated kinase) and gene activation through a combination of transcription factors. Stimulus-secretion-synthesis coupling also involves on the intercellular level increased expression of connexins that form gap junctions, which help to amplify chromaffin cell secretion from the adrenal gland as a whole. There is as yet no direct proof for PACAP or acetylcholine as the principal mediator of what might be termed the "gap-junction response." IFN, TNF, IL-1, and IL-6 effects on cognate receptors on chromaffin cells and cellular sequelae in the chromaffin cell are not shown, but synergize with PACAP stimulation to modulate both catecholamine and peptide secretion and chromaffin cell gene transcription. Splanchnic nerve input affords synergistic as well as antagonistic interactions between cytokines and PACAP under physiological conditions in which both stress and inflammation may play a role. Finally, secretory products of the chromaffin cell itself, including substance P, other neuropeptides, and chromogranin-derived peptides such as catestatin, modulate chromaffin cell secretion via paracrine actions, in part through modulation of AChR function. See text, and references in text, for further details.

nerve stimulation that occurs during stress may vary significantly across mammalian species. Like ACh, PACAP stimulates secretion of CAs from the adrenal *in vivo* or from CCs in primary culture, in mice, rats, cows, dogs, humans, and other mammals (reviewed in Ref. 270). In terms of PACAP action at other sympathetic ganglia/synapses, there are well-documented PACAP actions at sympathetic postganglionic neurons, at least in culture, that include secretion and changes in gene expression, suggestive of a role for PACAP in stimulus-secretion-synthesis coupling at sympathetic as well as sympathoadrenal synapses (53, 440). Postganglionic parasympathetic neurons of intrinsic ganglia of the heart are also PACAP-responsive (620). These findings support the concept that PACAP acts as an effective neurotransmitter, along with ACh and NE, in the autonomic nervous system. It is also evident that understanding the details of the specific roles of this stress-inducing neurotransmitter in supporting ACh-driven secretion and gene expression in the adrenal medulla deserves further investigation.

Implications of PACAP transmission for GPCR-mediated stimulus-secretion-synthesis coupling in the CC during stress

Endocrine cells, in general, the must maintain their stores of secretable material, even during intense episodes of stimulation and secretion, to preserve their efficacy for future homeostatic responding. Secretion and synthesis need not be coupled processes if they occur at about the same rate constitutively. This is rarely the case, however, as hormone secretion is commonly episodic, occurring in response to varying homeostatic demands. Repletion of hormone content lost by secretion from endocrine cells could occur by several mechanisms, but two mechanisms seem to dominate for the CCs of the adrenal medulla. The first is a chronic overproduction of prohormone protein relative to the storage capacity. In this case, the excess hormone is degraded at times of low secretory activity, and diverted to the secretory pathway at times of high secretory activity and demand. CgA, the major protein constituent of the CG, appears to be regulated in this way. Since CgA is a component in the process of SG biogenesis itself, the CC can package no more CgA than there are available vesicular membranes to contain it. At rest, and when the CG complement is maximal, excess chromogranin is apparently degraded in the trans-Golgi network, and when the CG complement is depleted by an episode of secretion, this excess is redirected toward granule production. This mechanism allows CgA levels (and CGs) to be maintained at a sufficient level across even prolonged episodes of secretion without the need for compensatory increases in chromogranin mRNA abundance and protein synthesis (191, 227). For (pro)hormones that represent a smaller fraction of total SG protein content, and are therefore not "rate-limiting" for CG biosynthesis, and also for CAs, however, a regulatory mechanism must exist to compensate hormone lost from the cell by secretion, via enhanced hormone biosynthesis.

The hypothesis of stimulus-secretion-synthesis coupling arose during the search for this second mechanism of the hormone loss and repletion cycle, which centered on whether or not secretagogues, while stimulating the release of stored hormones, signal at the same time to the nucleus to activate transcription of the specific genes responsible for hormone biosynthesis (190). For bioactive peptides produced by prohormone processing within the CG, this is accomplished by an increased rate of transcription of the prohormone gene and subsequent increase in translation of its mRNA into the prohormone, which is then processed into mature peptide(s). In the adrenal medulla, the "secretory cocktail" is a mixture of protein (chromogranins and processed neuropeptides) and small molecules (CAs, ATP, and GABA), and stimulus-secretion synthesis coupling must occur for both categories of secreted material. Thus, binding of secretagogues to their receptors stimulates Ca^{2+} influx, activation of CG exocytosis, and release of CG contents. Simultaneously, secretagogue signaling stimulates transcription of prohormone protein-encoding genes as well as biosynthetic enzymes responsible for CA and another small-molecule biosynthesis. In the case of CA production, this means activation of TH through phosphorylation at key serine/threonine residues, and increased production of the TH protein itself, through enhanced transcription of the TH gene (276).

The cellular mechanisms for stimulus-secretion-synthesis coupling in the adrenal medulla have been well investigated throughout the 20th century and have functioned as a model for understanding this process in other types of endocrine cells (Figure 12). The second messenger most prominent in regulation of stimulus-synthesis coupling is Ca^{2+}, consistent with its role in stimulating secretion in most endocrine cells. In the adrenal medulla, cAMP was implicated early in both the transcriptional and posttranslational phases of TH activation. Study of stimulus-secretion-synthesis coupling related to co-stored peptides such as substance P, NPY, enkephalin, and galanin revealed that while cAMP appears to be the main second messenger for activation of gene transcription of the genes associated with these peptides, cAMP-dependent gene activation by the classical third messenger protein kinase A (PKA) was not always clearly identified as a regulated step in the process.

Kuo and Greengard (367) initially proposed that PKA was the sole effector for cAMP in mammalian cells. It was later discovered that cAMP gates Ca^{2+} channels on some mammalian cells (81), and that in addition, many non-PKA and non-Ca^{2+}-dependent cAMP-initiated signaling events exist in mammalian cells, especially neuroendocrine cells. In the 1990s, two proteins within the family of Rapgefs (rap-activating guanine-nucleotide-exchange factors) were identified as cAMP-regulated enzymes. These two proteins are most commonly called EPAC1 and EPAC2 (other names include Rapgef 3 and 4, or cAMP—GEF1 and 2 (72, 158, 341). The EPACs extended the range of cAMP effectors—from protein kinases to guanine-nucleotide-exchange factors—and also brought into the

stimulus-secretion-synthesis coupling pathway downstream signaling molecules activated preferentially by Rapgefs, such as the MAP kinase ERK (Figure 12) (202, 204, 205).

For example, galanin biosynthesis in the CC was found to be regulated by PACAP via a non-PKA-dependent cAMP signaling pathway acting through ERK (203). Experiments in cellula allowed the identification of a Rapgef cAMP effector molecule, Rapgef2, in this pathway, by both loss-of-function after gene ablation and gain-of-function after expression in nonendocrine cells (202). The Rapgef2 gene emits two classes of transcripts by alternative splicing, now called NN (for nonneuronal)- and NCS (for neuritogenic cAMP sensor)-Rapgef2. NCS-Rapgef2 is expressed mainly in neuronal and endocrine cell types/tissues in adult rodents and other mammals, and links cAMP elevation to ERK activation in CCs, in neurons, and in pancreatic beta cells (324). The initial discovery of NCS-Rapgef2 in the CC has led to the understanding that cAMP signaling in these and other endocrine cells and neurons is parcellated among at least three effectors, NCS-Rapgef2, EPAC, and PKA, that independently signal through distinct Rap isoforms (NCS-Rapgef2 and EPAC), and through CREB and other threonine/serine kinase acceptor proteins, to mediate distinct and separate cellular functions (204, 305, 324, 347, 403, 544).

A relevant emerging question is how PACAP receptor activation, since it does not involve the opening of sodium channels, engages the machinery for Ca^{2+} influx in the CC. A plethora of reports on this subject convey the general impression that Ca^{2+} channel opening via activation of the PAC1 receptor (PAC1R) is likely to involve initial cAMP-dependent phosphorylation of Ca^{2+} channels themselves, albeit the mechanisms ultimately responsible for secretion and regulation of gene expression for CA and secretory protein biosynthesis by PACAP in CCs will require additional investigation (*vide supra*).

The role of peptides secreted from the adrenal medulla

The discovery that bioactive neuropeptides, in particular opioid peptides are released along with CAs from the CCs of the adrenal medulla provided a source tissue for the isolation of the prohormones for the enkephalins, and later the mRNAs encoding them (135, 380, 381, 395). These developments were in turn made possible by the earlier identification of chromogranins as secreted proteins of the adrenal medulla (*vide infra*) and the discovery that enkephalin peptides are a major constituent of CGs (380, 395). Progress in understanding the generation of small opioid peptides from larger precursors led in turn to the realization that CgA is itself a prohormone, generating the bioactive peptides pancreastatin, vasostatin, catestatin, and others (188, 281, 313, 608). One of the proenkephalin-derived peptides found to exist in CGs BAM-22P was structurally identified through a systematic peptidomics analysis of the CG (448). Likewise, the novel bioactive peptide adrenomedullin was identified, in extracts of CC-derived human pheochromocytoma tissue, similar to PACAP extracted from the hypothalamus, via a proteomics-based search for novel cAMP-elevating neuropeptides (354). The finding of a highly variegated secretory cocktail, including CgA and enkephalin-derived peptides, as well as substance P, galanin, and NPY, also later shown to be prohormone derived, increased appreciation that the CC might participate in organismic endocrine regulation through these peptides as well as via the release of CAs. The ability to determine where, and how, these peptides exerted their physiological roles was initially made difficult by ignorance of the location of their receptors, which might suggest their autocrine, paracrine, or hormonal actions *in vivo* (281). Indeed, the molecular nature of the receptor for catestatin, one of the CgA-derived peptides of the adrenal medulla, is still uncertain. Catestatin, for example, inhibits ACh-induced CA secretion from CCs, but not that caused by potassium depolarization, by the Ca^{2+} "agonist" barium, or by ionophores that mobilize Ca^{2+}, suggesting that catestatin acts through a receptor that either is or acts immediately downstream of the nAChR of CCs (420). In PC12 cells, catestatin affects not only ACh-induced but also PACAP-induced CA secretion, suggesting that it may act to modulate both resting and stress-induced adrenomedullary secretion (549). Thus, catestatin may function as an autocrine regulator of CA secretion and biosynthesis, based on its negative modulation of nAChR activation in CCs, as has been suggested for substance P produced in CCs (84, 310, 396).

Catestatin has multiple effects on distant organs, suggesting a hormonal role, in addition to its autocrine functions within the adrenal medulla itself. It is noteworthy that, given the presence of several other bioactive peptides within the CgA primary sequence, administration of catestatin alone rescues the major aspects of the CgA-deficiency phenotype in CgA-knockout mice (416). Catestatin and other chromogranin-derived peptides affect virtually all stages of the secretory function of the CC (416), including CG biogenesis (353), and this function appears to be shared with other granin proteins in CCs (455). Modulation of CA release is a major function of catestatin that is increasingly well defined pharmacologically (622). Physiologically, catestatin not only modulates CA release, but, as a hormone in its own right, acts in synergy with CAs on cardiovascular function and metabolism, and regulation of other endocrine cells and immunocytes, and their metabolism and secretory morphology (348, 588). Other CgA-derived peptides with potent effects on heart and vasculature are reported, including vasostatin, and these potential hormones create multiple regulatory linkages among adrenomedullary secretion, metabolic function, and muscle performance, and therefore between stress transduction and cardiovascular and metabolic physiology (279).

Another adrenal medulla-derived neuropeptide worthy of consideration is adrenomedullin, which was discovered as a constituent of human pheochromocytoma (354). Adrenomedullin activates a GPCR linked to Gs, and its receptors are found throughout the cardiovascular system.

It has profound hypotensive properties and thus could be envisaged as a counter-regulator or modulator of CA actions. Unlike peptides present at only low levels in CCs, for which autocrine and paracrine are more likely than hormonal ones (*vide supra*), adrenomedullin, like catestatin, may function as a bona fide hormone, like the CAs, in mammalian physiology, as well as a paracrine/autocrine factor in the adrenal medulla itself (25) in addition to actions at sites of local synthesis outside of the adrenal medulla. The possible functional role of adrenomedullin in the regulation of the heart, vasculature, and kidney has been studied, and this peptide shows some promise for clinical utility (186).

The role of peptide hormones of the adrenal medulla, including CgA, CgA-derived peptides, opioid peptides, NPY, substance P, adrenomedullin, and others, has opened a new and important avenue of adrenal medulla physiology. These peptides and their receptors represent adaptive components of the endocrine network and their fine-tuning of homeostasis, throughout mammalian evolution, including the tissue-specific production of specific hormones and the tissue-specific expression of their receptors. BAM22P, for example is a 22-amino acid peptide that is proteolytically processed from proenkephalin almost exclusively in the adrenal medulla, perhaps because the uniquely slow or incomplete processing of this opioid prohormone in the adrenal CC, unlike in neurons, generates a multitude of peptide "processing intermediates," which are characteristic of the adrenal medulla. BAM22P appears to be one of these which is uniquely bioactive upon release, because its receptor is expressed mainly within sensory neurons. This receptor prefers BAM22P to met-enkephalin with a potency ratio of greater than 50-fold. Consistent with this preference, the BAM22 receptor is only distantly related to the μ-opioid receptor, for which enkephalin pentapeptides are thought to be the main endogenous ligands (377). The expression of the BAM22P receptor in sensory neurons, together with high concentrations of BAM22P contained in and therefore secreted from the adrenal medulla, invites the speculation that BAM22P may act as a transmitter or paracrine factor for cross-communication between CCs and the sensory nerves that innervate the adrenal gland (505) (see Figures 12 and 13).

The concept of organ plasticity in stress responding of the adrenal medulla

During development, endocrine organs arise as cell colonies with a very specific secretory mission. Some are spatially quite compact, as the adrenal medulla, and others dispersed throughout other organs, such as the cells of the endocrine pancreas and the entero CCs of the gut. Regardless of their physical coherence, it is generally considered that each cell within an endocrine organ acts in parallel with, but independently of, its neighbors in hormone secretion in response to the presence of secretagogues. The detailed study of vasopressin secretion from the posterior lobe of the pituitary, however, caused a reappraisal of this point of view. Several investigators began to advance the idea of a concerted function of the secretory cells as a cohort, through cell-cell communication about the secretory status of individual cells, with integration to the function of the entire gland (80). This perspective allows endocrine organs to be viewed not only as a "massively parallel" system, but takes into account plasticity in the secretory status and responsivity of individual cells in response to secretory demand and even organismic

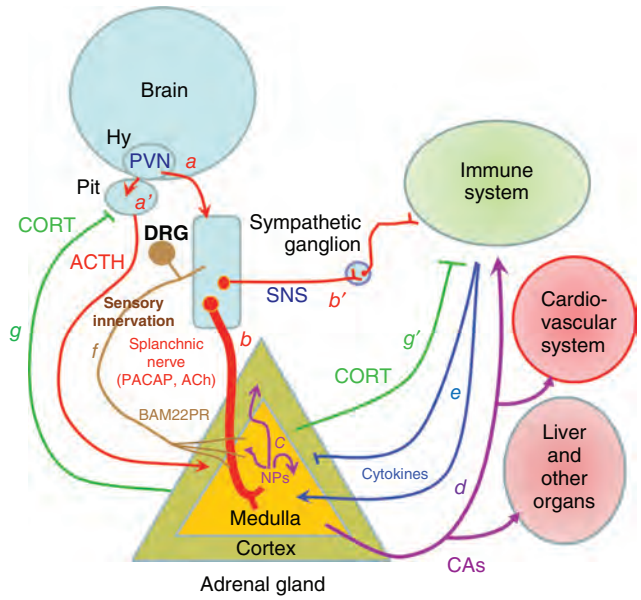

Figure 13 The adrenal medulla as a stress transducer and neuroimmunoinflammatory and cardiovascular regulator. Lower figure. a. The "final common pathway" for stress responding in the CNS is the activation of neurons in the paraventricular nucleus (PVN) of the hypothalamus (Hy), which projects both to the cell bodies of sympathetic preganglionic neurons in the intermediolateral column of the spinal cord and to the median eminence: a′. for ACTH release from the pituitary (Pit) to stimulate corticosterone/cortisol (CORT) release from adrenal cortex; b′. cell bodies in the intermediolateral column of the spinal cord innervate the CCs of the adrenal medulla via the splanchnic nerve, and sympathetic postganglionic nerve targets via para- and prevertebral postganglionic sympathetic neurons b. via the splanchnic nerve, releasing ACh basally, and ACh and PACAP during stress, with activation of both secretion by ACh and PACAP, and of CC signaling pathways by PACAP increasing expression of genes encoding neuropeptides (NPs), additional mediators, catecholamine biosynthetic enzymes, and adhesion factors and connexins that increase cell-cell communication among CCs and amplify CA, neuropeptide, and chromogranin output in response to stress; c. NP (neuropeptide) release from CCs has autocrine effects on CA secretion from CCs themselves (e.g. catestatin, substance P, and others), activation of sensory neurons (e.g. BAM22P, acting on specific receptors expressed in sensory nerves), and modulation of CORT secretion from the adrenal cortex (galanin, VIP, and other peptides), as well as hormonal effects on distant organs; d. CA release from CCs into the general circulation, and affecting metabolism, heart rate, blood pressure, and immune cell mobilization; e. *Cytokines* released as blood-borne molecules or locally from circulating monocyte macrophages act as inhibitors of CORT secretion in the adrenal cortex, and as modulators of peptide secretion in adrenal cortex via receptors on CCs themselves; f. Sensory inputs to adrenal medulla sense CC secretory activity via release of BAM-22P, for which sensory neurons express specific receptors. Also depicted are the targets of glucocorticoid (CORT) release from the adrenal cortex at the pituitary g and immune system g′, the latter decreasing in turn cytokine secretion, which affects adrenomedullary function during stress. For a further explication of the figure, see the text.

conditions. Paracrine/autocrine regulation, discussed above, is one way in which the activity of individual cells can be aggregated and modulated. This autocrine/paracrine regulatory concept may explain the roles of several of the peptide hormones produced by and released from the adrenal medulla (see previous section), in particular, those that are released at concentrations too low, relative to their potencies, to be active at distant receptors.

A second mode of regulating the collective secretory response of cells within an endocrine organ involves altered cellular adhesion, through the formation of gap junctions among secretory cells themselves (Figure 12). Gap junctions lower the resistance between adjacent cells through physical connections between them. This occurs, at the molecular level, through the dynamic expression of connexins, proteins that form hexameric hemichannels to promote the spread of electrical excitability. Connexins are expressed by rat adrenal CCs (433) and are regulated *in vivo* by changes in splanchnic nerve activity in response to stress (see Ref. 133 for a comprehensive review). It was initially observed that cellular resistances of isolated CCs in primary culture are greater than those of CCs in intact adrenal glands, and this difference inferred to exist due to loss of gap junctions in dissociated cells (120, 433). A series of *in vivo* experiments assessed changes in gap-junction formation in the adrenal medulla *in vivo* as a function of cold stress (summarized in Ref. 261). Rat adrenomedullary slices examined before and after five days of cold stress (134) showed morphological remodeling of both synapses onto CCs and CC cell-cell borders; increased dye permeation between CCs; and increased electrical coupling between CCs after depolarization of single cells. Finally, application of a several-day stress paradigm *in vivo* caused a noticeable increase in CA secretion after an applied electrical stimulation that was attenuated by pharmacological inhibition of gap-junction formation. Further investigation of the detailed biochemical constitution of gap junctions in the adrenal medulla, and the modulation of gap-junction formation in concert with altered secretory function after stress, has been reported (133, 162). Thus, in addition to shifts between the balance of cholinergic and PACAPergic neurotransmission from rest to stress, physical reorganization of the gland itself anticipates further episodes of stress. The actual first messengers mediating this adaptive response, whether the neurotransmitters ACh and/or PACAP, or autocrine factors released from the CCs in response to stress transduction, are as yet unidentified.

The role of gap junctions in adrenomedullary function may well apply to other endocrine organs (219). It is worth noting that the stress stimuli so far selected for the study of gap-junction-driven plasticity of the adrenal medulla are not among the most "selective" for that organ (252). Cold stress, for example, activates NE secretion rather more than EP secretion, suggesting that its major effect is on postganglionic sympathetic neuronal activity rather than CC activation. It remains to be seen if principal ganglion cells of the SNS respond to stress as the adrenal medulla does. An additional unresolved issue is whether PACAP, or ACh, or both are the principal regulator(s) of either type of adrenomedullary stress-induced plasticity. Stress also regulates CC responsiveness through alteration of other components of the CC. Two important examples are the recruitment of T-type ($Ca_V3.2$) Ca^{2+} channels during chronic hypoxia and β-AR stimulation of cultured rat CCs that cause a pronounced reduction of the threshold of CA release associated with the low threshold of activation of newly recruited Ca^{2+} channels (104, 479) (see below). It is also noteworthy that CCs from mice previously stressed by exposure to rats express a high density of T-type channels as determined by Ca^{2+} current patch-clamp studies (Emilio Carbone, Chiara Calorio, and Daniela Gavello, unpublished observation).

Adrenomedullary function during inflammatory responses

Inflammatory responses involve multiple organs and are mediated largely by cytokines that act hormonally on virtually all tissues via the circulation, as well as locally through the mobile and ubiquitous cytokine-secreting cells of the immune system, which can migrate to various locations during and after infection. Lipopolysaccharide and cytokine receptors have been identified functionally and biochemically on CCs, suggesting a role for the adrenal medulla in responding to inflammation, and potentially coordinating various phases of the immune response (Figures 12 and 13). In fact, this signaling system may hold the key to explaining how stress and immune function mutually modify one another, although definitive experiments in this direction remain to be reported (82, 171).

Two inflammatory cytokines, interleukin type 1 (IL-1) and tumor necrosis factor-alpha (TNF-α), have been shown to regulate CC neuropeptide expression, increasing expression of VIP and decreasing that of met-enkephalin in bovine CCs in primary culture. These cytokines also amplify the effects of cAMP on VIP and substance P biosynthesis (211). The TNF-α receptor is expressed in the bovine adrenal medulla *in vivo* (4, 5), and TNF-α regulates gene transcription and elevates production, of both galanin and secretogranin II (SgII) (5). Bunn and colleagues have postulated a role for TNF-α in VIP biosynthesis and TH induction, based on inflammation-induced elevation in mRNA encoding the neuropeptide prohormone and the TH protein, in the rodent adrenal medulla *in vivo* (82, 171). Additional studies support a physiological role for cytokine regulation of adrenomedullary peptide production, in particular in counter-regulation of inflammation. Thus, cytokine-induced production of galanin (4) may counter-regulate cytokine actions elsewhere in the body via enhancement of glucocorticoid production in the adrenal cortex (483) (see Figure 13). IL-1 and TNF (82), themselves inflammatory cytokines, increase the production of IL-6 mRNA in CCs. As IL-6 has anti-inflammatory properties, its production by the adrenal medulla may also function as a counter-regulator of excess cytokine action associated with the pathogenesis of sepsis.

Interactions between cytokines and CC neuropeptides may also be more or less pronounced in the presence of PACAP and CC autocoids (Figure 13), thus linking anti-inflammatory mechanisms to stress and potentially allowing a better understanding of multiorgan involvement in pathophysiological states including inflammation and hypertension (88).

GABAergic regulation of CA release

Excessive response to stress can be harmful. Therefore, adequate control of CA secretion by CCs is essential for normal physiological function and appropriate stress response. Substances secreted by CCs can either augment or decrease CA exocytosis. Receptors for ATP (P2Y receptors), CA (α-adrenergic receptors), and enkephalin (μ-opioid receptors) coupled to Gi-type G-proteins inhibit Ca_V channels and CA release (148) (see also *Ca^{2+} channel-secretion coupling* above). Conversely, D1 dopamine and β-adrenergic receptors augment CA release by increasing Ca^{2+} influx through L-type Ca^{2+} channels or by phosphorylating components of the exocytosis apparatus (30, 100). A regulatory mechanism mediated by gamma-aminobutyric acid (GABA, the main inhibitory neurotransmitter of the CNS) was also described in the adrenal gland (493).

GABA inhibition in the CNS is mediated by ionotropic $GABA_A$ receptors ($GABA_A$-Rs), permeable to Cl^- ions and metabotropic G-protein-coupled $GABA_B$ receptors, which control cellular excitability by regulating Ca^{2+} and K^+ ion channels (22, 71, 75). When GABA (or the $GABA_A$-R agonist muscimol) is injected intravenously, heart rate and blood pressure increase (75). These cardiovascular actions are prevented by adrenalectomy or a $GABA_A$-Rs antagonist, suggesting stimulation of CA secretion by $GABA_A$-Rs. In the isolated adrenal gland, muscimol increases baseline CA release but reduces synaptically evoked CA secretion (317). This paradoxical effect reflects the "dual action" of $GABA_A$-R activation (273, 439). GABA is stored in dense core granules (274) and it is likely released together with CA, ATP, and opioids in response to physiological stimuli (493). Functional tests with $GABA_A$-R antagonists indicate that GABA is present in the milieu of adrenal medulla slices (14, 273).

Acute application of GABA or muscimol to CCs in culture causes membrane potential depolarization, AP firing, opening of Cav channels, and a transient $[Ca^{2+}]_i$ rise that initiates CA exocytosis (87, 240, 317, 493, 513). GABA-induced adrenal CA secretion is likely due to this excitatory mechanism. Conversely, $GABA_A$-Rs tonically inhibits spontaneous cholinergic transmission (14) and shunts CC membrane electrical resistance, weakening synaptic excitation and impairing AP firing (13, 14, 87, 350). These effects explain the GABA inhibition of synaptically evoked CA release (317).

In neurons, intracellular chloride concentration ($[Cl^-]_i$) results from the interplay between Cl^- accumulation by the $Na^+/K^+/2Cl^-$ cotransporter NKCC1 and Cl^- extrusion by the cation-chloride cotransporter KCC2. Immature neurons display excitatory responses to GABA (55) because of Cl^- efflux due to a high $[Cl^-]_i$, resulting from a greater functionality of NKCC1 (Figure 14). Conversely, in mature neurons, the GABA response is inhibitory because $[Cl^-]_i$ is low due to a dominant activity of KCC2, and Cl^- enters the cell ((336); Figure 14B). In rat adrenal CCs ~44% of $GABA_A$-Rs-mediated response comprises depolarization and $[Ca^{2+}]_i$ elevation (Figure 14C), while in ~26% it includes hyperpolarization and $[Ca^{2+}]_i$ drop (Figure 14D) (13, 14); the remaining CCs are unresponsive. Since muscimol-induced $[Ca^{2+}]_i$ rises are not inhibited by bumetanide (13), NKCC1 is probably not responsible for Cl^- accumulation in rat CCs. This role could be played by the anion-exchanger AE3 or by Pendrin, a member of the SLC26A family of Cl^-/HCO_3^- exchangers that is expressed in adrenal CCs and can modulate CA release (373). Pendrin would be most active in CCs that respond to GABA with membrane depolarization and $[Ca^{2+}]_i$ rise (Figure 14C). The dynamic reciprocal regulation of AE3/Pendrin and KCC2 underlies the variance in $[Cl^-]_i$. It is plausible that the proportion of CCs responding to GABA with excitation or inhibition varies depending on how $[Cl^-]_i$ is controlled (333).

Experiments in isolated rat adrenal gland suggest that GABA regulates CA secretion differently depending on the functional state: Under nonstressful conditions, the activation of $GABA_A$-Rs by endogenous GABA inhibits cholinergic transmission and reduces CC excitability (14), thus preventing excessive CA release. During intense stress, strong synaptic stimulation initially causes a vigorous CA release, which then declines (240). Activation of postsynaptic $GABA_A$-R by released GABA can then depolarize CCs and maintain CA exocytosis even under acute stress. These findings emphasize the importance of GABAergic regulation as another CA secretion controlling agent.

The Stimulus-Secretion Coupling of the Adrenal Medulla and CCs in Disease

A role of adrenal CCs in essential hypertension?

Essential hypertension, the most common manifestation of high blood pressure, is also the most insidious since it leads to cardiac hypertrophy, congestive heart failure, stroke, and retina and kidney damage. It has several possible causes, but an augmented sympathetic tone has been implied in many studies (23, 212). Higher levels of plasma CAs resulting from increased release from sympathetic synaptic terminals and adrenal CCs is a common finding in essential hypertension (147, 251). In the spontaneously hypertensive rat (SHR), an animal model (488) widely used to investigate hypertension, blood pressure rises above 150 mm Hg at 6 to 9 weeks of age, reaching ~200 mm Hg by 15 weeks (376). At 45 weeks of age, SHRs develop cardiac hypertrophy and heart failure (137). Chemical sympathectomy of newborn SHRs delays the onset of hypertension, and when this procedure is combined with demedullation (bilateral removal of the adrenal medulla), adult SHRs become normotensive

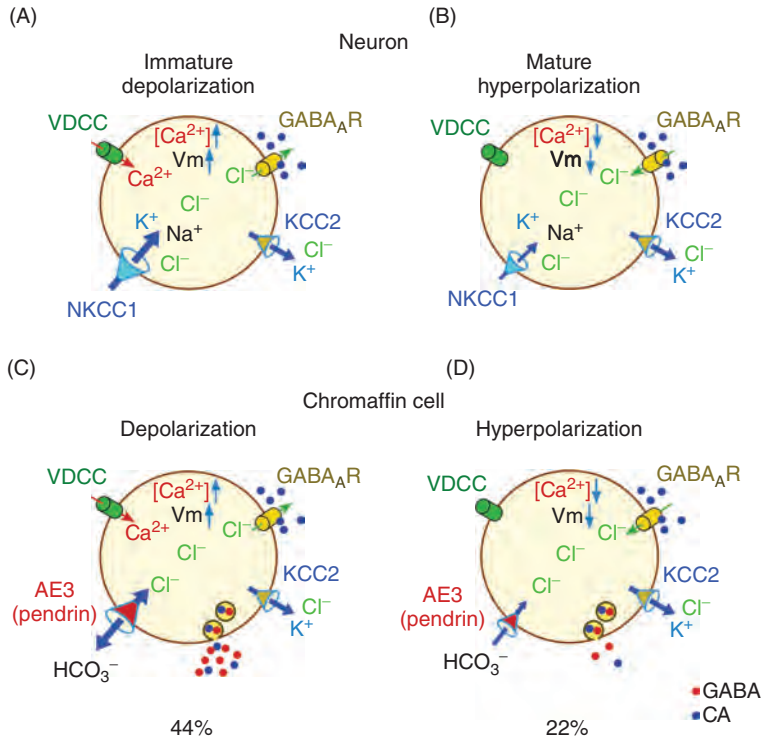

Figure 14 Divergent responses of rat CCs to $GABA_A$ receptor activation. (A) GABA response is excitatory in immature neurons because of a greater functionality of NKCC1. (B) In mature neurons, GABA response is inhibitory because of the dominant activity of the KCC2. (C) $GABA_A$-Rs-mediated response is depolarizing with $[Ca^{2+}]_i$ elevation in ~44% of rat adrenal CCs. (D) in ~26% of CCs, GABA response is hyperpolarizing and causes $[Ca^{2+}]_i$ drop. The scheme also represents the anion-exchanger AE3 (pendrin), which accumulates Cl^- in exchange for intracellular $HCO3^-$ and participates in Cl^- transport into CCs as a replacement for NKCC1. VDDC: voltage-dependent Ca^{2+} channel.

(376). In fact, in young SHR, both EPI and NE plasma levels are elevated compared to age-matched normotensive Wistar-Kyoto rats (WKY) (496), and isolated adrenal glands from SHR secrete more CA than those from normotensive rats in response to depolarizing agents (ACh or high K^+) (385). In cultured CCs, the CA secretion (cumulative charge) measured with single-cell amperometry (see the section titled "Measuring exocytosis") is 2.3-fold higher and the number of spikes 2.4-fold larger in SHR versus WKY CCs (65, 445). Likewise, massive intracellular Ca^{2+} release from the ER or mitochondria triggers long-lasting bursts of spikes, threefold larger in SHR CCs compared to WKY CCs (444). Among the mechanisms suggested to explain the enhanced CA secretion in adult hypertensive SHRs (16-weeks old) are the augmented capacity of the ER Ca^{2+} store due to impaired mitochondrial Ca^{2+} uptake; greater cytosolic and mitochondrial Ca^{2+} transients; larger microdomains of high-$[Ca^{2+}]_i$ at sub-plasmalemmal sites; augmented vesicle pool; and greater quantal size of amperometric events (65, 444–446, 460).

In early hypertensive SHRs (9–12 weeks of age), spontaneous amperometric events are more numerous and of larger mean amplitude in SHR CCs than in WKY. A brief stimulation with high K^+ or caffeine (which causes voltage-gated Ca^{2+} influx or intracellular Ca^{2+} release, respectively) triggers a burst of spikes with greater mean amplitude in SHR CCs. Therefore, CA secretion for both stimuli was approximately twofold higher in SHR CCs (566). Treatment with ryanodine, a specific blocker of RyRs, reduced depolarization-induced CA secretion by 77% in SHR CCs and 10% in WKY, suggesting a greater contribution of Ca^{2+}-induced Ca^{2+} release to CA exocytosis in SHR CCs (Figure 15). Also, $[Ca^{2+}]_i$ signals elicited by a brief stimulation with high K^+ or caffeine were 3.2- and 2.5-fold larger, respectively (566). Together, these findings implicate an enhancement of CA release in the origin of hypertension in this model in SHR and support the notion that a key mechanism involved in the enhanced secretion of CA at early stage of hypertension is a "gain-of-function" of the RyR, an intracellular Ca^{2+} release channel from the ER.

The hypothesis that SHR CCs could have Ca_V currents of greater magnitude was discarded. Electrophysiological recordings showed that this current is either indistinguishable in both strains (565) or reduced by ~39% in SHR CCs

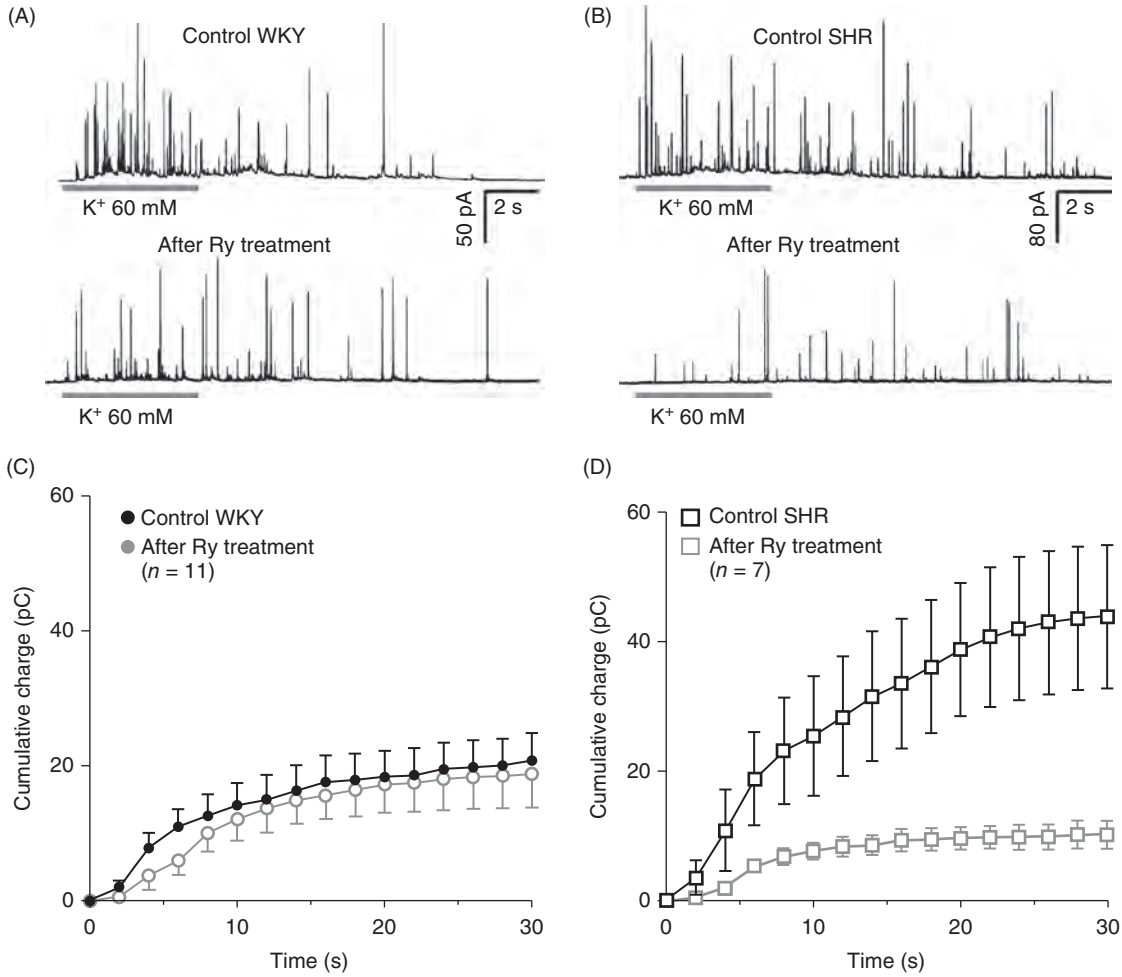

Figure 15 Ryanodine effects on depolarization-induced CA secretion. (A, B) Burst of amperometric spikes elicited by a 5-s-long depolarizing pulse in a WKY (A) and an SHR CCs (B) before (top) and after (bottom) incubation with 10 μM ryanodine. (C, D) Mean cumulative charge in WKY and SHR CCs, respectively, before and after ryanodine treatment. The cumulative charge after RyR blockade was not significantly affected in WKY CCs (20.8 vs. 18.8 pC; $p = 0.274$), but it was drastically reduced in SHR CCs (from 43.9 to 10.1 pC; $p = 0.0001$). The number of cells examined is shown in parentheses. Reused, with permission, from Segura-Chama P, et al., 2015 (566).

compared to WKY (460). A comprehensive analysis revealed that CA hypersecretion in SHR CCs results from the combination of larger depolarization-induced Ca^{2+} transients, more exocytosis events per time unit, and a greater proportion of medium and large amperometric spikes due to a higher CA content per granule (566). A study in prehypertensive SHRs and WKY CCs at 4 weeks of age revealed that all changes found in early hypertensive rats (566) are already present, but to a lesser degree (Peña-del Castillo, JG, in preparation). The cumulative secretion elicited by high K^+ and caffeine is 2- and 1.6-fold larger, respectively, in SHR, compared to WKY CCs. Ryanodine treatment reduces CA secretion by 48% in SHR and by 10% in WKY, and $[Ca^{2+}]_i$ signals elicited by stimulation with either high K^+ or caffeine were 1.4-fold larger in SHC CCs. These data suggest that the "gain-of-function" of the Ca^{2+}-induced Ca^{2+} release mechanism is already present in prehypertensive stages in SHR CCs and that it intensifies with age. It remains to be established to what extent the dysfunctional CA secretion by the adrenal medulla and possibly the SNS are involved in the origin of essential hypertension. Identifying the most likely molecular targets of adrenal and sympathetic hyperfunction in SHR rats leading to hypertension, and their potential dysfunction in human hypertension, is an area in which further advances will have major clinical implications.

Pheochromocytoma

Pheochromocytoma is a tumor arising from CCs in the adrenal medulla and sympathetic paraganglia, which can synthesize and secrete NE, EPI, and, to a lesser extent, DA (21, 617). By acting on their target receptors, these CAs cause significant physiological changes in the body, most often severe hypertension, which can cause devastating cardiovascular and cerebrovascular effects, if untreated (77). Pheochromocytomas are more prevalent than paragangliomas. Yet, the combined

prevalence of these tumors is less than 0.05% in the general population (27, 492). Most pheochromocytomas are benign tumors: the prevalence of malignancy varies between 10% and 15%. In contrast to the normal adrenal medulla, negative feedback of TH on CA synthesis is absent in pheochromocytoma, thus contributing to the uncontrolled and autonomous synthesis of CAs (462). The surgical treatment represents the only modality of ultimate cure, but timely diagnosis and pharmacological treatment is the basis of a successful outcome. Several laboratories have devoted considerable effort to validating markers for pheochromocytoma and especially in distinguishing its benign and malignant forms (378).

While the most common sign of pheochromocytoma is hypertension (90), additional symptoms include episodes of headache, palpitation, anxiety, and sweating related to excess CA secretion (21). The duration of paroxysms varies from a few minutes to 30 min, separated by asymptomatic intervals, from many times per day to a few times per month. Other less well-known symptoms are nausea, vomiting, weight loss, and diabetes mellitus. The secretory profile of pheochromocytoma can be useful in its diagnosis. Extra-adrenal tumors secrete NE and rarely DA (525), while adrenal pheochromocytomas primarily secrete EPI, with or without NE. DA-secreting tumors are rare and occur only in extra-adrenal tumors. Patients with tumors that produce high concentrations of NE are likely to incur sustained hypertension, while patients with elevated levels of EPI often experience paroxysmal and orthostatic hypertension (321). DA-secreting tumors are often asymptomatic (525). Pheochromocytomas can also produce adrenomedullin, vasoactive intestinal polypeptide (VIP), ACTH, NPY, endothelin-1, somatostatin, atrial natriuretic factor, and parathyroid hormone-related peptide. The resulting clinical picture will depend on the combination of increased CA and the amount released of these vasoactive substances (424).

CA metabolism is crucial to protect the organism against excessive CAs. In pheochromocytoma, more than 94% of the metanephrines derive from CA metabolism within tumor cells (195). Production and secretion of metanephrines is continuous and independent from CA secretion. Dopamine is also O-methylated by COMT to 3-methoxytyramine (3-MT), which is also continuously released from the tumor (195, 197). While free metanephrines are excreted in urine, the sulfate-conjugated metanephrines (194) represent 30-fold higher levels than free metanephrines, and are the principal form in which they are finally eliminated in the urine. Some of these metanephrines are oxidized to 3-methoxy-4-hydroxyphenylglycol (MHPG) (194). Both DHPG and MHPG are oxidized in the liver to vanillylmandelic acid (VMA), the major end product of CA metabolism (196). This unconjugated metabolite, excreted in the urine, has been used for many decades as a marker of the presence of CC tumors. However, VMA has insufficient diagnostic accuracy and has been removed from the diagnostic checklist of CC tumors (378).

It is impossible to predict when and how much CA a particular tumor will release during a secretory episode, but it is known that hypertensive paroxysms can be precipitated by physical activity (exercise and postural change) or tumor manipulation (77, 289). One of the few physiological studies conducted on cultured human pheocromocytoma cells (289) revealed that they express densities and proportions of L, N, and P/Q types of voltage-gated Ca^{2+} channels similar to those of normal human CCs. Nonetheless, the extent of downmodulation of Ca^{2+} currents by ATP and opioids is quite heterogeneous in these cells. The pattern of exocytotic events is also heterogeneous; some cells secrete spontaneously and continuously, while others evoke a normal secretory pattern after a brief pulse of high K^+. Cell heterogeneity suggests that normal CCs coexist with pathological CCs that escape the autocrine/paracrine downmodulation of Ca^{2+} channels and hence, may produce abnormal Ca^{2+} signals and CA hypersecretion. Hyperexcitability of CCs is also likely, given the reported peak of CA secretion often observed during tumor manipulation (288). These alterations could underlie the uncontrolled CA peaks suffered by patients with pheochromocytoma, which are responsible for the typical symptoms produced by this tumor. There is much to be learned about the physiopathology of tumoral CCs. This knowledge will certainly provide a basis for better understanding of the pathogenesis and treatment of this disease.

The molecular mechanism regulating CA release during acute, chronic, and intermittent hypoxia

In mammals, low oxygen pressure (hypoxia) is an environmental stressor that triggers CA release from adrenal CCs, depending on the extent and duration of the hypoxic exposure (97, 332). The acute response is initiated by the O_2-sensitive glomus cells of the carotid body that through the activation of SNS triggers the release of CAs from CCs. Acute hypoxia causes sustained cell depolarization, repetitive firing, Ca^{2+} entry, and CA release (73, 239, 449, 482, 550, 602, 615).

In most animal species, adrenal CCs play a critical role during fetal and perinatal life when sympathetic innervation is absent or immature. CCs possess inborn chemosensitivity to O_2 that allows them to control directly the release of CAs from the adrenal gland under nonneurogenic conditions (567, 578). In CCs of fetal and neonatal rodents, the hypoxia-induced release of CAs plays a key role in setting heart rates and oxygen delivery to the growing tissues (529). This is particularly evident during the transition from intra- to extrauterine life when the fetus experiences episodic asphyxia, and the hypoxia-induced release of CAs helps to regulate the cardiac function through the activation of β-ARs and prepare the lungs for air-breathing (567, 578). As the adrenal gland acquires cholinergic innervation, typically during the seventh to tenth postnatal days in rodents (619), the acute hypoxia-sensing mechanism of CCs is gradually suppressed with the same time course (567, 578). Remarkably, direct O_2-sensitivity is reestablished after adrenal gland denervation (567). How this occurs is not yet fully understood. There is likely a developmental loss of hypoxia chemosensitivity in CCs (343, 450, 534, 613, 614) that can

reemerge after prolonged deprivation of neural input in adult rat adrenal glands. However, there is also evidence that a fraction of CCs intrinsically possess an O_2-sensing mechanism regardless of cholinergic innervation, which is also effective in adult rat CCs (239, 315, 375, 449, 602). This issue, and the remodeling of cell function that occurs in response to chronic and intermittent hypoxia, will be explored and clarified in the following sections.

The role of K^+ channel in O_2-sensing in perinatal and mature CCs

The first cellular studies addressing the K^+ channel types involved in the nonneurogenic mechanisms of the hypoxia-induced secretory response in cultured rat CCs date to the late 1990s (449, 450, 614). It appeared evident that the Ca^{2+}-dependent release of CA was triggered by a hypoxia-induced block of K^+ channels that generated membrane depolarization, cell firing, and Ca^{2+} entry through voltage-gated Ca_V channels (449, 613). Early findings suggested the involvement of BK and K_V channels. In voltage-clamp experiments, acute hypoxia reversibly inhibited both Ca^{2+}-dependent BK currents and voltage-gated K_V currents (449, 602, 615). Later findings also implicated SK (346, 375) and K_{ATP} (Kir6.1, Kir6.2) ATP-sensitive K channels (73, 375, 550, 615). Acute hypoxia clearly inhibited SK channels, while activating K_{ATP} channels, most likely due to the transient reduction of ATP during low O_2. In the case of SK channels, voltage-clamp recordings showed that hypoxia reduced the outward K^+ currents of neonatal rat CCs and apamin largely prevented these effects (375). In the case of K_{ATP} channels, their involvement and upregulation were evident in rat CCs when acute hypoxia was tested in the presence of the K_{ATP} channel blocker glibenclamide. The addition of glibenclamide did not affect K^+ current, but the inhibitory action of acute hypoxia was enhanced (Figure 2a in Ref. 550), suggesting that K_{ATP} channels are upregulated only in response to low O_2. Current-clamp recordings confirmed this view. The hypoxia-induced cell depolarization caused burst firing in the control condition that was further enhanced in the presence of glibenclamide (Table 2) (see Figure 2b in Ref. 550). Apparently, K_{ATP} channels play a protective role in the hypoxia-induced response of CCs. These channels hyperpolarize the cell during hypoxia and have a maximal expression at mid-gestation decreasing toward late gestation, while BK channels show an opposite trend. Thus, the hypoxia-evoked CA release is attenuated at mid-gestation due to high K_{ATP} expression and more hyperpolarized membrane potential, but is facilitated at birth as K_{ATP} expression decreases and BK expression increases (73).

Likely, heteromeric TASK-1/3 channels are also involved in hypoxia-induced CA secretion in CCs. TASK-1/3 channels are highly expressed in rat and mouse CCs (316, 389) and their activity is moderately reduced (30%–40% inhibition) by acute hypoxia (351). Given the key role that these channels play in setting the resting potential of rat and mouse CCs, it is likely that the hypoxia-evoked reduction of their resting current is sufficient to induce cell depolarization, burst firing, Ca^{2+} entry, and CA release during acute hypoxia. In conclusion, it seems that, although to different extents, nearly all K^+ channels expressed in mammalian CCs are involved in O_2-sensing, suggesting a common mechanism acting on a protein domain shared by all of the K^+ channels of CCs.

Concerning the O_2-sensing mechanism, significant progress has been made in the past decade to understand the downstream events in the signal transduction cascade regulating the hypoxia-evoked response in CCs, nicely described in recent reviews (401, 482). Briefly, there is strong support for the involvement of complexes I and IV of the mitochondrial electron transport chain (ETC) coupled to the alteration of reactive oxygen species (ROS) (344, 450). Recently, it has been proposed that loss of the mitochondrial subunit *Ndufs2* of complex I, which encodes a protein that participates in ubiquinone binding, is critical for the O_2-sensing mechanism in glomus cells and adrenal CCs (223). An important role is also played by the cytochrome c oxidase subunit IV isoform 2 (*Cox4i2*) and the NADH dehydrogenase (ubiquinone)1 alpha subcomplex, 4-like2 (*Ndufa4l2*) (238). Unresolved and controversial issues still exist concerning the role of ROS generated by complex I in the O_2 signaling pathway. It is not clear, for instance, whether acute hypoxia induces an *increase* (223) or a *decrease* in ROS (238) and how ROS interact with K^+ channels. Further studies will clarify this issue.

Ca_V channel types responsible for hypoxia-induced release of CAs at embryo and perinatal life CCs and their roles

Ca_V channels have a key role in the hypoxia-evoked response of neonatal CCs (see Refs. 482 and 495 for recent reviews). They convert the hypoxia-induced mild depolarization (73, 550) and associated repetitive firing into Ca^{2+} influx that drives vesicle fusion and release of CAs (224, 550, 602). Thus, the question is: which Ca^{2+} channel types are expressed in neonatal CCs and how they contribute to the release of CAs. As nifedipine strongly attenuates the response of neonatal CCs to acute hypoxia, L-type channels would appear to be critical for the regulation of the hypoxia-induced release of CAs (1, 602, 614). Neonatal CCs of rats, mice, and sheep express different percentages of the same Cav channels expressed in adult CCs (L, N, and P/Q) (20, 73, 224, 379, 495) with relative percentages similar to those found in adult CCs (240, 417), except for a net increase in expression of Cav3.2 (T-type) channels in adults (73, 345, 379). T-type channels are typically upregulated in adult CCs under stressful conditions (107, 298, 368, 479), including chronic (103) and intermittent hypoxia (584) (see below and Table 1 in Ref. 417).

Concerning the specific role of Ca_V channel subtypes on the quantal release of CAs measured with carbon-fiber microelectrodes on embryonic and neonatal CCs, two reports indicate the involvement of L-, N-, P/Q-, and T-type channels that contribute differently to the acute hypoxia-evoked response (417). In one case (224), exposure of cultured rat embryo

CCs to 1 min hypoxia elicits transient bursts of amperometric secretory spikes followed by dispersed spikes during the period of O_2 deprivation. This bulk response is blocked 85% by nimodipine and 35% by combined ω-conotoxin GVIA and ω-agatoxin IVA, suggesting that the acute hypoxic response in early life is initially controlled by both Cav1 (L) and Ca_V2 (N- and P/Q-type) channels. However, due to the fast inactivation of $Ca_V2.1$ (P/Q-type) and Ca_V 2.2 (N-type) channels, their contribution is blunted after a few seconds so that the slowly inactivating $Ca_V1.3$ L-type channels remain the main ones responsible for the hypoxia response. In the second case (379), recording of secretory events with amperometry performed in neonate rat adrenal slices reveals a pronounced spontaneous generation of spike events. Acute hypoxia increases the frequency of spikes, and the hypoxia-induced response is triggered by Ca^{2+}-influx through T-type ($Ca_V3.2$) channels, giving rise to what is commonly indicated as the "low-threshold exocytosis" that also occurs in adult rat CCs exposed to chronic cAMP (110, 479) or chronic hypoxia (104, 107). Interestingly, T-type channel expression, as well as CC responsiveness to hypoxia decreases with postnatal maturation, and adrenal medulla denervation restores the sensitivity to hypoxia in parallel with the recruitment of T-type channels.

Ion channel remodeling in CCs following chronic and intermittent hypoxia

Exposure to chronic hypoxia, as it occurs in patients with chronic pulmonary obstructive disease causes elevated sympathetic activity, increased circulating CAs, and hypertension (432). Recent studies have shown that exposure to sustained or chronic hypoxia *in vivo* and in cultured cells leads to a functional remodeling of CCs excitability and CA secretion (89), and this may occur regardless of the increased sympathetic activity (104, 160). In this regard, exposure of cultured adult rat CCs to chronic hypoxia (3% O_2 for 12–18 h) causes a hypoxia-inducible factor (HIF)-dependent upregulation of $Ca_V3.2$ T-type Ca^{2+} channels that results in enhanced CA secretion during prolonged mild depolarizations (2–10 mM KCl) (104). T-type channels are absent in control normoxic conditions (20% O_2), and high-threshold Ca^{2+} currents (L, N, P/Q, and R) are insensitive to low O_2, suggesting that the hypoxia-induced recruitment of T-type channels is the only Ca^{2+} source that during chronic hypoxia sustains vesicle secretion at "low-threshold" voltages. This unique channel remodeling is similar to that occurring with another stressor stimuli (417). Interestingly, an HIF-2α-dependent increased expression of $Ca_V3.2$ T-type channel activity is also reported in PC12 cells following exposure to chronic hypoxia (160).

Chronic hypoxia also causes an upregulation of the brain-derived neurotrophic factor (BDNF)-TrkBs signaling pathway in CCs that leads to an increased voltage-gated Ca^{2+} entry and CA secretion (562). TrkBs are usually expressed in CCs and are upregulated during chronic hypoxia. Addition of BDNF causes increased burst firing, elevation of intracellular Ca^{2+}, and enhancement of CA release. Addition of the selective blocker of T-type Ca^{2+} channels TTA-P2 attenuates the BDNF-induced response, suggesting a key role of T-type channels in the upregulation of the Ca^{2+}-dependent CC response during chronic hypoxia. Since chronic hypoxia and stressors in general cause increased levels of circulating plasma BDNF (278), the facilitation of the BDNF-TrkB signaling pathway provides an alternative non-neurogenic mechanism that may contribute to the enhanced CA release during chronic hypoxia.

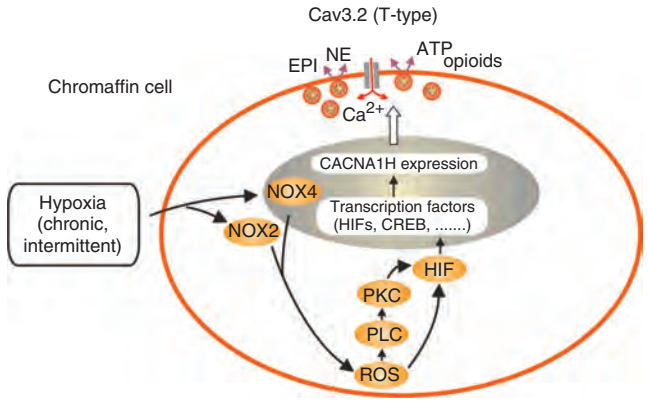

Figure 16 Cell signaling pathways leading to CACNA1H gene expression and Cav3.2 channels recruitment during chronic or intermittent hypoxia. Schematic pathway of the activation of transcription factors (HIF, CREB, etc.) and CACNA1H gene expression through a NOX, ROS, PLC, and PKC cascade leading to Cav3.2 channels recruitment during chronic/intermittent hypoxia. Adapted, with permission, from Mahapatra S, et al., 2012 (417).

Recurrent apnea with chronic intermittent hypoxia occurs in patients with sleep-disordered breathing and is associated with an increased sympathetic activity, enhanced levels of circulating CAs, and increased risk to develop hypertension and stroke (572). In adult rats, exposure to intermittent hypoxia leads to the potentiation of CA secretion from CCs during acute hypoxia. The mechanism involves a PKC-dependent increase of the RRP of SGs and an HIF-2α-dependent cell function remodeling (521). A similar potentiation of CA secretion in response to acute hypoxia is evident in neonatal CCs after exposure to intermittent hypoxia. The effect is associated with an increase of voltage-gated Ca^{2+} entry and intracellular Ca^{2+} stores (585) driven by a NOX-ROS-PLC-PKC signaling pathway, culminating in HIF-dependent upregulation of NADPH oxidase. The result is an increased expression of both $Ca_V3.1$ and $Ca_V3.2$ T-type channels and RyR_2 and RyR_3 (Figure 16).

Altered CC exocytosis by mutated proteins linked to human neurodegenerative diseases

A limited but increasing number of studies support the hypothesis that altered synaptic neurotransmitter release in various brain nuclei during the progression of neurodegenerative diseases is paralleled by changes in secretion in the sympathoadrenal axis (157). Below, we address how

proteins associated with neurodegeneration in various neurological diseases, including Parkinson's, Huntington's, and Alzheimer's diseases, autism, and amyolateral sclerosis, may function, or contribute to dysfunction, including the stages of exocytotic CA release from CCs (for complete details, see the section titled "Measuring exocytosis").

Altered CA exocytosis by the expression of proteins associated with neurodegenerative diseases

α-*Synuclein* The protein α-synuclein is located at presynaptic nerve terminals under physiological conditions. However, duplication and triplications of the WT human α-synuclein gene are present in familial forms of Parkinson's disease (PD) and dementia with Lewy bodies (577). Diminution of spontaneous synaptic responses (563), and of neurotransmitter release due to a reduction in size of the vesicle recycling pool (475), occurs in neurons overexpressing human α-synuclein. Also, this overexpression leads to synaptic dysfunction and diminished exocytosis in the striatum (258, 571). Pathology associated with α-synuclein has also been found in the adrenal medulla of PD patients and mouse CCs endogenously expressing the protein (234). Furthermore, the overexpression of α-synuclein in mouse CCs decreases CA release by acting at a late exocytotic step (372) that is associated with an acceleration of exocytosis by promoting fusion pore dilation (399). Thus, it seems that striatal synaptic pathology linked to α-synuclein also exists in adrenal medullary CCs, causing altered fusion pore kinetics and decreased exocytosis.

Huntingtin Expansion of CAG trinucleotide repeats (CAG repeats) in the N-terminal part of the huntingtin gene is the main pathological feature of HD. Huntingtin-associated protein 1 (HAP1) is the first interacting partner of huntingtin, and the degree of binding correlates with the length of the polyglutamine (CAG) repeats and primarily localizes to synaptic vesicles (382). Peripherally, HAP1 also localizes in secretory vesicles of endocrine cells, including adrenal medullary CCs (177, 384). This generated the hypothesis that HAP1 could contribute to the regulation of exocytosis. Adrenal CCs from mice with the HAP1 gene deleted discharged fewer amperometric secretory spikes and total secretion was decreased, upon stimulation with high K^+; this correlated well with a smaller RRP and a smaller fraction of docked vesicles, indicating that HAP1 reduces full fusion exocytosis by affecting vesicle docking and control of fusion pore stabilization (414). HAP1 also decreases endocytosis by interacting with some proteins of the exocytotic machine and binding to clathrin (415).

Altered excitability and exocytosis in mouse models of neurodegenerative diseases

The APP/PS1 mouse model of Alzheimer's disease

Senile plaques of amyloid-beta (Aβ) and neurofibrillary tangles due to tau hyperphosphorylation are the pathogenic hallmarks of Alzheimer's disease (AD) (275). Synaptic deficits correlate with this disease (568). Presenilin 1 (PS1) is the catalytic subunit of the multimolecular complex ϒ-secretase; PS1 contributes to the regulation of Ca^{2+} movements from the ER (474) and of neurotransmitter release (688). Mutations in the amyloid precursor protein (APP) and PS1 have been linked to early onset AD and to alterations of Ca^{2+} signaling and synaptic transmission. *APP/PS1* mice carry the Swedish mutation and the human PS1 mutation A246E (66). These mice develop an AD-like disease consisting of early Aβ plaques (66), diminished long-term potentiation (266), impairment of hippocampal synaptic transmission (524), and decreased synaptic plasticity (246). About 60% of amperometric secretory spikes generated with K^+ depolarizing pulses in CCs are preceded by an observable "foot." In aged mice, four of the characteristics of single exocytotic events were substantially smaller in *APP/PS1* mice with respect to wild-type mice, namely, peak current (Imax; −30%), decay time (−40%), $t_{1/2}$ (−45%), and quantal size (−50%). Thus, the fusion pore stabilization, expansion, and closure are faster in *APP/PS1* mice, but CA secretion is less. Although these mice exhibited brain Aβ deposition, Aβ pathology was not observed in their adrenal medullary tissue (156).

The SOD1^{G93A} mouse model of amyotrophic lateral sclerosis

Selective loss of motor neurons in amyotrophic lateral sclerosis (ALS) patients leads to paralysis, respiratory insufficiency, and death 3 to 5 years after diagnosis (546). Around 10% of patients have a mutation of glycine to alanine at codon 93 at Cu^{2+}/Zn^{2+}-dependent superoxide dismutase 1 (SOD1^{G93A}). In model mice, this mutation produces ALS paralytic symptoms at postnatal day 90, mimicking the human disease onset (267). Pathogenic features of ALS include augmented glutamate release (141, 339, 607), disturbed Ca^{2+} handling, overproduction of free radicals, and motor neuron death by apoptosis (651).

In adrenal CCs from SOD1^{G93A} mice at ages P90-P120, ACh elicited a 47% higher exocytosis burst secretion compared to WT mice. The kinetic analysis of single-vesicle amperometric events revealed notable differences in SOD1^{G93A} CCs. There was a 36% lower rise rate and 61% slower decay with 55% wider half-width and 52% higher quantal size, giving rise to single-vesicle exocytotic spikes with a slower release rate but greater CA release (92).

The R6/2 and R6/1 mouse models of Huntington's disease

HD is an autosomal dominant neurodegenerative disease with clinical symptoms of hyperkinetic involuntary movements, progressive dementia, aggressiveness, and paranoid psychosis. The disease is associated with mutated huntingtin, consisting of an anomalous expansion of CAG repeats giving rise to extended polyglutamine stretch and resulting in the formation of misfolded huntingtin aggregates that accumulate in the nucleus and the cytoplasm. These pathological features

are associated with neuronal loss in the caudate nucleus and putamen, in cortical layers III, IV, and VI and the lateral tuberal nucleus of the hypothalamus (365, 653). Mutated huntingtin aggregates and neuronal death are the two relevant markers of human HD that have been modeled in mice. For instance, transgenic mice R6/1 and R6/2 express the human huntingtin gene with, respectively, around 115 and 150 CAG repeats (425). In comparison with other HD mouse models, the R6/2 is the one that develops widespread huntingtin inclusions in the brain and early phenotypic symptoms (383). The R6/1 model reproduces several features of HD in older animals (272, 547, 548). Synaptic dysfunction and altered neurotransmitter release have been found in these HD mice models. For instance, electrically evoked dopamine release is attenuated in brain slices of 6-week-old R6/2 mice (327). The same group found that K^+ stimulation triggered a secretory response with similar spike number but lower vesicle quantal size (328) in CCs of R6/2 mice 3-months old. In a recent study performed in R6/1 mice, several alterations in CCs were reported; some of them were already present in 2-month-old mice at a phenotypic pre-disease stage, but they were more pronounced in 7-month-old mice when motor deficits were already established. CCs from R6/1 mice exhibited the following features: (i) mutated huntingtin overexpression as nuclear aggregates; (ii) smaller CC size with decreased dopamine-β-hydroxylase, indicating a decreased number of chromaffin SG; (iii) reduced adrenal medulla CA content; (iv) reduced peak Na_V currents; (v) membrane hyperpolarization and decreased ACh-evoked APs; (vi) diminished $[Ca^{2+}]_c$ transients with faster Ca^{2+} clearance; (vii) decreased quantal secretion with smaller single-vesicle quantal size; and (viiii) faster kinetics of the exocytotic fusion pore, pore expansion, and closure. These data suggest that the primary event in these alterations is the deposition of mutated huntingtin in the nucleus of adrenal CCs of R6/1 mice that could be responsible for less Na_V channel expression and function, giving rise to decreased cell excitability, altered Ca^{2+} handling and exocytosis, and eventually, cell damage and loss of CCs. These data suggest that in HD, the sympathoadrenal axis, which is tightly controlled by cortical neurons via hypothalamus, brain stem, and spinal cord is also significantly affected, predicting dysfunctional stress responses in HD patients (435).

The autistic TS2-neo mouse model carrying the G406R missense mutation on Cav1.2 channel

Timothy syndrome (TS) is a rare multiorgan channelopathy characterized by cardiac arrhythmias, long QTs, immune deficiencies, and autism spectrum disorder (ASD) (586, 587). TS is associated with a *de novo* single point mutation in the pore-forming subunit of $Ca_V1.2$ L-type Ca^{2+} channels (*CACNA1C*) and exists in two major forms (TS1 and TS2), depending on whether the point mutation appears on exon 8a (587) or exon 8 (586). The two exons code for the IS6 helix of $Ca_V1.2$ channel controlling the voltage-dependence of activation and inactivation. In the TS2, one mutation occurs at gly406 (G406R) within exon 8 that is highly expressed in the brain and the heart (80%) and to a lesser degree in the adrenal glands (586). The mutation causes reduced channel inactivation and shifts the voltage dependence of activation toward more negative potentials, thus causing increased Ca^{2+} influx during rest and cell activity. TS2 patients with the G406R mutation exhibit ASD-type behaviors (586).

The recent availability of the autistic TS2-neo mouse (41) made it possible to study the origins of neuronal firing and Ca^{2+} signaling mistuning that might generate autism. CCs possess high densities of L-type Cav1.2 channels (46, 426, 429) and are thus an excellent cell model to study the role of Cav1.2 channels on AP firing and CA secretion (100, 389). Interest in the effects of the TS2 mutation on CC function is intensified by a recent case report of a 2-month-old TS patient, whose post-mortem autopsy revealed remarkable bilateral adrenal glands dystrophy, possibly caused by the increased intracellular Ca^{2+} associated with the $Ca_V1.2$ channel mutation that occurred mainly in the adrenal medulla (340).

Recently, it has been reported that L-type currents in TS2-neo mouse CCs exhibit slower inactivation, voltage-dependent activation and inactivation shifted toward negative potentials, and large "window" current at rest (91). The increased "window" current is a likely cause of the increased resting Ca^{2+} that lowers the density of functioning Na_V channels, promotes AP switching from tonic to bursting firing mode alters cell morphology and reduces both mitochondrial metabolism and CA secretion. Extended cytoplasmic vacuolization and cell swelling is also observed by high-resolution electron microscopy in intact adrenal glands of TS2-neo mice. The findings of Calorio et al. (91), provide evidence that CCs are an excellent cell model for studying the effects of the Cav1.2 G406R mutation on AP firing and on Ca^{2+} signaling associated with autism.

A hypothesis concerning the alterations undergone by the sympathoadrenal axis in neurodegenerative diseases

Evidence is accumulating to support the hypothesis that some of the pathogenic features occurring in the CNS of patients suffering from certain neurodegenerative disease are also expressed in the sympathoadrenal axis. Those alterations may occur for the following reasons: (i) the sympathoadrenal axis may undergo impaired stress responses imposed by the limitations of body functions associated with neurodegeneration, (ii) "propagation" via cortico-hypothalamic-sympatho-adrenal axis of pathogenic synaptic dysfunctions occurring in the brain, (iii) mutant proteins linked to neurodegenerative diseases are expressed in CCs themselves, altering cell excitability, ion currents, Ca^{2+} signaling, and exocytosis, and (iv) leading to chronic alterations of blood pH, hormones, and their metabolites or hypoxic conditions that may further change CC function (see above). These four pathogenic pathways may ultimately give rise to altered exocytotic release at sympathetic neurons, and of NE and EPI at adrenal CCs, thus leading to poor adaptation to stressful conflicts in patients with neurodegenerative diseases.

Conclusion

Being the amplifying arm of the cortico-hypothalamic-sympatho-adrenal axis during the fight-or-flight response, the study of the physiological aspects of adrenal CCs has fundamental and intrinsic interest. Additionally, due to their accessibility and easy preparation of primary cultures from embryos, neonates, or adult mammals, CCs have been used widely as biological models to study exocytosis in fine detail, both ultrastructurally and molecularly. Ever since 1961 when Douglas and Rubin pioneered the discovery that Ca^{2+} entry was the trigger for ACh-mediated explosive release of CAs from perfused cat adrenal glands, we have learned much about cellular excitability, ion channels, Ca^{2+} signaling, SG pools, exocytosis, and endocytosis, both in normal and in animal models of disease, from the CC.

By now, a quite complete list of ion channels has been identified and characterized in CCs from various mammalian species, including humans. However, although the role of most channels has been defined in physiological processes (i.e. cell excitability, exocytosis, and endocytosis), only a few studies have approached how certain pathological states (i.e. hypoxia, hypertension, neurodegenerative diseases, and diabetes) affect these physiological parameters. It is not surprising that, as part of the sympathoadrenal axis that regulates body homeostasis, the adrenal medullary CCs are affected in various disorders, particularly brain disease. There is, therefore, ample scientific motivation to investigate the alterations undergone by CCs in animal models of disease as well as in humans. Recently, ion currents from CCs have been successfully recorded with automated patch-clamp technology and instrumentation (514). Given their relevance as proven models of CNS neurons, CCs could be a suitable preparation for high-throughput screening for the discovery and development of new drug candidates targeting therapeutically relevant ion channels.

The regulation of the rapid exocytotic release of CAs into the circulation during stress is particularly critical for two reasons: first, EPI is the most powerful secreted molecule of the organism and its release must be adapted to the degree of stress; and second, if extensively released, EPI may give rise to hypertensive crises and cardiac arrhythmias. Regulation of exocytosis has various control steps both centrally through afferent sympathetic output to CCs and at the level of the splanchnic-nerve-CC synapse, and in regulating the firing rate of the CC itself. There are also local regulatory loci, for example the activity of Ca_V channels by neurotransmitters acting on surface receptors on CCs. A second important type of regulation, particularly relevant under conditions of chronic stress occurs intracellularly and rests on the rate of secretory vesicle transport and the refilling of the exocytotic machinery with new vesicles. Future experiments should focus this problem in models closer to physiology, namely, in adrenal slices and *in vivo*. As proteins and ion channels are remodeled in cultures of CCs, efforts should be made to clarify this issue using the more complex preparation of adrenal slices.

The simple and classical view that the adrenal medulla releases CAs under acute and chronic stress in response to ACh release from the splanchnic nerve supported the investigation of the detailed cellular physiology underlying the function of this endocrine tissue for many years, and continues to do so. This view has been vastly expanded over the past 20 years, the adrenal medulla is now viewed as a more complex, and more integrative, stress transducer. Basal secretion, under the influence of ACh, is seen as important to cardiovascular function as well. Additional first messengers besides ACh, including GABA, PACAP, bradykinin, angiotensin, histamine, cytokines, and others, provide regulation of the CC and integration of inputs from the immune as well as the nervous system during stress to produce a complex output, including proteins, peptides, and CAs, that likely affects sensory neurons, and perhaps even the brain, as well as liver, heart, vasculature, and other CA target organs. The secretory products of CCs also have important, yet-to-be-discovered paracrine, autocrine, and hormonal roles, and this is especially true for CgA and its processed peptides including catestatin. The roles of ACh at the splanchnicoadrenomedullary synapse may require reassessment, especially regarding a potential role in modulation of gap junctions, nAChR- and mAChR-mediated gene regulation, and subtle but important regulation of the tempo of PACAP-induced CA release during both acute and chronic stress.

For over half a century, the CC has been a unique model to study basic mechanisms of cell excitability, ion channels, Ca^{2+} signaling, exocytosis, and endocytosis, all linked to basic principles of neuronal communication. We predict that CCs, particularly those of transgenic murine models of disease, and after genetic manipulation of SNARE and other proteins of the secretory machinery will continue to be an invaluable tool to explore those mechanisms with complementary genetic and molecular biology techniques, and with electrophysiological and neuropharmacological approaches. The future of CCs as a neuronal model is assured.

The abbreviations used throughout this review are listed in Table 3.

Table 3 List of Abbreviations

Abbreviation	Definition	Abbreviation	Definition
AADC	Aromatic amino acid decarboxylase	DCRD	Distal C-terminal regulatory domain
AE3	Anion exchanger	EGFP	Enhanced green fluorescent protein
Aβ	Amyloid beta-protein	Egr-1	Early growth response protein 1
AC	Adenylate cyclase	EPI	Epinephrine
ACh	Acetylcholine	EPAC	Exchange protein activated by cAMP
ACTH	*Adrenocorticotropic hormone*	ER	Endoplasmic reticulum
AD	Alzheimer's disease	ERG	Ether-à-go-go-related gene
AHP	Afterhyperpolarization	ERK	Extracellularly regulated kinase
AP	Action potential	GABA	γ-Aminobutyric acid
ALS	Amyotrophic lateral sclerosis	$GABA_A$-R	$GABA_A$ receptor
APP	Amyloid precursor protein	GPCR	G-protein-coupled receptor
AR	Adrenergic receptor	HAP1	Huntingtin-associated protein 1
ASD	Autism spectrum disorder	HCMDs	High calcium microdomains
ATP	Adenosine triphosphate	HD	Huntington's disease
BK	Big-conductance potassium channels	HIF	Hypoxia-inducible factor
BAM22P	Peptide (aa210-231) of proenkephalin-A	Kv	Voltage-gated potassium channels
BDNF	Brain-derived neurotrophic factor	IBMX	3-Isobutyl-1-methylxanthine
β-AR	Beta-adrenergic receptor	IL-1	Interleukin type 1
CAs	Catecholamines	$InsP_3$	Inositol tris-phosphate
Cav	Voltage-gated calcium channels	$InsP_3R$	Inositol tris-phosphate receptor
$[Ca^{2+}]_i$	Intracellular calcium concentration	IRP	Immediately releasable pool
$[Cl^-]_i$	Intracellular chloride concentration	ISI	Interspike interval
CC	Chromaffin cell	K_{ATP}	ATP-sensitive K channel
CDI	Calcium-dependent inactivation	KCC2	Cation-chloride cotransporter
CGRP	Calcitonin gene-related peptide	LDCV	Large dense core vesicles
CGs	Chromaffin granules	L-Dopa	Levorotatory form of dopa, L-3,4-dihydroxyphenylalanine
CgA	Chromogranin A	mAChR	Muscarinic cholinergic receptor
cGMP	Cyclic guanosine monophosphate	MAO	Mono amine oxidase
cAMP	Cyclic adenosine monophosphate	MHPG	3-Methoxy-4-hydroxyphenylglycol
CICR	Calcium-induced calcium release	MAPK	Mitogen-activated protein kinase, also called ERK,
CNS	Central nervous system		extracellular signal-regulated kinase
CPE	Carboxypeptidase processing enzyme	mNCX	Mitochondrial electroneutral Na^+/Ca^{2+} exchanger
COMT	Catechol-*O*-methyltransferase	MICU	Mitochondrial Ca^{2+} uniporter
CREB	cAMP response element-binding protein	MCCs	Mouse chromaffin cells
DA	Dopamine	nAChR	Nicotinic cholinergic receptor
DR1	Dopamine receptor type 1	Nav	Voltage-gated sodium channels
DBH	Dopamine-beta-hydroxylase	NE	Norepinephrine

(*continued*)

Table 3 (*Continued*)

Abbreviation	Definition	Abbreviation	Definition
NCS-1	Neuronal calcium sensor-1	SG	Secretory granule
NCX	Na^+/Ca^{2+} exchanger	SHR	Spontaneously hypertensive rat
NCS	Neuritogenic cAMP sensor	SNARE	Soluble NSF-attachment receptor complex
NKCC	$Na^+/K^+/2Cl^-$ cotransporter	SNS	Sympathetic nervous system
NO	Nitric oxide	Sp1	Specificity protein 1
NOS	NO synthase	SK	Small-conductance potassium channels
NPY	Neuropeptide Y	SOCCs	Store-operated calcium channels
NSF	*N*-Ethylmaleimide-sensitive factor	SOD	Superoxide dismutase
PACAP	Pituitary adenylate cyclase-activating polypeptide	SR	Sarcoplasmic reticulum
PAC1R	PACAP type 1 receptor	SRP	Slow releasable pool of vesicles
PAM	Peptidylglycine alpha-amidating monooxygenase	TEA	Tetraethylammonium
PD	Parkinson's disease	TH	Tyrosine hydroxylase
PDE	Phosphodiesterase	TS	Timothy syndrome
PIP_2	Phosphatidylinositol (4,5)-bisphosphate	TIRFM	Total internal reflection fluorescence microscopy
PKA	Protein kinase A	TNF-α	Tumor necrosis factor-alpha
PKC	Protein kinase C	TrkB	Tyrosine receptor kinase B
PKG	cGMP-dependent protein kinase	TTX	Tetrodotoxin
PLB	Phospholamban	VAMP	Vesicular monoamine transporter
PMCA	Plasma membrane Ca^{2+}-ATPase or Ca^{2+} pump	VAChT	Vesicular acetylcholine transporter
PNMT	Phenylethanolamine-*N*-methyltransferase	VNUT	Vesicular nucleotide transporter
PS1	presenilin 1	VIP	Vasoactive intestinal polypeptide
Rapgef	Rap-activating guanine-nucleotide-exchange factor	V-ATPase	Vesicular proton pump
ROS	Reactive oxygen species	VMA	Vanillylmandelic acid
RP	Reserve pool of vesicles	VMAT	Vesicular monoamine transporter
RRP	Readily releasable pool of vesicles	WT	Wild type
RyR	Ryanodine receptor	WKY	Wistar-Kyoto rats
SERCA	Sarco-endoplasmic reticulum Ca^{2+}-dependent ATPase

Vascular endothelial growth factor (VEGF) has long been connected to the development of tissue lesion following ischemic stroke. Contradictory findings either situate VEGF as a promoter of large infarct volumes or as a potential attenuator of damage due to its well documented neuroprotective capability. The core of this discrepancy mostly lies on the substantial number of pleiotropic functions driven by VEGF. Mechanistically, these effects are activated through several VEGF receptors for which various closely related ligands exist. Here, we tested in an experimental model of stroke how the differential activation of VEGF receptors 1 and 2 would modify functional and histological outcomes in the acute phase post-ischemia. We also assessed whether VEGF-mediated responses would involve the modulation of inflammatory mechanisms and how this trophic factor acted specifically on neuronal receptors. We produced ischemic infarcts in adult rats by transiently occluding the middle cerebral artery and induced the pharmacological inhibition of VEGF receptors by i.c.v. administration of the specific VEGFR2 inhibitor SU1498 and the pan-VEGFR blocker Axitinib. We evaluated the neurological performance of animals at 24 h following stroke and the occurrence of brain infarctions analyzed at the gross metabolic and neuronal viability levels. We also assessed the induction of peripheral pro- and anti-inflammatory cytokines in the cerebrospinal fluid and blood and assessed the polarization of activated microglia. Finally, we studied the direct involvement of cortical neuronal receptors for VEGF with *in vitro* assays of excitotoxic damage. Preferential VEGFR1 activation by the endogenous ligand promotes neuronal protection and prevents the presentation of large volume infarcts that highly correlate with neurological performance, while the concomitant activation of VEGFR2 reduces this effect, even in the presence of exogenous ligand. This process partially involves the polarization of microglia to the state M2. At the cellular level, neurons also responded better to the preferential activation of VEGFR1 when challenged to *N*-methyl-D-aspartate-induced excitotoxicity.

Endogenous activation of VEGFR2 hinders the neuroprotective mechanisms mediated by the activation of VEGFR1. The selective modulation of these concurrent processes might enable the development of therapeutic approaches that target specific VEGFR1-mediated signaling during the acute phase post-stroke.

Keywords: Axitinib, ischemia, MCAO, stroke, SU1498, VEGF, VEGFR1, VEGFR2

INTRODUCTION

The neuroprotective molecular mechanisms that drive endogenous adaptive responses to injury in the central nervous system (CNS) are mostly unknown, and their elucidation would ideally open new avenues for rehabilitation. A very promising process to target therapeutically is driven by vascular endothelial growth factor A (VEGF), which has long been implicated in the regulation of several events that take place following ischemic stroke, the leading cause of acquired disability in the developed world.

VEGF regulates a series of molecular processes that allow tissue to adapt to the conditions that prevail after stroke, such as neurovascular remodeling and repair, neuroprotection, brain plasticity and the recruitment and proliferation of neuronal precursors (Zhang et al., 2000; Ma et al., 2012; Dzietko et al., 2013; Greenberg and Jin, 2013). However, VEGF is also responsible for some damaging processes, such as cerebral edema and exacerbated blood-brain barrier leakage (Eliceiri et al., 1999; van Bruggen et al., 1999; Paul et al., 2001; Weis and Cheresh, 2005; Kim et al., 2018; Wu et al., 2018). Such opposing findings have, thus far, impeded the utilization of VEGF in a clinical setting aimed at alleviating the sequels of ischemic stroke.

VEGF acts by activating tyrosine kinase receptors 1 (VEGFR1, also known as FMS-like tyrosine kinase; Flt1) and 2 (VEGFR2, also known as kinase domain receptor; KRD, and fetal liver kinase 1; Flk-1). Both receptors are structurally closely related, each composed with seven immunoglobulin-like domains on the extracellular portion, a transmembrane motif, and an intracellular tyrosine kinase domain with conserved tyrosine phosphorylation sites (Grassot et al., 2006; Rahimi, 2006; Simons et al., 2016), although the ultimate biological actions driven by these receptors individually are somewhat different. Traditionally, VEGFR2 has been considered the canonical receptor for VEGF (Geiseler and Morland, 2018), and for a very long time, VEGFR1 has been thought to function as a decoy signal that counter-regulates VEGFR2 actions by sequestering the ligand, thus reducing its availability to binding VEGFR2 (Park et al., 1994; Meyer et al., 2006). Also, VEGFR1 is preferably activated by other members of the VEGF family, such as VEGF-B (Olsson et al., 2006).

An open question in all these molecular events is whether VEGF can also modulate the neuroinflammation elicited by ischemia (Geiseler and Morland, 2018). Neuroinflammation is an important component of the pathophysiology of stroke and other neurodegenerative processes where microglia, the resident macrophages of the CNS, play a central role.

Here we studied the mechanisms of VEGF-mediated neuroprotection in the acute phase of stroke using an *in vivo* model produced by the transitory occlusion of the middle cerebral artery in the rat (MCAO). The i.c.v. administration of VEGF in the early phase after stroke results in a significant reduction of infarct volume and increased neuronal survival. We found that if VEGFR1 gets preferably activated when VEGFR2 is inhibited, there is a reduction of infarct volume and edema, and an increase of neuronal survival and neurological outcome. Given the role of VEGFR1 on microglial responses to altered brain homeostasis, the underlying mechanisms of the VEGFR1-mediated protection partially involve also the modulation of the inflammatory response and microglial polarization to a neuroprotector phenotype. These results point toward VEGFR1 as an attractive therapeutic target for stroke.

MATERIALS AND METHODS

Animals

In this study, we used young (1.5 months old; 270–290 g) Wistar rats that were subjected to MCAO as described below. Animals were housed in individual cages in a 12 h light/dark cycle with food and water *ad libitum*. All rats were killed at 24 h during the acute phase post-stroke. All experimental procedures were conducted under the current Mexican law for the use and care of laboratory animals (NOM-062-ZOO-1999) with the approval of the Institutional Animal Care and Use Committee (CICUAL-IFC-LTR93-16).

Study Design

Animals were randomly divided into seven groups with an $n = 10–13$ for MCAO groups and 7 shams. The sample size was calculated *a priori* to detect a medium Cohen's d effect size > 0.3, β power of 0.8 and significance of 0.05. Mortality rate was assumed to be 0.4 based on pilot experiments. These parameters were chosen to reduce the number of animals used. Inclusion criteria in analyzes considered the reduction of blood perfusion below 50% of basal values, which roughly corresponds to the effect of occluding the common carotid artery, no immediate recovery of reperfusion (above 50% baseline values within 3 min), total occlusion time between 90–95 min, absence of subarachnoid or intraparenchymal hemorrhages and survival at 24 h after stroke. This study is limited to assess effects on males.

MCAO

Rats were put under isoflurane anesthesia (5% for induction followed by $\leq$1.5% during surgery) with oxygen as the carrier. Normal ventilation was autonomously maintained. Focal cerebral ischemia was induced with the Longa method (Longa et al., 1989) using a nylon monofilament with a silicone-dipped tip

(403734, Doccol, Sharon, MA, United States) that was inserted in a stump created by cutting the ligated left external carotid artery and intraluminally advanced through the internal carotid artery until it reached and occluded the MCA at its inception in the Circle of Willis. MCA occlusion was kept for 90 min after which the monofilament was removed. Body temperature was maintained at 37°C with a heating pad for the duration of surgery. At the end of the procedure, the skin of the neck was sutured, and rats were returned to their cages. During the entire experimental procedure, the cerebral blood flow (CBF) was monitored in the territory irrigated by MCA with laser-Doppler flowmetry. For this, the parietal skull bone was thinned using a small mototool drill bit (Dremel, Racine, WI, United States) and a probe holder was glued onto it at stereotaxic coordinates (AP −1.5 L +3.5 from Bregma). A laser-Doppler probe (model 407, Perimed, Järfälla, Sweden) was inserted into the holder and connected to a Periflux System 5010 (Perimed). CBF was continuously monitored with an acquisition interval of 0.3 s using the Perisoft software (Perimed).

Administration of VEGF and Pharmacological Inhibitors

VEGF and the VEGFRs inhibitors were administered by intracerebroventricular (i.c.v.) injections in the corresponding animal groups 30 min after intraluminal filament removal, which marked the beginning of reperfusion, with the following stereotaxic coordinates: AP −0.8 and L −1.5 from Bregma and V -4 from dura matter. Injections were performed with graduated glass microcapillary pipettes that were pulled to produce a tip < 50 μm in diameter (McCluskey et al., 2008) at a flux rate of 0.8 μL/min. Because of the non-polar nature of the inhibitors used in this study, we injected a corresponding volume of DMSO in all experimental groups to control for DMSO possible effects. Control sham- and MCAO-operated animals were injected with vehicle solutions consisting of 2 μL DMSO followed by 2 μL 0.1% BSA (4 μL final volume). Recombinant rat VEGF-A_{164} (Sigma) was prepared in a 0.1% BSA at a final concentration of 25 ng/μL, 2 μL VEGF were injected followed by 2 μL DMSO. SU1498 and Axitinib (both from Sigma) were prepared in DMSO at a concentration of 6.4 mM. Two μL of each inhibitor were administered in the corresponding groups followed by 2 μL 0.1% BSA or 25 ng/μL VEGF depending on the experimental condition.

Infarct Volume Calculation

Animals were sedated with sodium pentobarbital and transcardially perfused with 200 mL 0.9% NaCl at 4°C, after which brains were collected and immediately sectioned into seven coronal slices (2 mm thick) that were incubated in 2% 2,3,5-triphenyltetrazolium chloride (TTC) at 37°C for 10 min. Images of sections were digitally acquired with a Lexmark scanner (Lexmark X2650, Lexmark, Canada) using Imaging Studio software (Lexmark, Canada). The infarcted and individual hemisphere areas of each section were measured with a semi-automatized macro routine executed in Fiji (Fiji-ImageJ, version 1.52i, NIH, United States) (Schindelin et al., 2012). Infarct volume was then calculated and corrected for edema with the following formula:

$$IV = \sum_{i=1}^{n} \left[\left(\frac{clHA_i \times IA_i}{ilHA_i} \right) t \right]$$

Where IV is the volume of infarct in mm^3, n is the number of sections, $clHA$ is the area of the contralateral hemisphere in mm^2, IA is the area of the damaged tissue in mm^2, $ilHA$ is the area of ipsilateral hemisphere in mm^2, and t is the thickness of each section in mm.

Post-stroke Neuronal Viability Evaluation

For histological analyses, three rats per group were transcardially perfused with 200 mL ice-cold 0.9% NaCl followed by 250 mL ice-cold 4% paraformaldehyde (PFA). Brains were collected and post-fixed in 4% PFA for 24 h and then cryoprotected in 30% sucrose. Whole PFA-fixed brains were cut into 40 μm thick sections in a cryostat to produce 10 series of consecutive sections that were 400 μm apart. An entire series was mounted on gelatin-coated slides and stained with 1% cresyl violet. Digital images of a section series were acquired in an Olympus IX71 microscope with a 20X magnification using a 12 Megapixel Evolution UVF camera (Media Cybernetics, Buckinghamshire, United Kingdom). Images were processed in Image-Pro Plus 6.0 (Media Cybernetics). Soma diameters and shapes of pyramidal neurons within an area of 250 × 350 μm in layers IV and V of the somatosensory cortex in 3 consecutive sections were analyzed with an automatized macro routine executed in Fiji. Healthy cells were defined by circularity values of 0.47 – 0.88 and area of 30 – 250 μm^2. Neuronal viability is reported as a survival index, which was calculated from each count of ipsilateral live neurons expressed as a proportion of the count in the respective contralateral area. The resulting values were normalized to the pooled indexes of the sham group. This algorithm is calculated with the following formula:

$$SI = p\left(\sum_{1}^{t} \left(\frac{\sum_{i=1}^{n} \left(C_i^{il} / C_i^{cl} \right)}{n} \right)_t \right) \Big/ t\left(\sum_{1}^{p} \left(\frac{\sum_{0=1}^{m} \left(S_o^{il} / S_o^{cl} \right)}{m} \right)_p \right)$$

Where SI is the survival index, C^{il} is the number of live neurons in the ipsilateral side, C^{cl} is the number of live neurons in the respective confraternal side, n is the number of coronal sections analyzed for each brain, t is the number of animals analyzed per experimental group, S^{il} is the number of neurons in the left side of the sham group, S^{cl} is the number of neurons in the right side of the sham group and, m is the number of sections analyzed for each sham brain and p is the number of sham rats. No statistical differences were detected in absolute numbers of live neurons among contralateral sides across experimental groups.

Behavioral Testing

Animals were evaluated with a battery of neurological tests to assess sensorimotor deficits 24 h after stroke. The severity of functional deficits was scored by assessing eight items described in **Table 1** with slight modifications from previous reports (Mattsson et al., 1997; Schallert et al., 2000; Burguete et al., 2006; Zhang et al., 2015). Maximum score (32 total) was assigned to animals without neurological deficits. All evaluations were cross-validated by a trained observer blinded to the experimental treatment that analyzed recorded videos of the tests.

Peripheral Cytokines Determination

Blood samples were obtained by cardiac puncture right before transcardial perfusion to determine circulating cytokine levels 24 h after stroke. Plasma was prepared from blood by adding 50 μL/mL 0.5 M EDTA and samples were stored at −80°C until used. Cytokine detection was carried out with a custom-made rat cytokine/chemokine magnetic bead Milliplex MAP panel (Millipore, Temecula, CA, United States) following the manufacturer instructions. A 96-well plate was used to simultaneously determine the concentrations of IL-1β, IL-4, IL-6, IL-10, IL-12p70, IL-17, TNF-α, CCL11, INFγ, CX3CL1, MIP-1α, and VEGF. The plate was read on a MAGPIX system (EMD Millipore, Darmstadt, Germany). Results were analyzed using the xPONENT software (Luminex, Madison, WI, United States). Standards of 200–16,000 pg/mL were used for generating the corresponding concentration curve of each analyte. Determinations were done in duplicates per biological replicate ($n = 3$).

Cytokine mRNA Expression

Cytokine mRNA levels were determined 24 h after stroke by real-time quantitative PCR (RT-qPCR). For this, 1 mL of blood was combined with 50 μL 0.5 M EDTA and 10 mL of red blood cells lysis buffer (155 mM NH_4Cl, 12 mM $NaCO_3$, 0.1M EDTA, pH 7). Samples were centrifuged at 1,900 × *g* for 8 min at RT in a Sorvall ST8 centrifuge (Thermo Fisher Scientific. Karlsruhe, Germany) to obtain white blood cells pellet. Total RNA was isolated with 5:1 TRIzol (Ambion Life Technologies. Austin, TX, United States)-chloroform by phase separation centrifugation at 12,000 × *g* for 15 min at 4°C. RNA was precipitated in 500 μL isopropanol and washed in 75% ethanol. After air-drying, the pellet was reconstituted in RNAse and DNAse free ultra-pure water (Thermo Scientific). RNA concentration and purity were assessed using OD 260/280 ratios and gel electrophoresis. RT-qPCR was performed with One-step NZYSpeed RT-qPCR Green kit, ROX (nzyTECH, Lisbon, Portugal) according to the manufacturer directions. RT-qPCRs were run in 96-well plates in an Applied Biosystems StepOne RT-qPCR System (Thermo Fisher) with the following parameters: 20 min reverse transcription at 50°C, 2 min cDNA denaturing at 95°C, 40 cycles of 5 s denaturation at 95°C, 30 s annealing/amplification at 61°C. Relative quantification of gene expression was performed using the $2^{-\Delta\Delta C_T}$ method, with glyceraldehyde 3-phosphate dehydrogenase as a reference gene. Melting curve analyzes and gel electrophoresis evaluation of the RT-qPCR products were routinely performed to determine the specificity of the RT-qPCR reaction. Primer information for each gene is contained in **Table 2**.

Immunohistochemistry and Confocal Microscopy

PFA-fixed brain sections containing infarct core and penumbra were blocked with 5% bovine serum albumin in Tris-buffered saline with 0.5% v/v Triton X-100 (TBS-T) and incubated with anti-Iba-1 (1:200; Wako, Richmond, VA, United States) and anti-arginase-1 antibodies (1:200; Invitrogen) for 48 h. Sections were washed three times with TBS followed by 2 h incubation at RT with Alexa Fluor 488-conjugated anti-mouse and Alexa 546-conjugated anti-rabbit antibodies (1:2000 each; Invitrogen, Carlsbad, CA, United States) in TBS. Images were obtained in a Zeiss LSM 800 confocal microscope using a 63X objective. An average of 45 optical slices was obtained every 0.5 μm for each Z-stack.

Cortical Neuronal Cultures

Cortical neuronal cultures were prepared from embryonic day 17 Wistar rats as previously described (Tovar-y-Romo et al., 2012). Briefly, cortices were isolated and trypsinized, and cells were dissociated by trituration in a Ca^{2+} and Mg^{2+} free Hanks' balanced salt solution (Gibco, Carlsbad, CA, United States). Neurons were plated at a density of 1.3×10^5 cells/cm^2 in polyethyleneimine-coated 24-well plates in Neurobasal medium supplemented with B-27 (Gibco) and 1% antibiotic/antimycotic solution (104 U of penicillin G/ml, 10 mg of streptomycin/ml, and 25 μg of amphotericin B/ml) (Sigma). Ten μM cytosine β–D-arabinofuranoside (Sigma) was added on DIV 3 to prevent the proliferation of astrocytes.

Immunofluorescent staining was performed in cells plated on glass coverslips and fixed with 100% methanol for 10 min at −20°C on DIV 7. Neurons were incubated with anti-VEGFR1 or anti-VEGFR2 (1:100 each, LifeSpan Biosciences, Seattle, WA, United States) and anti-microtubule-associated protein 2 (MAP2; 1:100, Sigma) overnight at 4°C. Labeled cells were incubated with Alexa Fluor 546- and Alexa Fluor 488-conjugated antibodies (1:200 each, Life Technologies), for 1 h at RT, after three washes, neurons were incubated with DAPI for 5 min and mounted on glass slides. Cells were imaged with confocal microscopy as described above with a 40X objective. An average of 30 optical slices was obtained every 0.5 μm for each Z-stack.

Cortical Neurons Excitotoxicity Assays

Neuronal cultures were challenged on DIV 11 with 1, 10, or 100 μM NMDA + 1 μM glycine for 24 h to induce excitotoxic damage or neuronal death. Rat recombinant VEGF-A_{164} was added to some experimental wells at a concentration of 10 ng/mL for 24 h. In some experiments, we added, 2 μM SU1498 or 2 μM Axitinib for the same time. Neuronal viability was inferred from metabolic activity determined by standard 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) reduction. For this, neurons were incubated with 0.1 mg/mL

TABLE 1 | Items evaluated in neurofunctional assessments.

Neurological assessment	Reflex	Score	Previously reported
Spontaneous activity	Exploring an open arena more than 20 s	3	Burguete et al., 2006
	Exploring between 10 and 20 s	2	
	Exploring less than 10 s	1	
	Not exploring or moving only when stimulated	0

MTT for 2 h at 37°C at the end of the analyzed period. Media was removed, and formazan precipitations were dissolved in a 4 mM HCl isopropanol solution. The absorbance of cell debris-free supernatants was read in a spectrophotometer (Beckman Coulter) with a 570 nm wavelength. Data are presented as percentage relative to the absorbance of control conditions. In some experimental conditions we corroborated neuronal viability with the life/dead fluorescence assay (Thermo Fisher Scientific) that stain live cells with calcein AM (green) and dead cells with ethidium homodimer-1 (red), following manufacturers directions.

In an independent series of experiments, neurons were subjected to the same conditions and dendritic spines were stained with the Neurite Outgrowth Staining kit (Life Technologies, Carlsbad, CA, United States) following the manufacturer directions. Briefly, neurons plated on glass coverslips were fixed with 3.7% PFA for 30 min at RT, and 1X bright orange-fluorescent dye was added to stain the outer cell membrane surfaces. After incubation with a background suppression solution, coverslips were mounted on glass slides with a permanent mounting medium with antifading agents (DAKO, Santa Clara, CA, United States). Dendritic branches were visualized using a Leica DM1000 microscope under epifluorescence illumination (568-nm excitation and 580-nm emission) with a 40X objective. A minimum of 10 neurons from 3 independent experiments was analyzed for each condition. The number of dendritic spines, defined as thin protrusions emerging from dendritic processes, extending from two to five primary dendrites/neuron was quantified for a distance of approximately 20 μm from the cell soma. Neurite lengths and spine numbers were quantified with ImageJ (NIH, United States). Spine density across all measured dendritic segments was normalized to the length of the primary dendrite.

Statistics

R- Feather Spray version 3.5.1, (R Foundation for Statistical Computing, Vienna, Austria) was used to analyze all data from *in vivo* experiments. Normal distribution in each data set was corroborated using the Shapiro–Wilk normality test. Data were tested by one-way analysis of variance (ANOVA) followed by Tukey *post hoc* test. Data were considered significant at $\alpha \leq 0.05$ level. All data are shown as mean ± 2SD. For *in vitro* experiments without normal distribution we did a Kruskal–Wallis, followed by Dunn *post hoc* test. Results are expressed as mean ± SEM.

RESULTS

VEGF Mediates Neuroprotection in the Acute Phase of Stroke

There are contradictory findings on the neuroprotective effects of VEGF in stroke. Most of the reported discrepancies can be grounded on time, dose and route of administration of exogenous VEGF in several models of stroke (Ma et al., 2012; Tovar-y-Romo et al., 2016). Because of this, we first tested the effect of administering a single bolus of 50 ng rat recombinant VEGF-A_{164} by i.c.v. injection 30 min after the beginning of reperfusion (**Figure 1**), the dose was chosen based on pilot experiments, and also on a previous study showing that this dose and method of administration is protective in other models of neurodegeneration (Tovar-y-Romo and Tapia, 2012). This protocol was carried out using a pulled glass microcapillary pipette to minimize mechanical damage in order to prevent the activation of inflammatory processes merely associated with the injection procedure. Twenty four hours after stroke, animals were evaluated in a series of neurobehavioral and motor tasks to determine the level of neurological alterations produced by the stroke (**Figure 1A**). Animals that were injected with vehicle only (DMSO + 0.1% BSA; 4 μl) showed a noticeable weakness and impaired movement of the lesioned side forelimb. These animals were unable to climb a grid and support their body weight and had a noticeable difficulty rising when placed on their sides, plus ∼60% of animals had epileptiform seizures, mostly represented by tonic-clonic convulsions, barrel rolls and running fits. Stroked rats also displayed signs of neuropathic pain when stimulated by slightly poking the affected flank. Administration of 50 ng recombinant VEGF at the beginning of reperfusion did not improve significantly the neurological deficits presented after stroke and also failed to prevent seizures.

Nonetheless, VEGF did reduce infarct volumes by about 20% in comparison to the group that received vehicle only (**Figures 1B,C**). Moreover, neuronal viability was also preserved as revealed by analyzing the somatosensory region of the parietal cortex, in which ∼50% neurons remain alive at 24 h post-stroke (**Figures 1D,E**). Therefore, with this experimental settings, we found a condition in which exogenous VEGF did produce a protective impact on brain tissue without translating into a better neurobehavioral outcome at this short time point after stroke.

VEGFR2 Activation Hinders VEGFR1-Driven Neuroprotection Elicited by Endogenous Ligand in the Acute Phase Post-stroke

It has been known for a long time that VEGF synthesis is upregulated by ischemia immediately after an experimental stroke (Hayashi et al., 1997; Plate et al., 1999; Hai et al., 2003), and this phenomenon has also been reported to occur in human patients (Issa et al., 1999). It is suspected that such VEGF increase is mechanistically involved in neuroprotection. Considering the large body of evidence that involves VEGFR2 participation in neuroprotection (Olsson et al., 2006; Tovar-y-Romo et al., 2016; Geiseler and Morland, 2018), we set out to determine whether VEGFR2 would be primordially responsible for the protection seen here. For this, we administered i.c.v. 13 nmoles of SU1498, a selective VEGFR2 inhibitor (Strawn et al., 1996), 30 min after the beginning of reperfusion and analyzed the overall effects of this procedure 24 h after stroke. Animals in this group displayed signs of neurological deficits mainly characterized by paresis of the lesioned forelimb. However, all animals in this group performed better in the neurological tests and showed significantly fewer alterations than rats that were

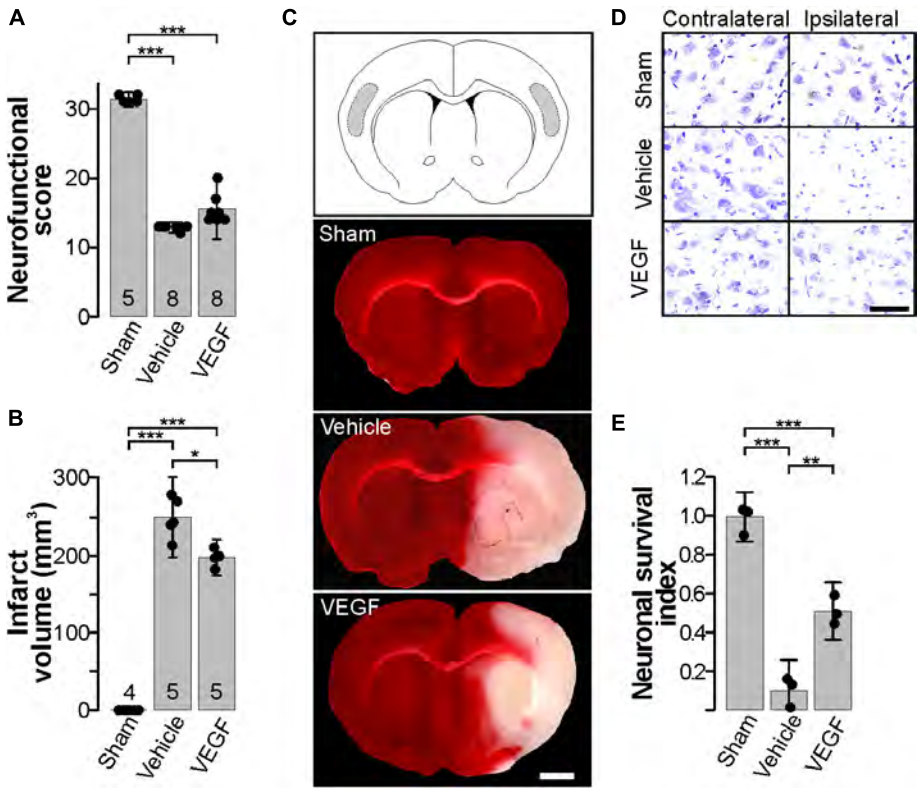

FIGURE 1 | Exogenous VEGF administration in the acute phase post-stroke is neuroprotective. **(A)** Behavioral performance of sham-operated animals and stroked rats treated with vehicle or VEGF 24 h post-stroke. Animals were assessed individually in 8 items with scoring values that added up to 32 points that corresponded to neurologically unaffected performance, see **Table 1**. **(B)** Mean infarct volume ± 2 SD of the indicated experimental groups. In **(A,B)**, the number of experiments analyzed in each group is indicated at the bottom of each column; individual data points are plotted for each group. **(C)** Representative images of thick coronal sections of brains stained with TTC from a sham-operated animal and stroked rats treated with vehicle or VEGF. The unstained (pinkish) portion of the tissue depicts the infarct. Images show brain structures at around Bregma level in the anteroposterior axis. Bar equals 2 mm. **(D)** Representative photomicrographs of Nissl-stained thin sections of the cortical areas shaded in the diagram in (top **C**). Alive neurons have a pyramidal morphology and cytosolic light violet stain, while damaged neurons appear as condensed pycnotic nuclei with enhanced concentration of the dye. Bar equals 50 μm. **(E)** Survival index represents the portion of alive neurons present at 24 h post-stroke relative to the same region in the corresponding contralateral side normalized to the number of alive neurons in sham-operated animals. $^{*}p < 0.05$, $^{**}p < 0.01$, and $^{***}p < 0.001$ in one-way ANOVA followed by Tukey *post hoc* test.

administered with vehicle alone (**Figures 2A**, **3**). Furthermore, co-administration of VEGFR2 antagonist together with a bolus of 50 ng exogenous agonist also resulted in a noticeable improvement in neurological function as compared to animals that received vehicle alone but also to the group that was administered with VEGF, which displayed better recoveries (**Figures 2A**, **3**) – thus pointing to a VEGFR2-independent effect driven by the endogenous ligand.

Given the lack of a specific pharmacological inhibitor of VEGFR1, we employed the general VEGFR inhibitor Axitinib that blocks all VEGF receptors (Inai et al., 2004). The MCAO group that received 13 nmoles of Axitinib at 30 min of the beginning of reperfusion presented exacerbated neurological symptoms described above that were followed by a lethargic state in which animals laid on their right side. As expected, infarct volumes in this group were large and comparable to the vehicle group (**Figures 1B,C**, **2B,C**). Finally, blocking all VEGFRs prevented any protection mediated by the i.c.v. administration of exogenous VEGF and animals displayed neurological impairments characteristic of large infarctions (**Figures 2A–C**). Brain damage seen in TTC stainings in this group was of proportions similar to the ones seen in the control untreated group (**Figures 2B,C**). Accordingly, neuronal death was reduced in the animals that received SU1498 alone or in combination with VEGF and was increased in animals treated with Axitinib (**Figures 2D,E**).

Correlating the neurological performance of animals 24 h after stroke to the extent of brain tissue damage allowed us to clearly segregate groups by experimental treatment and show that blocking VEGFR2 and potentiating the activation of VEGFR1 by the administration of exogenous ligand, afforded the best level of neuroprotection, closely followed by only blocking VEGFR2 (**Figure 3**). This analysis shows a strong correlation of $R^2 = 0.8747$ with a $p = 3.33 \times 10^{-16}$. The sole administration of the exogenous ligand, while still protective, does not result in a very different outcome as compared to all the non-protected experimental conditions, in which we either not treated animals or inhibited all VEGFRs (**Figure 3**).

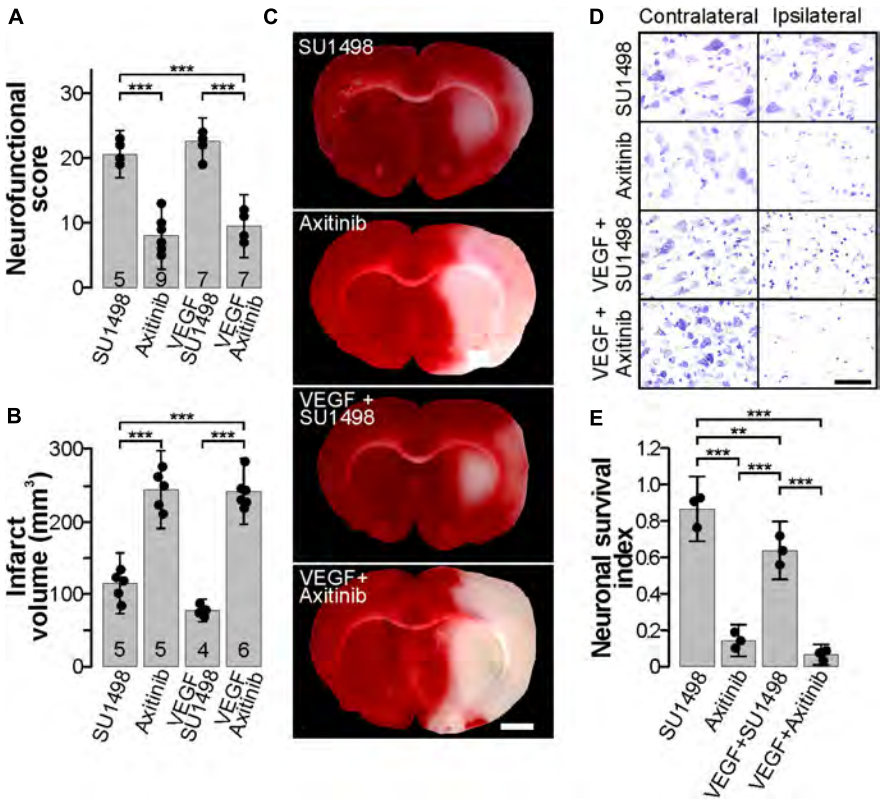

FIGURE 2 | Blocking the VEGFR2 in the acute phase post-stroke is neuroprotective. **(A)** Behavioral performance of stroked rats treated with the VEGFR2 specific inhibitor SU1498 and the pan-VEGFR inhibitor Axitinib with and without exogenous VEGF, 24 h post-stroke. **(B)** Mean infarct volume ± 2 SD of the indicated experimental groups treated with SU1498 or Axitinib alone or in combination with exogenous VEGF. In **(A,B)**, the number of experiments analyzed in each group is indicated at the bottom of each column; individual data points are plotted for each group. **(C)** Representative images of thick coronal sections of brains stained with TTC from stroked animals treated with SU1498 and Axitinib with or without exogenous VEGF. The unstained (pinkish) portion of the tissue depicts the infarct. Images show brain structures at around Bregma level in the anteroposterior axis. Bar equals 2 mm. **(D)** Representative photomicrographs of Nissl-stained thin sections of cortical areas in the somatosensory region. Alive neurons have a pyramidal morphology and cytosolic light violet stain, while damaged neurons appear as condensed pycnotic nuclei with enhanced concentration of the dye. Bar equals 50 μm. **(E)** Survival index represents the portion of live neurons present at 24 h post-stroke relative to the same region in the corresponding contralateral side normalized to the number of live neurons in sham-operated animals. $^{**}p < 0.01$ and $^{***}p < 0.001$ in one-way ANOVA followed by Tukey *post hoc* test.

VEGFR1-Mediated Neuroprotection Partially Involves M2 Polarization of Microglia With a Minimal Discernible Impact on Systemic Markers of Inflammation

VEGF drives the migration of macrophages and microglia to the damaged CNS through VEGFR1-mediated signaling (Forstreuter et al., 2002; Huang et al., 2013; Lelli et al., 2013). Therefore, we decided to study whether the neuroprotection exerted by the preferential activation of VEGFR1 would also involve the modulation of neuroinflammatory processes. We first assessed changes in inflammatory markers, both in CSF and in plasma, at 24 h post-stroke. We analyzed the content of IL-1β, IL-4, IL-6, IL-10, IL-12p70, IL-17, TNF-α, CCL11, INFγ, CX3CL1, and MIP-1α with a multiplex array for these cytokines in samples collected prior transcardial perfusion. None of the detected cytokines in CSF (IL-1β, INFγ, CXCL-3) showed a significant change compared to the values seen in the vehicle-treated group (**Figure 4A**). Likewise, for most of the peripheral markers of inflammation that produced a readable measurement in plasma, we did not find differences among experimental groups. However, we detected with this array that the inhibition of all VEGFRs with Axitinib blunted the release of peripheral markers of inflammation IL-12, TNFα, and CCL11. This blockade did not happen to the same degree when we selectively inhibited VEGFR2 (**Figure 4B**). Since under our experimental conditions we were not able to have reliable measurements of peripheral IL-1β, IL-6, and TGFβ, which have been previously identified as central players of the neuroinflammatory processes that happen after stroke, we decided to evaluate the levels of transcriptional expression of these cytokines in white blood cells collected 24 h after stroke. With RT-qPCR analyses, we determined that there are no significant changes in the level of transcription for neither of these molecules at the time point of our investigations and that VEGF or its receptors are not modifiers of these molecular responses (**Figures 4C–E**).

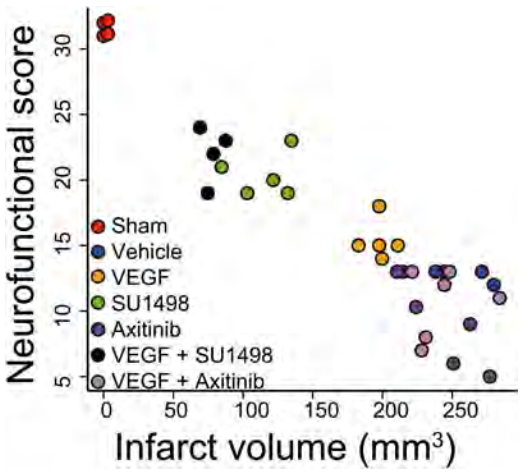

FIGURE 3 | Activation of VEGFR2 hinders VEGFR1-dependent neuroprotection afforded by the endogenous ligand. The plot shows the correlation of neurofunctional score to the infarct volume produced by MCAO in animals injected i.c.v. 30 min after the beginning of reperfusion with vehicle, or exogenous VEGF alone or in combination with VEGFR2 specific inhibitor SU1498 or VEGFR general inhibitor Axitinib. Two groups of animals that received the inhibitors individually are also presented. Each data point represents the values obtained in a single animal. Groups segregate by experimental condition and produce a strong correlation with an adjusted R^2 = 0.8747. Animals in which VEGFR2 early activation was prevented show the best levels of protection, both neurofunctional and histological, inhibiting VEGFR1 in addition to VEGFR2 blocked this effect.

Next, we looked into the polarization of microglial cells to the anti-inflammatory phenotype M2, which is known to occur in the first 24 h after stroke (Hu et al., 2012). For this, we co-stained brain sections for the microglial marker Iba-1 and the M2 marker arginase-1. Strikingly, resting state morphologically looking microglia were found to express arginase-1 in sham animals at 24 h of transiently occluding the common carotid artery (**Figure 5**). In the control MCAO group, microglia in the lesioned cortical region looked morphologically activated, mainly with shortened cellular processes and rounded somas but cells in these regions lacked the expression of arginase-1. VEGF-treated animals, however, showed activated microglia expressing the M2 polarization marker and this was also the scenario in the groups treated with the VEGFR2 inhibitor SU1498 with and without VEGF. In the case of animals injected with Axitinib, we found fewer activated microglia expressing arginase-1, suggesting that VEGFR1 blockade also reduced the polarization of microglia to the anti-inflammatory phenotype.

VEGF Acts Directly on Neurons Through the Activation of VEGFR1

In the last part of our study, we analyzed whether the effects of preferentially activating VEGFR1 and the neuroprotection seen in the *in vivo* model of ischemic stroke were derived from the direct stimulation of neuronal receptors. Using an *in vitro* model of cultured cortical neurons we first determined the expression of both, VEGFR1 and VEGFR2 in these cells. **Figure 6A** shows the expression of both TRKs at 7 DIV, specifically in neurons. Expression of both receptors is clear in neuronal somas as well as in neurites. Then, we tested whether the addition of VEGF to neuronal cultures could rescue neurons from excitotoxicity, one of the primary mechanisms underlying neuronal death after ischemia. For this, we incubated the neurons with different concentrations of the glutamatergic agonist NMDA for 24 h in the same culture media in which cells were grown for 11 days. At the lowest concentration assayed (1 μM), neuronal death is not apparent and increasing the concentration of NMDA to 10, and 100 μM gradually increased the level of neuronal death (**Figures 6B,C**). Addition of 10 ng/mL recombinant VEGF reduced in about 20% the loss of metabolic activity in the neuronal cultures, which relates to the overall health of the cells and their survivability.

Even though the lower concentrations of NMDA tested here did not produce a substantial decrease of neuronal viability, neurons exposed to these conditions developed morphological signs of structural damage, mainly characterized by dendritic spine loss. Addition of VEGF to the culture media also prevented this morphological change and preserved spine structures although it did not modify the length of primary neurites (**Figures 6D–F**). With these experiments, we showed that VEGF executes trophic effects on cortical neurons to allow them to grow healthy in culture and make them less susceptible to excitotoxic death.

Finally, in an independent set of experiments, we tested the role of VEGFR1 and VEGFR2 in driving the pro-survival effects. Strikingly, blocking VEGFR2 activation by addition of SU1498 also resulted in a significant increase in neuronal protection, which was further potentiated by the co-administration of VEGF (**Figure 6G**). By contrast, inhibiting the activation of both receptors with Axitinib prevented entirely the neuroprotection exerted by VEGF (**Figure 6G**). These results replicated well the effects that we described first with the *in vivo* model, therefore, proving that the mechanisms of protection seen partially encompassed a direct involvement of neuronal receptors.

DISCUSSION

Since VEGF is a molecule with pleiotropic actions that can execute its functions by binding a number of different receptors, the exact role of VEGF increased expression after stroke in neuroprotective mechanisms has been the core of a controversy. The prevailing idea on the dual effects exerted by VEGF states that the dominant actions of this trophic factor, whether neuroprotective or detrimental, are chiefly dictated by the timing, dosage, and route of administration in experimental models of stroke (Wittko-Schneider et al., 2013; Geiseler and Morland, 2018). Moreover, it has been amply described that excessive levels of VEGF in the early phase following stroke promote BBB alterations and a general state that favors neurodegeneration. Interestingly, delayed administration of VEGF is more likely to result in neuroprotection (Sun et al., 2003; Dzietko et al., 2013), even though, others have also reported the protective effect of an early VEGF i.c.v. administration (Kaya et al., 2005).

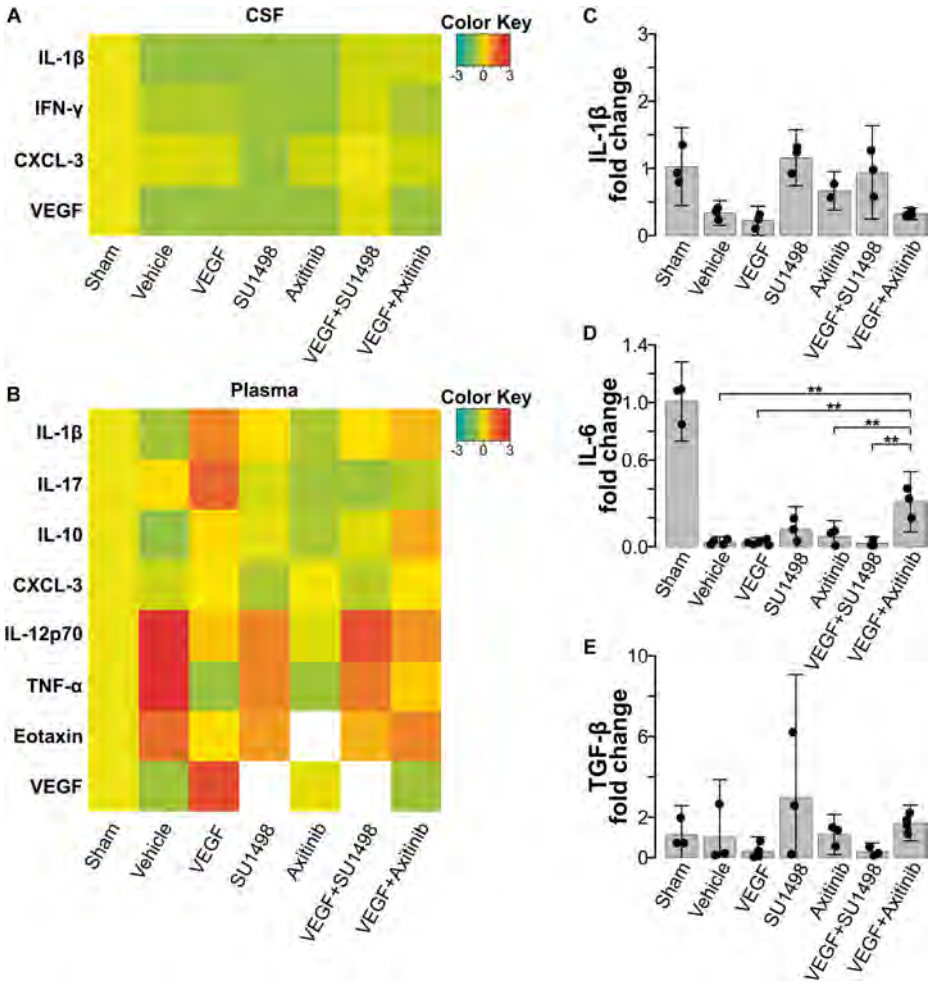

FIGURE 4 | VEGFR1-dependent neuroprotection does not reflect on changes in peripheral inflammatory markers. **(A)** Heatmap of cytokines and VEGF detected in CSF 24 h after stroke. **(B)** Heatmap of peripheral cytokines and VEGF detected in plasma 24 h after stroke. No significant differences were detected in these markers in the acute phase following stroke. White colored areas are from groups with undetectable readings. Changes in transcriptional expression of **(C)** IL-1β, **(D)** IL-6, and **(E)** TGF-β, determined by RT-qPCR relative to GAPDH in blood 24 h following stroke. No differences were found among experimental groups.

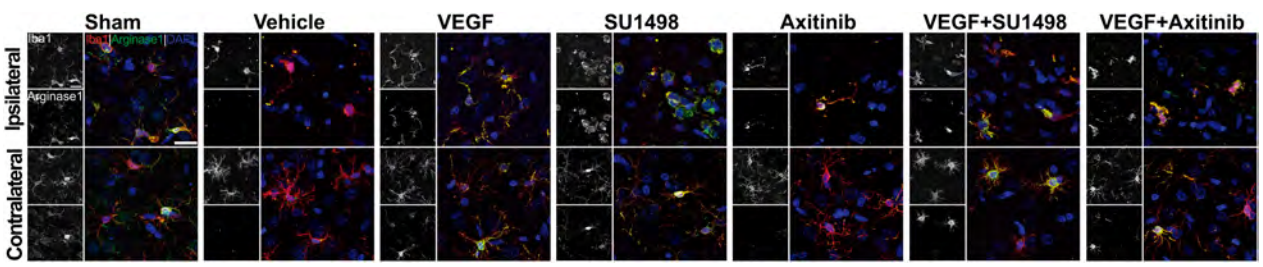

FIGURE 5 | Blockade of VEGFR1 impedes the polarization of microglia to the M2 phenotype. Representative images of brain sections co-labeled with the microglia marker Iba-1 (red) and the M2 phenotype indicator arginase-1 (green). Images were taken from the somatosensory cortex adjacent to infarct core. Ameboid-like activated morphology is present under all MCAO conditions in the ipsilateral side. M2 polarizations are evident in most of the Iba-1 positive cells in the MCAO groups treated with vehicle, VEGF, SU1498 and the combination of VEGF and SU1498. Animals injected with the pan-VEGFR blocker Axitinib do not show labeling of M2 polarization in the activated microglia on the ipsilateral side. Bar equals 20 μm.

In the brain, VEGFR1 and VEGFR2 are the most expressed receptors, with VEGFR1 showing a higher density in neurons (Yang et al., 2003; Du et al., 2010). Several reports have been published over the years indicating that VEGFR2 is the receptor predominantly responsible for neuroprotective actions, mainly by driving pro-survival signaling mediated by

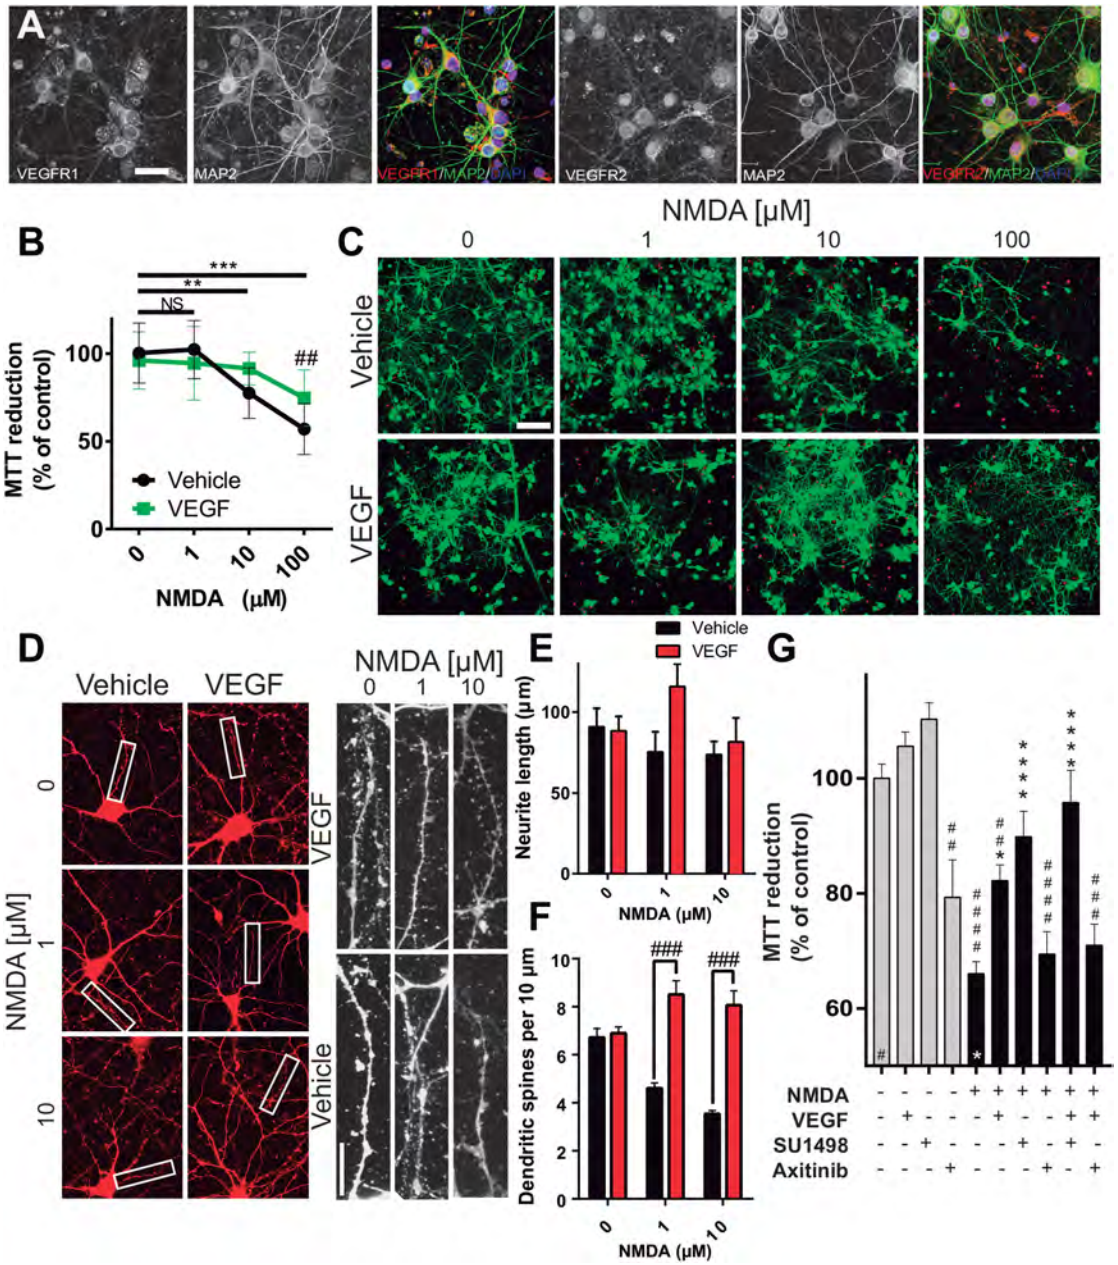

FIGURE 6 | Neuronal VEGFR1 drives neuroprotection under excitotoxic stress. **(A)** Representative photomicrographs of cultured cortical neurons labeled with the neuronal marker MAP2 (green), and VEGFR1 and VEGFR2 (red). Each column represents the mean ± SEM of the neurites of 5 neurons analyzed in three independent experiments. **(G)** Neuronal survival assessed by MTT reduction of cultures exposed to 100 μM NMDA for 24 h and 10 ng/mL VEGF alone or in combination with 2 μM SU1498 and 0.2 μM Axitinib. The graph shows the mean ± SEM of three independent experiments. $^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$, and $^{****}p < 0.0001$ compared to NMDA alone, and $^{\#\#}p < 0.01$, $^{\#\#\#}p < 0.001$, and $^{\#\#\#\#}p < 0.0001$ compared to untreated neurons in Kruskal–Wallis followed by Dunn *post hoc* test.

PI-3K/PKB and MEK/Erk pathways (Greenberg and Jin, 2013). Here, we found that the preferential activation of VEGFR1 by the endogenous ligand promotes neuronal protection and prevents the presentation of large volume infarcts; this is highly correlated with neurological performance. Of note, the concurrent activation of VEGFR2 prevents this effect, even in the

presence of excess ligand. Strikingly, such protection still happens at the cellular level, where neurons are better protected when challenged to NMDA-induced excitotoxicity by the activation of VEGFR1 if VEGFR2 is blocked.

VEGF along with its receptors 1 and 2 are transcriptionally upregulated following stroke (Hayashi et al., 1997; Issa et al., 1999; Plate et al., 1999; Marti et al., 2000; Hai et al., 2003; Stowe et al., 2007, 2008) in a long-lasting fashion (Zhang et al., 2002), through the stabilization and subsequent binding of hypoxia-inducible factor 1 (HIF-1) to the hypoxia response element sequence in their promoters (Forsythe et al., 1996). Also, it has been shown that exogenous administration of VEGF causes the upregulation of VEGFR1 and VEGFR2 (Krum et al., 2008). Cellular distribution of VEGFRs might be key in understanding the temporal regulation of vasculature adaptations in the acute phase post-stroke. In this regard, the apicobasal localization of VEGFR1 and VEGFR2 is different, where VEGFR2 is predominantly expressed in the basal side and VEGFR1 in the apical pole that produces a differential response when the ligand acts at the circulation or the parenchymal sides of endothelial cells (Hudson et al., 2014). It has also been reported that the expression of VEGFR1 is upregulated while VEGFR2 is downregulated in endothelial cells following hypoxia, which changes the VEGFR1:VEGFR2 ratio altering the ultimate responses on cell viability and recovery (Ulyatt et al., 2011). It is also important to point out that the affinity of VEGFR1 for VEGF is about 1 order of magnitude higher than the one for VEGFR2 (K_d 2–10 pM for VEGFR1 and 75–250 pM for VGFR2) (de Vries et al., 1992; Ferrara, 2004; Shibuya, 2006). Although VEGFR3 is expressed in the adult rat brain (Hou et al., 2011), we ruled out the participation of this receptor in the neuroprotection seen here, even when it can also be inhibited by Axitinib, because it does not get activated by VEGF-A (Olsson et al., 2006; Leppänen et al., 2013) and its expression is primarily restricted to lymphatic endothelial cells (Iljin et al., 2001), which have a very low relative abundance in the brain (Louveau et al., 2015).

Our observations lead to reaffirm the critical role of VEGFR1 in the endogenous neuroprotective mechanisms elicited after ischemic insults to the brain. In this regard, it is known that the deletion of VEGF-B, a specific ligand for VEGFR1, produces 50% larger infarcts in mice when subjected to the permanent occlusion of the MCA in comparison to WT animals, by inhibition of apoptotic executioner molecules (Li et al., 2008). Protein analysis identified a significant increase of VEGF-B in CSF and the ischemic hemispheres, with increased VEGFR1 activation that also correlated with an increase in Akt phosphorylation, whereas an increase in VEGF in the contralateral hemisphere correlates with a significant increase in vascular density 7 days post-stroke (Guan et al., 2011). VEGFR1 activation in pericytes promotes the formation of stable new vessels in a mechanistic way independent of endothelial cells, and also slightly attenuated inflammation when administered in the sub-acute phase post-stroke (Jean LeBlanc et al., 2018). In this sense, it has also been shown that PlGF, a specific ligand for VEGFR1, is the most efficient promoter of angiogenesis, which produces mature non-leaky new vessels (Luttun et al., 2002; Gaál et al., 2013).

The direct VEGFR1 activation in neurons might be a mechanism more relevant than promoting healthy angiogenesis (Poesen et al., 2008; Dhondt et al., 2011; Ishrat et al., 2018). In this regard, it is noteworthy that VEGF associates to neurons in infarct and peri-infarct brain regions in a non-human primate model of stroke (Stowe et al., 2007), and interestingly, such association can even be more relevant than the interaction of this growth factor with astrocytes (Shen et al., 2018). Our results, however, indicate that all these neuroprotective mechanisms driven by VEGFR1 are suppressed in the first hours following stroke by the activation of VEGFR2. The exact mechanisms underlying this phenomenon are not fully elucidated, but they might involve the suppression of endoplasmic reticulum stress and apoptosis (Feng et al., 2019).

VEGF has some interesting roles in regulating neuroinflammation. It has been shown that macrophages express more VEGF in response to disturbances in brain metabolic homeostasis, especially responding to decreased glucose incorporation (Jais et al., 2016), and microglia in chronically affected regions of CNS upregulate their expression of VEGF (Nikodemova et al., 2014). However, not much is known about the involvement of VEGF, or its receptors, in the polarization of macrophages/microglia under inflammation. Interestingly, very recent evidence indicates that the antiangiogenic VEGF isoform $VEGF_{164}b$ is capable of blocking VEGFR1 prompting the M1 polarization of peripheral macrophages (Ganta et al., 2019), although it is known that this form of VEGF has neuroprotective effects in the CNS (Beazley-Long et al., 2013). Also, M2-polarized peripheral macrophages in culture are known to upregulate their VEGFR1 mRNA expression (Melton et al., 2015), which in microglial cells could lead to the inhibition of the expression of the scavenger receptor A following stroke (Xu et al., 2017). With the determinations carried out in the present study, we were unable to obtain reliable readings of the levels of soluble mediators of inflammation poured on CSF and plasma, however, many of these markers, like IL-6, have been disregarded as important predictors of the outcome (Clark Wayne et al., 2000; Worthmann et al., 2010). Nonetheless, we could characterize the overall response of microglia polarizing to the anti-inflammatory phenotype under the experimental conditions that allow the activation of VEGFR1. More detailed analyses are required to characterize these responses at the molecular and cellular levels.

CONCLUSION

We found that the activation of VEGFR2 in the first hours post-stroke obstructs endogenously-coded mechanisms of adaptation to injury in the brain. We propose here the existence of a VEGFR2-mediated antagonism of VEGFR1, which has not been reported previously. This process would constitute a fundamental mechanism of endogenous operations that drive adaptive responses in the brain after stroke that is worthy of further exploration. Our results also strengthen the notion that VEGFR1 has a critical role in neuroprotection, and that targeting this receptor would be useful at developing restorative therapies for stroke.

DATA AVAILABILITY

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

ETHICS STATEMENT

This study was carried out in accordance with the Mexican law for the use and care of laboratory animals (NOM-062-ZOO-1999) with the approval of the Institutional Animal Care and Use Committee (CICUAL-IFC-LTR93-16).

AUTHOR CONTRIBUTIONS

AC-R and LT-y-R conceived the project and designed the experiments. AC-R conducted the *in vivo* experiments, wrote the R-based scripts to process data, and carried out statistical analyses. YH-R cross-validated the neurological assessments. ANC-R and AP-P conducted the *in vitro* experiments. RR-H was responsible for confocal microscopy acquisition and analyses. AC-R, ANC-R, YH-R, and LT-y-R analyzed the data. LT-y-R wrote the manuscript. All authors read and approved the final version of the manuscript.

FUNDING

This work was supported by the Programa de Apoyo a Proyectos de Investigación e Innovación Tecnológica, Dirección General de Asuntos del Personal Académico (IN226617), Consejo Nacional de Ciencia y Tecnología (CONACYT; CB219542/13219), and the Committee for Aid and Education in Neurochemistry of the International Society for Neurochemistry and the International Brain Research Organization Return Home Program (2014) grants to LT-y-R. AC-R, ANC-R, and YH-R are recipients of doctoral scholarships from the CONACYT (280986/277660/428473).

ACKNOWLEDGMENTS

We thank Jaime Rogerio Ríos for his contribution with microglia immunofluorescence stainings, Cristina Aranda Fraustro for administrative assistance, Dr. Laura Ongay-Larios for her expert aid with RT-qPCR, and Gabriela Meneses and Dr. Edda Sciutto for their helpful assistance with the MAGPIX system. AC-R conducted this study in partial fulfillment of the requirements of the Programa de Doctorado en Ciencias Biomédicas of Universidad Nacional Autónoma de México.

Abstract

G protein-coupled receptors (GPCRs) are transmembrane proteins that have an important impact in a myriad of cellular functions. Posttranslational modifications on GPCRs are a key processes that allow these proteins to recruit other intracellular molecules. Among these modifications, phosphorylation is the most important way of desensitization of these receptors. Several research groups have described two different desensitization mechanisms: heterologous and homologous desensitization. The first one involves the phosphorylation of the receptors by protein kinases, such as PKC, following the desensitization and internalization of the receptor, while the second one involves the phosphorylation of the receptors by GRKs, allowing for the receptor to recruit β-arrestins to be desensitized and internalized.

Methods in Cell Biology, Volume 149, ISSN 0091-679X, https://doi.org/10.1016/bs.mcb.2018.08.004

Interestingly, a few number of studies have described the participation of β-arrestins during the heterologous desensitization process. Hence, the aim of this review is to briefly explore the role that β-arrestins play during the heterologous desensitization of several GPCRs.

1 INTRODUCTION

G protein-coupled receptors (GPCRs) have an important impact in a great variety of cellular processes (Bockaert & Pin, 1999; Kumari, Gosh, & Shukla, 2015; Miao & McCammon, 2016). The superfamily of GPCRs involves almost 1000 members that are encoded by the genome (Ikeda, Sugihara, & Suwa, 2018; Santos et al., 2017), and they are well known to be the target of almost 20–40% of the current therapeutic drugs in the market (Celebiro & Godbole, 2018; Insel et al., 2018; Smith, Lefkowitz, & Rajagopal, 2018). Currently, almost 30 GPCRs have been crystalized, allowing not only for a high resolution view of the receptor in order to design more specific drugs with less side effects (Grisshammer, 2017; Kruse, Manglik, Kobilka, & Weis, 2013; Stauch & Cherezov, 2018) but also to elucidate the residues and the intracellular domains that are responsible for the binding to other intracellular proteins (Deupi, 2014; Kang et al., 2015; Lu & Wu, 2016). One of the molecules that are known to bind GPCRs after being phosphorylated, is β-arrestins. These proteins were originally discovered due to their ability to desensitize and internalize several activated GPCRs during homologous desensitization (Carmona-Rosas, Alcantara-Hernandez, & Hernandez-Espinoza, 2018), however, recent studies have demonstrated that β-arrestins are also able to desensitize and internalize receptors during heterologous desensitization (Shi et al., 2017; Zhang & Kim, 2017). This means that the recruitment of β-arrestins to a GPCR may occur when the receptor is phosphorylated both in ligand-dependent and -independent fashions (Bohn, Lefkowitz, & Caron, 2002; Chaturvedi et al., 2018; Ranjan, Dwivedi, Baidya, Kumar, & Shukla, 2017). In addition to this, we recently described that β-arrestins are important scaffold proteins that need to be recruited to a receptor in order to form the multi-protein complex GPCR/β-arrestin/ERK1/2, which is able to activate different downstream signaling pathways (Carmona-Rosas et al., 2018). We do not pretend to present a vast analysis of the few studies that reported the recruitment of β-arrestins to the receptor during the heterologous desensitization process, but rather, describing the key elements of such interaction and the subsequent signaling pathways that are activated.

2 THE FORMATION OF GPCR/β-ARRESTIN COMPLEXES DURING THE HOMOLOGOUS AND HETEROLOGOUS DESENSITIZATION PROCESSES

GPCR desensitization is understood as a decrease in the coupling between the phosphorylated receptor and the G proteins. This process allows for the receptor to be internalized through the endocytic machinery, resulting in an important decline of

the receptor response (Magalhaes, Dunn, & Ferguson, 2012). Currently, there are two main types of desensitization: (1) homologous desensitization, which is the result of the activation of the receptor by a ligand and the phosphorylation of the receptor intracellular domains, by G protein-coupled receptor kinases (GRKs), hence, resulting in the internalization of the receptor by their coupling to β-arrestin proteins (Shenoy & Lefkowitz, 2011). The latter proteins were described as scaffold elements that the GPCRs employ to amplify their signaling pathways and to be internalized into clathrin-coated pits (Delom & Fessart, 2011; Irannejad et al., 2013; Puthenveddu & Von Zastrow, 2006) and (2) heterologous desensitization, which is a ligand-independent process where the receptor is phosphorylated in its intracellular domains by second messenger-dependent protein kinases, such as protein kinase A (PKA) or protein kinase C (PKC) (Benovic et al., 1985).

Understanding the interaction between the homologous and heterologous desensitization of GPCRs is currently an important field of study. Several reports have related GRK2 and β-arrestins with the PKA/PKC-mediated regulatory pathway. For example, the activated GRK2 is able to bind PKCβ through its pleckstrin homology domain, resulting in the inhibition of PKC. In addition, β-arrestins are able to inhibit the PKC-mediated regulatory pathways through the recruitment and activation of the diacylglycerol (DAG) kinase, which subsequently regulates the conversion of DAG into phosphatidic acid (PA). Besides, it has been reported that β-arrestins can recruit cAMP phosphodiesterases to ligand-activated receptors, promoting the degradation of cAMP, and inhibiting the activation of PKC (Fig. 1A) (Zhang & Kim, 2017).

2.1 THE ROLE OF β-ARRESTINS IN GPCR REGULATION

Even though β-arrestins are known to hinder the binding of the receptor with the G protein, different studies have reported that the conformation of the supercomplex GPCR-β-arrestin–G protein exists, which allows the receptor to keep signaling in a β-arrestin- and G protein-dependent fashion while internalized. It is important to mention that the formation of this multi-protein complex is particular of class B receptors, which have a great number of serine and threonine residues in the C-terminal tail, enabling the recruitment of β-arrestins (Thomsen et al., 2016). On the other hand, class A receptors are known to have less phosphorylated residues in the C-terminal tail, which impairs the binding of β-arrestins to the receptors. In addition, class B receptors may undergo homologous and heterologous desensitization, being the phosphorylation of the receptor the main signal that allows the binding of β-arrestins and the subsequent internalization and trafficking of the receptors (Oakley, Laporte, Holt, Caron, & Barak, 2000). This process has been demonstrated with several GPCRs, in particular with the β2-adrenergic receptor, (β2-AR), a class A receptor, where the addition of phosphoacceptor residues in the C-terminal tail, improves the binding of β-arrestin 2 to the receptor (Zindel et al., 2015). The participation of β-arrestins in the regulation of GPCRs is a key process that allows for the regulation of these receptors and the activation of different signaling

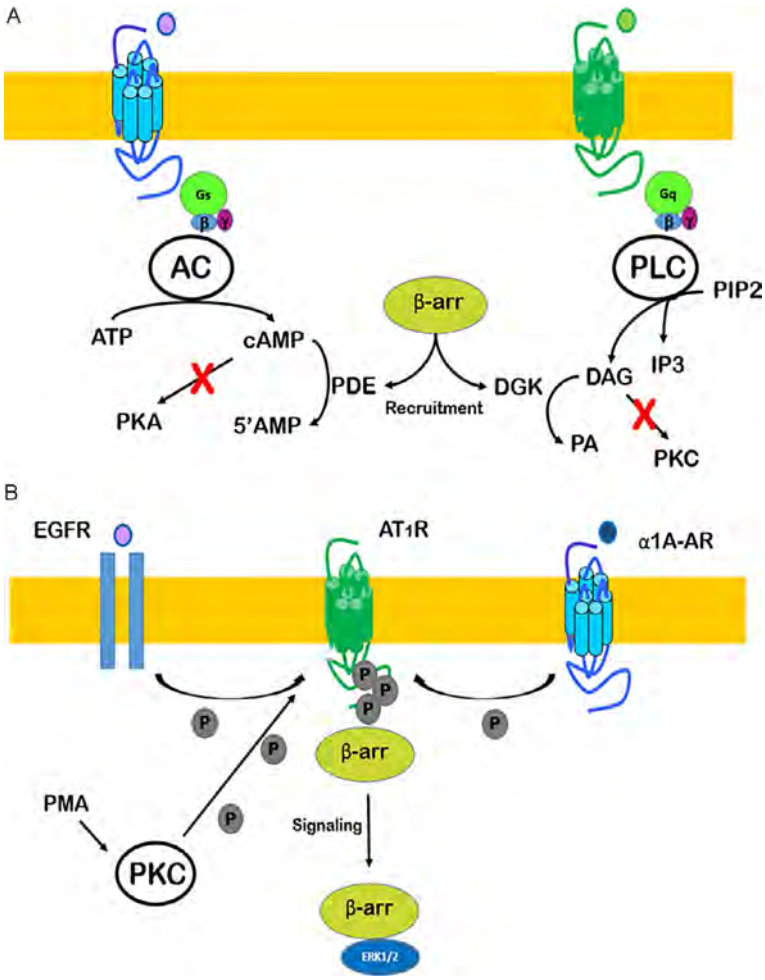

FIG. 1

Schematic representations of the putative roles of β-arrestins during GPCR heterologous desensitization. (A) β-Arrestins are able to inhibit the PKC-mediated signaling pathways through the activation of the diacylglycerol (DAG) kinase, which is responsible for the conversion of DAG into phosphatidic acid (PA), hence, decreasing the activity of PKC. In addition, β-arrestins are able to activate and recruit cAMP phosphodiesterases to ligand-activated receptors, fostering the degradation of cAMP, and inhibiting the activity of PKC. (B) The recruitment of β-arrestin 2 to the unstimulated angiotensin 1 receptor (AT1) is regulated by the activation of PKC, the α1A-adrenergic receptor (α1A-AR), and the epidermal growth factor receptor (EGFR), which in turn, promotes the phosphorylation of the AT1 receptor and the recruitment of β-arrestin 2.

pathways, such as the MAPK cascade (Carmona-Rosas et al., 2018). Interestingly, a few number of studies have reported the participation of these scaffold proteins during the heterologous desensitization of several GPCRs, opening a new way of studying the regulation of these transmembrane proteins.

3 THE ROLE OF β-ARRESTINS IN HETEROLOGOUS DESENSITIZATION: DESCRIBING A FEW NUMBER OF STUDIES

During the last years, several studies have reported the participation of β-arrestins during the homologous desensitization. However, little is known about the role that these proteins play during the heterologous desensitization process. Our research group recently reported that the activation of the sphingosine-1-phosphate receptor (S1P) allows for the binding of β-arrestin 2 to the α1B-adrenergic receptor (α1B-AR) (Castillo-Badillo et al., 2015). In addition, we also reported that the phosphorylation of the α1A-adrenergic receptor (α1A-AR) by PKC induces the binding of endogenous β-arrestin 1/2 to the receptor. These results were further confirmed by coimmunoprecipitation assays of the α1A-AR and the endogenous β-arrestins 1/2 (Alcántara-Hernández et al., 2017). Along the same lines, it has been reported that the activation of some GPCRs coupled to the G_s and G_q proteins promotes the phosphorylation of cardiac β2-AR by PKA and PKC. This process allows for the binding of the phosphodiesterase 4D (PDE4D) to the phosphorylated receptor in a β-arrestin-dependent manner. Subsequently, the PDE4D will have the role of hydrolyzing the cAMP generated by the activation of the β2-AR.

Another study reported that in neurons from the locus curelous, the brief stimulation of the μ-opioid receptor with Met^5-enkephalin, causes its homologous desensitization, however, longer times of stimulation produces the heterologous desensitization of the α2-adrenergic receptors (α2-ARs). Such heterologous process is regulated by β-arrestin 2 and the activation of ERK1/2. Interestingly, the inhibition in the expression of β-arrestin 2 does not have an effect in the internalization of the μ-opioid receptor, but does have an impact in the heterologous desensitization of the α2-ARs (Dang, Chieng, & Christie, 2012). This interesting study suggests that the recruitment of β-arrestin to the α2-ARs by heterologous desensitization, enables the formation of a multi-protein complex that involves the α2-ARs, β-arrestin 2, and ERK1/2. Disruption at any protein level inhibits the assemble of such complex. In addition, the activation of the neuropeptide FF2 receptor was sufficient to recruit β-arrestin 2 to the μ-opioid receptor, but not to induce its internalization. Besides, this recruitment of β-arrestin is the result of the phosphorylation of the receptor at serine 377 by GRK2, but not by PKA or PKC as would be expected in a heterologous desensitization model (Mouledous et al., 2012). Along the same lines, the phosphorylation of the δ-opioid receptor at serine 344 by PKC leads to the heterologous desensitization of this receptor, which is also regulated by the recruitment of β-arrestins and the internalization of the receptor into clathrin-coated vesicles (Xiang et al., 2001).

Interestingly, another study reported the participation of PKC in the phosphorylation and internalization of the dopamine 2 receptor (D2). In such study, it was described that the pharmacological activation of PKC induces the phosphorylation of multiple sites within two main domains in the C-terminal tail of the D2 receptor, resulting in the recruitment of β-arrestins and the desensitization and internalization of the receptor (Namkung & Sibley, 2004). Similarly, this was not the only study that related the activation of PKC with the phosphorylation and subsequent internalization of the D2 receptor. The activation of the neurotensin receptor 1 (NT1R) leads to the PKC-mediated phosphorylation of the D2 receptor, triggering the recruitment of β-arrestin 1, and the uncoupling of the receptor with the G protein (Thibault, Albert, Pineyro, & Trudeau, 2011).

Recently, it was also described that the activation of PKC, $G_{q/11}$ GPCRs, and epidermal growth factor receptor (EGFR), promotes the recruitment of β-arrestin 2 to the unstimulated angiotensin 1 receptor AT1 (Fig. 1B). This process enables for the formation of a stability lock, which depends on the phosphorylated residues located in the C-terminal tail of the receptor and two conserved phospho-binding lysines in the β-arrestin 2 N-terminal domain. This process also promotes the activation of the MAPK pathway, which depends on the internalization of the receptor by β-arrestin 2. This study suggests that the solely phosphorylation of the receptor is sufficient to recruit and activate β-arrestins, which may serve as a novel mechanism of β-arrestin activation (Toth et al., 2018).

Finally, it has been described that chronic insulin treatment of Rat1 fibroblast leads to the downregulation of β-arrestin 1 through ubiquitination and proteosomal degradation, which is associated with a decrease in insulin growth factor receptor I (IGF-I), lysophosphatidic acid (LPA), and β2-AR stimulation of the MAP kinase pathway. This deficit in the activation of such kinases was restored by the expression of exogenous wild-type β-arrestin 1 in insulin-treated cells. This suggests that the insulin-induced decrease in β-arrestin 1 plays a role in the activation of the MAP kinase signaling pathway triggered by some GPCRs (Dalle et al., 2002).

4 CODA/FUTURE DIRECTIONS

The regulation of GPCRs by β-arrestins is a process that has been extensively described for many research groups. It has been proposed that several receptors have a particular phosphorylation bar code, which allows the receptors to bind β-arrestins and use this interaction to activate other signaling pathways (Zhou et al., 2017). Even though this interaction has been characterized in homologous desensitization models, little is known about such interaction during the heterologous desensitization process. Efforts have to be done in order to further understand this cellular process. Additionally, it would be of great interest to explore the heterologous desensitization of other RTKs and their binding to β-arrestin 1/2, which could open the possibility to design new drugs with less side effects.

ABSTRACT

The human α_{1D}-adrenergic receptor is a seven transmembrane-domain protein that mediates many of the physiological actions of adrenaline and noradrenaline and participates in the development of hypertension and benign prostatic hyperplasia. We recently reported that different phosphorylation patterns control α_{1D}-adrenergic receptor desensitization. However, to our knowledge, there is no data regarding the role(s) of this receptor's specific phosphorylation residues in its subcellular localization and signaling. In order to address this issue, we mutated the identified phosphorylated residues located on the third intracellular loop and carboxyl tail. In this way, we experimentally confirmed α_{1D}-AR phosphorylation sites and identified, in the carboxyl tail, two groups of residues in close proximity to each other, as well as two individual residues in the proximal (T442) and distal (S543) regions. Our results indicate that phosphorylation of the distal cluster (T507, S515, S516 and S518) favors α_{1D}-AR localization at the plasma membrane, i. e., substitution of these residues for non-phosphorylatable amino acids results in the intracellular localization of the receptors, whereas phospho-mimetic substitution allows plasma membrane localization. Moreover, we found that T442 phosphorylation is necessary for agonist- and phorbol ester-induced receptor colocalization with β-arrestins. Additionally, we observed that substitution of intracellular loop 3 phosphorylation sites for non-phosphorylatable amino acids resulted in sustained ERK1/2 activation; additional mutations in the phosphorylated residues in the carboxyl tail did not alter this pattern. In contrast, mobilization of intracellular calcium and receptor internalization appear to be controlled by the phosphorylation of both third-intracellular-loop and carboxyl terminus-domain residues. In summary, our data indicate that a) both the phosphorylation sites present in the third intracellular loop and in the carboxyl terminus participate in triggering calcium signaling and in turning-off α_{1D}-AR-induced ERK activation; b) phosphorylation of the distal cluster appears to play a role in receptor's plasma membrane localization; and c) T442 appears to play a critical role in receptor phosphorylation and receptor-β-arrestin colocalization.

1. Introduction

G protein-coupled receptors (GPCRs) are the most abundant class of sensors of the external (light, odors, tastants) and the internal (hormone, neurotransmitters, autacoids) mileaux [1]. These receptors participate in essentially all key physiological processes and are involved in the development of many diseases, making them the target of 20–40% of current therapeutic drugs on the market [2,3]. Among the GPCR family are the adrenergic receptors. These receptors have been classified into α_1-, α_2-, and β-adrenergic subfamilies on the basis of their structure and signaling; each subfamily is formed by three members [4]. In turn, the α_1-adrenergic receptors (α_1-ARs) are composed of the α_{1A}-, α_{1B}- and α_{1D}- subtypes; the latter receptor was the subject of the present work.

As are all the members of the GPCR family, α_{1D}-ARs are constituted of seven membrane-spanning domains connected by three extracellular and three intracellular loops, an extracellular amino terminus, and an intracellular carboxyl tail (CTail) [4]. α_{1D}-ARs have some unique features that have made their study very challenging. For example, α_{1D}-ARs have been difficult to detect in many tissues [5] and, when overexpressed, they have a low level of expression at the plasma membrane, being mainly localized in intracellular vesicles [6–9]. Additionally, α_{1D}-

INFORME DE LABORES 2019

ARs have constitutive activity with physiological and pathophysiological relevance; in particular this receptor subtype appears to be involved in the regulation of tissue perfusion and the control of blood pressure, and in the pathogenesis of hypertension [10–20]. Deletion of the first α_{1D}-AR 79 amino acids increases its localization at the plasma membrane [7,8,21–24]. Interestingly, cleavage in the amino terminus occurs endogenously in human cell lines, which suggests that this could be a physiological mechanism employed by cells to generate functional α_{1D}-ARs localized at the plasma membrane [25]. Once at the plasma membrane, α_{1D}-ARs appear to have a conserved mechanism of action: agonist binding to the receptor's extracellular region induces transmembrane conformational changes, which trigger intracellular $G_{q/11}$ -receptor interactions. This activates phosphatidylinositol 4, 5 bisphosphate hydrolysis by PLC-β, generating inositol 1, 4, 5-trisphosphate and diacylglycerol. Inositol trisphosphate causes the release of calcium from intracellular stores, while diacylglycerol is able to activate protein kinase C (PKC) and together these mediators intracellularly propagate the signal. Sustained α_{1D}-AR stimulation triggers the binding of G protein-coupled receptor kinases (GRKs) and the phosphorylation of α_{1D}-ARs third intracellular loops and carboxyl tails, which reduces responsiveness through a mechanism known as homologous desensitization [22–24,26,27]. Additionally, PKC activation induces α_{1D}-AR phosphorylation and reduces responsiveness, a process known as heterologous desensitization [22–24,26,27]. During the former processes, the scaffold protein, β-arrestin, seems to associate with the receptor-signaling complex, favoring the action of the endocytic machinery, receptor internalization, and putatively switching from G protein-mediated to β-arrestin-mediated signaling [28–33].

As compared to other members of the α_1- subfamily, α_{1D}-AR regulatory mechanisms remain poorly characterized. It is known that agonists, such as noradrenaline (NA), and pharmacological activation of PKC by phorbol 12-myristate 13-acetate (PMA) induce phosphorylation and desensitization of α_{1D}-ARs [10,22,26,27]. Using mass spectrometry analysis, our group recently reported distinct α_{1D}-AR phosphorylation patterns in response to NA or PMA [22]; the data suggested possible roles of GRK2 and conventional PKC isoforms α and β in phosphorylations associated with α_{1D}-AR homologous and heterologous desensitization. Six phosphorylated residues in the α_{1D}-AR third intracellular loop (IL3) and nine in the CTail were detected consistently and with high probability [22]. This large number of phosphorylation sites and their location in different receptor domains complicate the experimental analysis of their functional relevance. Hence, the aim of the present work was to further explore the role of some of these residues in α_{1D}-AR function. In order to tackle this issue, we generated several receptor mutants and assessed their phosphorylation state, internalization, and β-arrestin binding, as well as activation of ERK 1/2 and calcium signaling. Here we show that residues located in the carboxyl tail play roles in the signaling and subcellular location of this adrenergic receptor. Our data indicate that there are different points of regulation controlled by phosphorylated residues in close proximity in the α_{1D}-AR CTail.

2. Materials and methods

2.1. Reagents

(−)-Noradrenaline (NA), propranolol, BMY 7378, phorbol myristate acetate (PMA), and lysophosphatidic acid (LPA) were obtained from Sigma-Aldrich Chemical. AG1478 was obtained from Calbiochem and EGF was obtained from Preprotech. [^{32}P]Pi (8500–9120 Ci/mmol) was obtained from Perkin-Elmer Life Sciences. Dulbecco's modified Eagle's medium, fetal bovine serum, trypsin, Lipofectamine 2000, amphotericin B, streptomycin, penicillin, doxycycline hyclate, hygromycin B, blasticidin, and Fura-2 AM were purchased from Invitrogen-Life Technologies. Wheat germ agglutinin Alexa Fluor-350 conjugate (catalog number W11263), Super Signal West Pico chemiluminescence kits, small interfering RNA (siRNA) for β-arrestin 1 (catalog number AM16708, lot AS027ZUU), β-arrestin 2 (catalog number AM16708, lot AS027ZUT), and scrambled siRNA (catalog number AM4611, lot AS026WKE) were obtained from Thermo Fisher. Polyvinylidene difluoride and nitrocellulose membranes were obtained from BioRad. Polyethyleneimine was obtained from Polyscience. Agarose-coupled protein A was obtained from Merck-Millipore. Monoclonal anti-GFP was from Clontech (catalog number 632381, lot A5033481) and polyclonal anti-GFP was generated in our laboratory [22,23,34]. Anti-phospho-ERK 1/2 (Thre202/Tyr204) (catalog number 9101S, lot: 30) and anti-total ERK (p42/44) (catalog number 4695S, lot: 21) antibodies were obtained from Cell Signaling Technology; β-Arrestin-1/2 (catalog number sc-7491, lot D1615) monoclonal antibody was obtained from Santa Cruz Biotechnology (Sc-74,591). Tetramethyl-rhodamine-conjugated AffiniPure anti-donkey mouse IgG (code 715-025-150) was from Jackson Immunology. were purchased from Thermo Fisher Scientific. Secondary antibodies were obtained from Jackson ImmunoResearch and Zymed (Thermo Fisher Scientific). Antibody dilutions were 1:1000 for primary antibodies and 1:10,000 for secondary antibodies.

2.2. Plasmids

cDNA coding for either amino terminus-truncated or amino- and carboxyl termini-truncated-α_{1D}-AR-EGFP (Enhanced Green Fluorescent Protein) constructs (Δ1–79 and Δ1–79 and Δ440–572, respectively [24]) were subcloned into pEGFP-N1 (Clontech). These constructs were further subcloned into pCDNA5/FRT/TO to generate pΔN-α_{1D}-AR-EGFP and pΔNΔC-α_{1D}-AR-EGFP (Flp-ln T-Rex expression system, Invitrogen), as previously described [22]. The latter constructs were mutagenized to change the detected phosphorylated serines and threonine 328 in IL3 [22] into alanines or valine, respectively (S300/323/331/332/334A,T328 V) i. e., plasmids: pΔN-α_{1D}-AR-MutIL3-EGFP and pΔNΔC-α_{1D}-AR-MutIL3-α_{1D}-AR-EGFP. The pΔN-MutIL3-α_{1D}-AR-EGFP construct was then used as a template to mutagenize and generate the following mutants: 1) T442V, 2) S543A, 3) T477V,S486/492A, 4) T507V,S515/516/518A, 5) T477V, S486/492A,T507V,S515/516/518A, 6) T442/477V,S486/492A,T507V, S515/516/518/543A, 7) T477D,S486/492D, 8) T507D,S515/516/518D and 9) T442/477D,S486/492D,T507D,S515/516/518/543D. All these constructs were performed by Mutagenex, Inc. and proper modification was confirmed through sequencing by the same company.

2.3. Cells and transfection

HEK293 cells do not seem to express α_1-ARs as evidenced by the absence of calcium response to NA (in the presence of propranolol) [35] and specific radioligand binding (unpublished). Parental Flp-In T-Rex HEK293 cells (Invitrogen) were grown in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum, 100 μg/ml streptomycin, 100 U/ml penicillin, and 0.25 μg/ml amphotericin B. To generate inducible receptor-expressing cells, parental Flp-In T-Rex HEK293 cells were transfected with pCDNA5/FRT/TO, containing the cDNA coding for the previously described α_{1D}-AR mutants, and pOG44 using Lipofectamine 2000 following the manufacturer's instructions. Transfected cells were selected with 100 μg/ml hygromycin B and 5 μg/ml blasticidin, as previously described [22,36]. Receptor expression was induced with 1 μg/ml doxycycline hyclate 14–24 h before performing experiments. In all experiments using NA, 1 μM propranolol was also present, to avoid any β-adrenergic action; the addition of propranolol by itself had no impact on any of the parameters studied. In experiments in which the expression of β-arrestin 1/2 was knocked down, both the β-arrestin 1 and 2 siRNA (50 nmol final of each plasmid for each 3 cm-diameter dishes) were combined and transfected using Lipofectamine 2000, following the manufacturer's instructions, and cells were cultured for 48 h prior to being used.

INFORME DE LABORES 2019

2.4. Receptor phosphorylation

Receptor phosphorylation was performed as previously described [22,24]. In brief, cells, cultured in six well plates, were incubated for 3 h in phosphate-free Dulbecco's Modified Eagle's media supplemented with 50 μCi/ml [^{32}P]Pi. Labeled cells were stimulated with the indicated compounds, washed with ice-cold phosphate-buffered saline (PBS) solution and solubilized for 1 h in the lysis buffer [22,24]. The extracts were centrifuged and supernatants were incubated overnight with protein A-agarose and anti-EGFP antiserum. Samples were subjected to SDS-PAGE, transferred onto nitrocellulose membranes and exposed for 24 h. The amount of phosphorylated receptor was assessed by PhosphorImager analysis. Western blotting for loading controls was performed using monoclonal anti-EGFP antibodies.

2.5. Intracellular calcium determinations

Intracellular calcium concentrations were determined as previously described [22,24]. In brief, cells were serum-starved for 2 h, then loaded with 2.5 μM Fura-2/AM for 1 h at 37 °C. Labeled cells were washed three times to eliminate unincorporated dye. Fluorescence measurements were assessed at 340- and 380-nm excitation wavelengths and at a 510-nm emission wavelength, with a chopper interval set at 0.5 s, using an Aminco-Bowman Series 2 Luminescence Spectrometer. Intracellular calcium levels were calculated as described by Grynkiewicz et al. [37].

2.6. ERK 1/2 phosphorylation

Cells were serum-starved for 2 h before experiments. After stimulation with the indicated compounds, cells were washed with ice-cold PBS and lysed with Laemmli sample buffer [38]. Lysates were centrifuged at 12,000 × *g* for 5 min, and proteins in supernatants were separated by SDS-PAGE. Proteins were electrotransferred onto polyvinylidene difluoride membranes and immunoblotting was performed. Duplicate samples were run in parallel to determine total-ERK and phospho-ERK 1/2. For data normalization, the maximal response was considered as 100%.

2.7. Intracellular fluorescence, receptor internalization and colocalization with endogenous β-arrestin 1/2

Receptor internalization and colocalization assays with endogenous β-arrestin 1/2 were performed as described [22,39]. In brief, cells were seeded to reach 50% confluence into glass-bottomed Petri dishes and were cultured for 24 h at 37 °C in media containing 1% serum and stimulated with NA or PMA. After stimulation, the cells were washed with PBS, fixed with 4% paraformaldehyde in 0.1 M phosphate buffer for 30 min at room temperature, and then washed three times with PBS. To determine intracellular fluorescence and receptor internalization, the plasma membrane was delineated using the differential interference contrast image, and fluorescence in such an area was excluded; intracellular fluorescence was quantified employing ImageJ software [40–42]. To determine membrane-receptor colocalization additional experiments were performed using Alexa Fluor-350-conjugated wheat germ agglutinin (20 μg/ml) for membrane labeling. To determine the colocalization of the α_{1D}-AR with β-arrestin 1/2, the cells were fixed, as indicated previously, and samples were permeabilized with 0.3% Triton X-100 for 15 min at 4 °C. The samples were then incubated with 3% BSA for 1.5 h at room temperature, in the absence or presence of the anti-β-arrestin 1/2 antibody (1:200) with 3% BSA in 50 mM Tris base-buffered saline (pH 7.4) containing 0.1% Tween 20. After this process, the samples were washed twice, were incubated for 2 h in the same buffer containing a tetramethyl-rhodamine-conjugated secondary antibody (1500) and then washed with PBS with soft agitation. Confocal microscopy images were acquired with an Olympus Fluoview FV10 with an oil-immersion objective (60× at 5.0 zoom), 2.0 confocal aperture X16 quality high, and 512 × 512 size. To determine α_{1D}-AR/β-arrestin 1/2 colocalization, the overlap of the two fluorophores (EGFP/rhodamine) was estimated employing ImageJ software [40–42]. Representative images showing green channel fluorescence, red channel

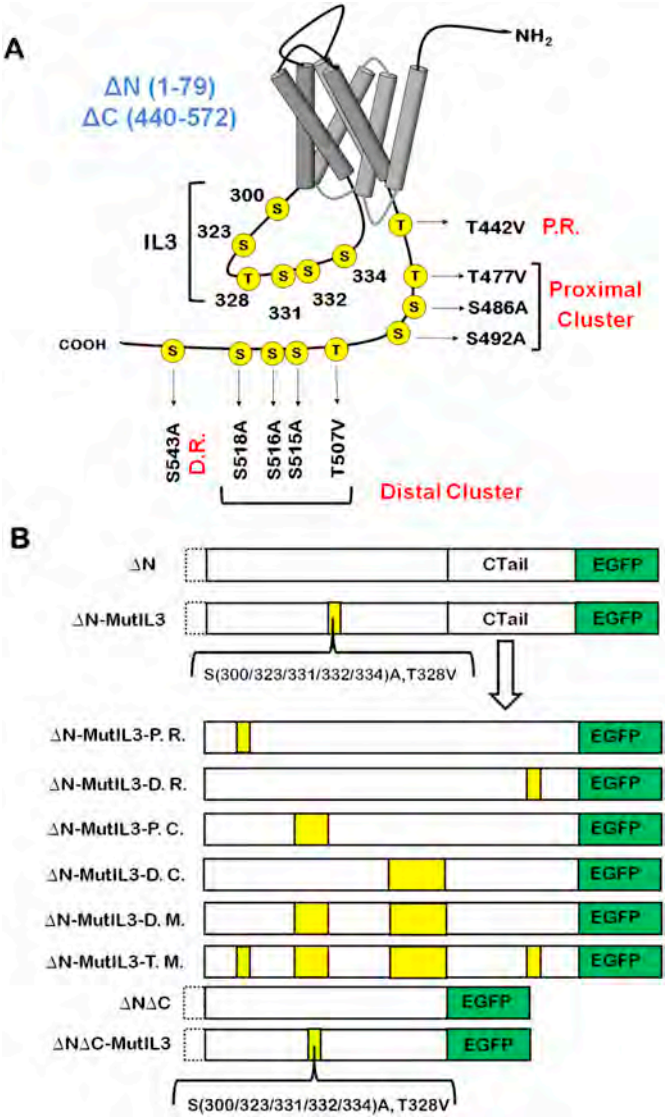

Fig. 1. Schematic representation of the α_{1D}-AR mutants. Panel A: The phosphorylation residues of the α_{1D}-AR detected by MS analysis are located in the IL3 and in the C-terminal tail. Such residues were mutagenized to non-phosphorylatable amino acids: serine residues changed into alanine and threonine residues changed into valine. Panel B: Schematic representation of the α_{1D}-AR mutants. Dotted lines in the constructs represent the deletion of the first 79 amino acids of the N-terminal region (ΔN, 1–79). The mutant ΔN-MutIL3 was generated taking the ΔN receptor as a template. Yellow section in this mutant indicates that the residues S300, S323, S331, S332, S334 and T328 located in the IL3, were mutagenized by non-phosphorylatable residues, as previously described. Subsequently, the ΔN-MutIL3 mutant was mutagenized in T442 (ΔN-MutIL3-P.R.), S543 (ΔN-MutIL3-D.R.), T477, S486, S492 (ΔN-MutIL3-P.C., proximal cluster), T507, S515, S516, and S518 (ΔN-MutIL3-D.C., distal cluster), T477, S486, S492, T507, S515, S516, and S518 (ΔN-MutIL3-D.M.) and T442, T477, S486, S492, T507, S515, S516, S518, and S543 (ΔN-MutIL3-T.M.). Deletion of the last amino acids (440–572) in the CTail (ΔN).

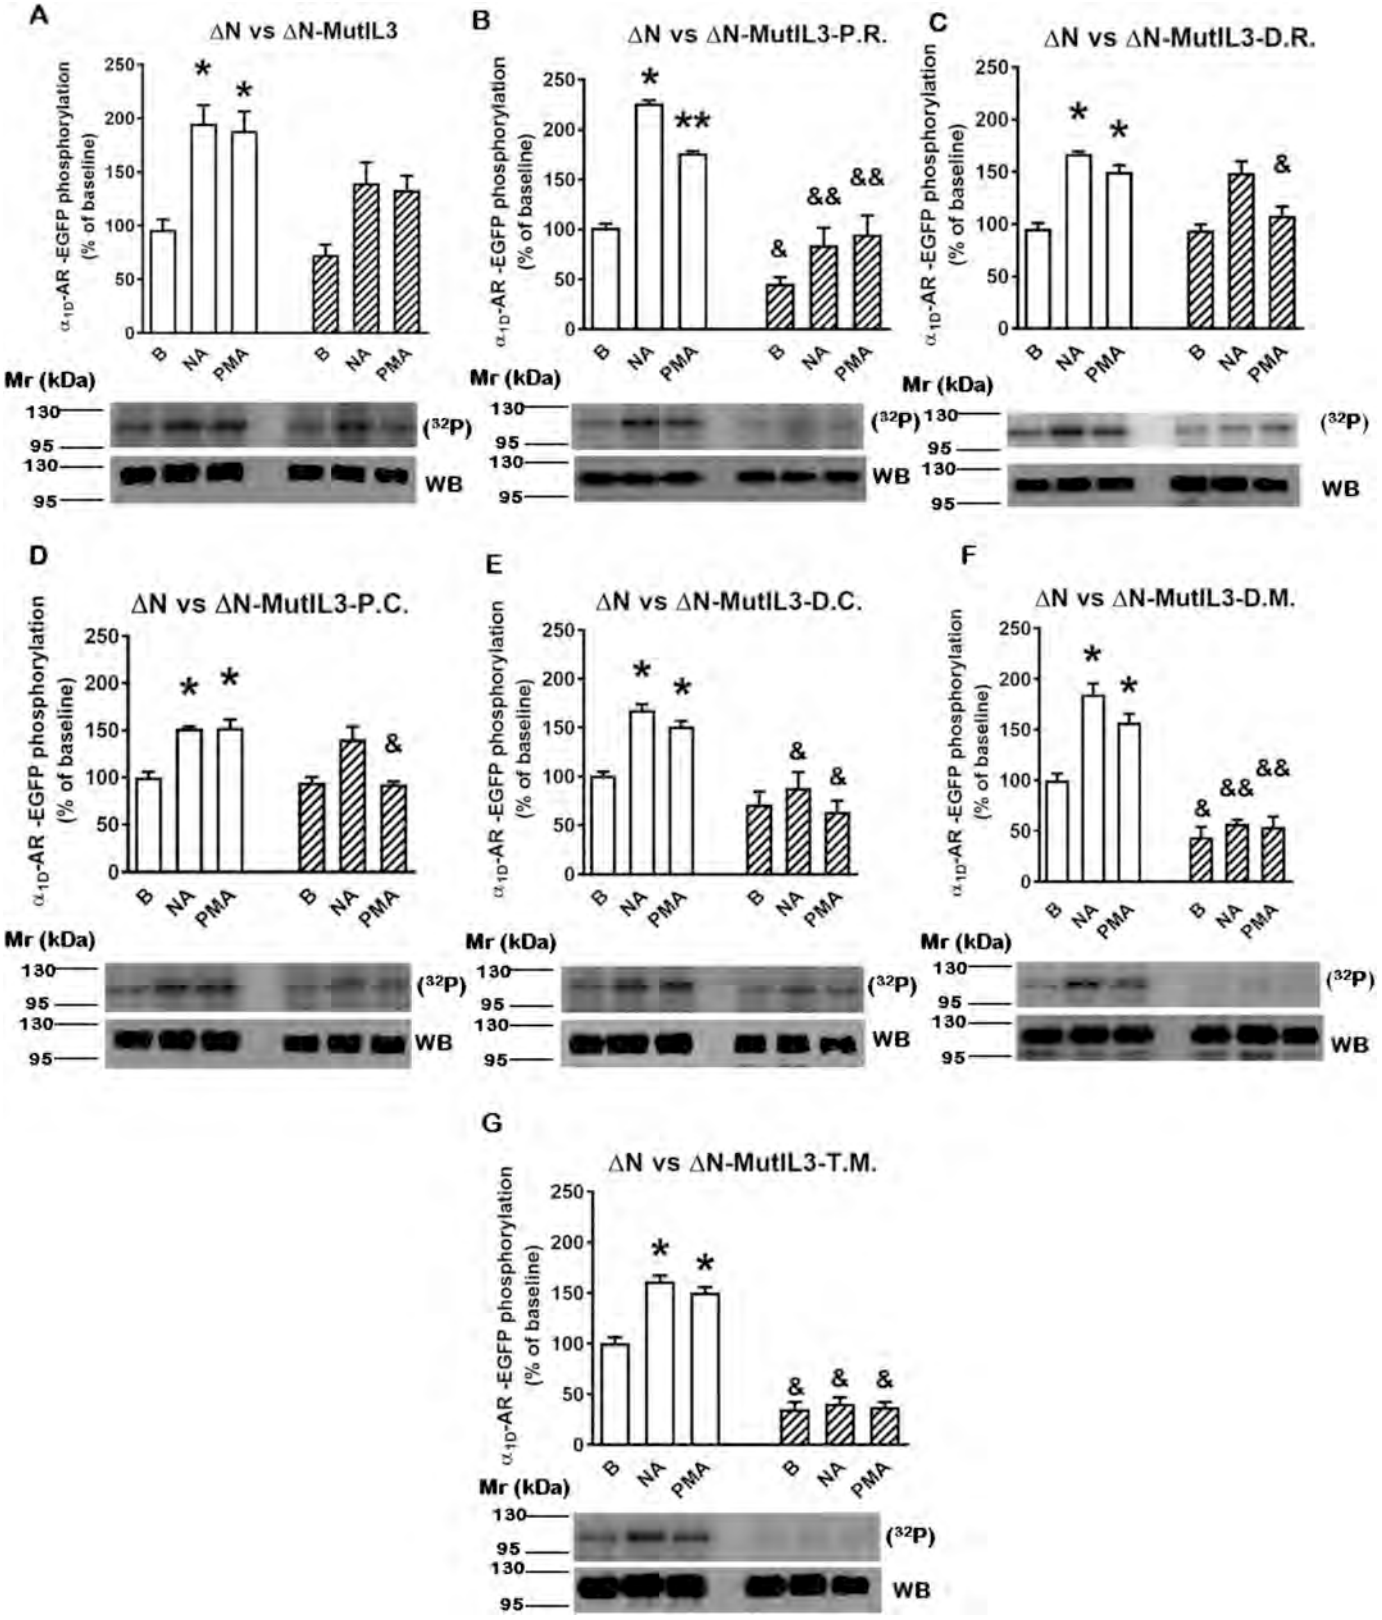

Fig. 2. NA-and PMA-induced phosphorylation of the different α_{1D}-AR mutants. Cells expressing the different constructs were stimulated with NA 10 μM and PMA 1 μM for 15 min and compared to the ΔN receptor. In all cases, cultures were processed in parallel and data were normalized to the percentage of the ΔN receptor's baseline (B) phosphorylation. Plotted lines are the means and vertical lines representing S.E.M. of 3–5 independent experiments. Representative autoradiographs and Western-blots are presented below each graph. Panel 2A, * $P < 0.005$ vs. ΔN receptor's baseline; Panel 2B, *$P < 0.001$ vs, ΔN receptor's baseline, ** $P < 0.005$ vs. ΔN receptor's baseline, & $P < 0.05$ vs. ΔN receptor's baseline, && $P < 0.001$ vs. ΔN receptor's corresponding stimulus; Panel 2C, * $P < 0.001$ vs. ΔN receptor's baseline, & $P < 0.01$ vs. ΔN receptor's PMA; Panel 2D, * $P < 0.005$ vs. ΔN receptor's baseline, & $P < 0.005$ vs. ΔN receptor's PMA; Panel 2E, * $P < 0.005$ vs. ΔN receptor's baseline, & $P < 0.001$ vs. ΔN receptor's corresponding stimulus; Panel 2F, * $P < .005$ vs. ΔN receptor's baseline, & $P < 0.005$ vs. ΔN receptor's baseline, && $P < 0.001$ vs. ΔN receptor's corresponding stimulus; Panel 2G, * $P < 0.001$ vs. ΔN receptor's baseline, & $P < 0.001$ vs. ΔN receptor's corresponding condition.

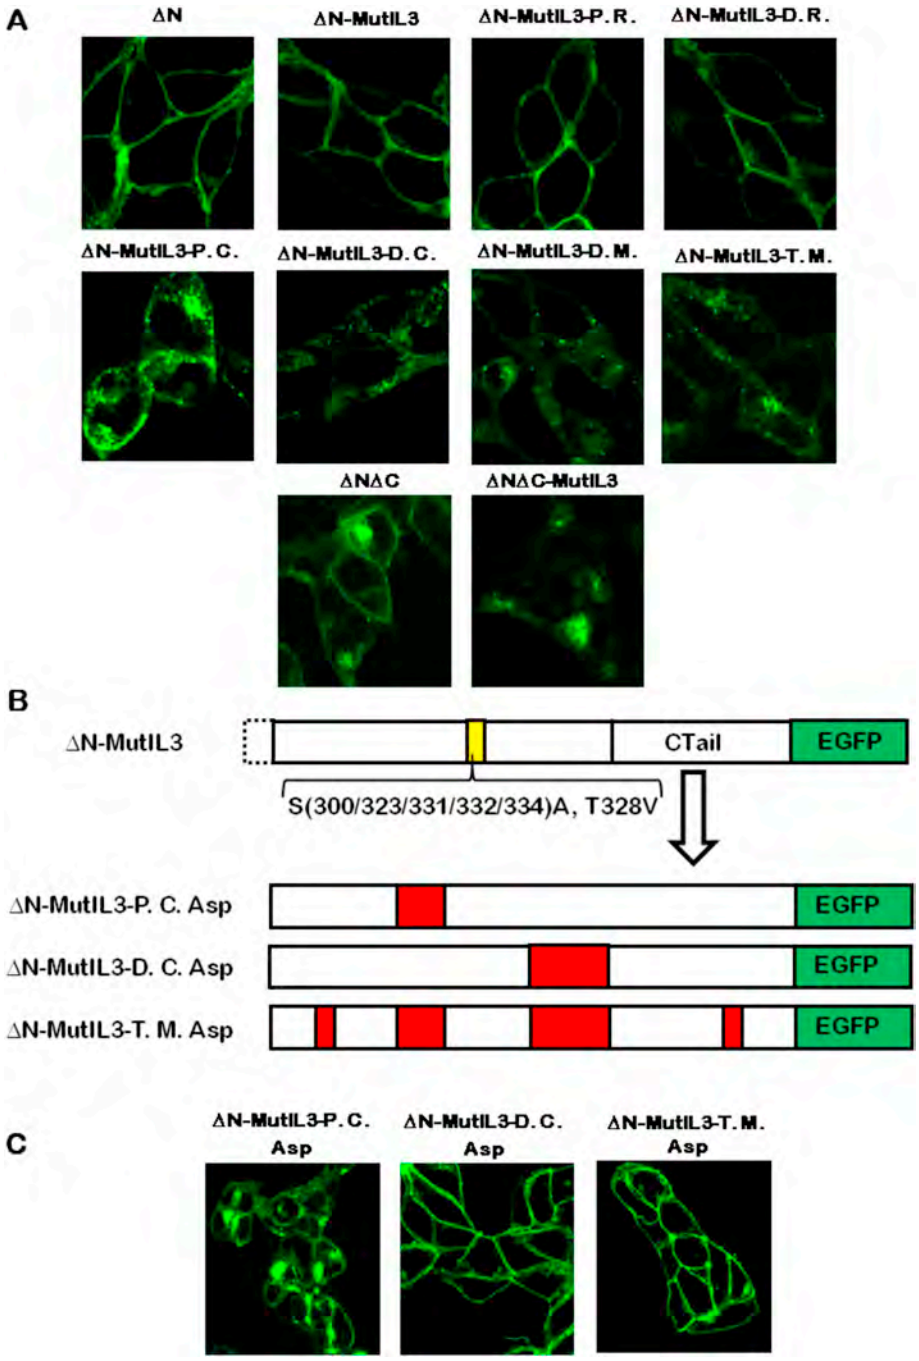

Fig. 3. Subcellular localization of α_{1D}-AR mutants under baseline conditions and schematic representation of the mutants with aspartic acid. Panel A: Cells expressing the different constructs of α_{1D}-AR were analyzed under baseline conditions by confocal microscopy. Images are representative of data of 5–7 experiments using different cell preparations. Panel B: ΔN-MutIL3 was used as a template to change the residues located in the proximal (ΔN-MutIL3-P.C. Asp), and distal cluster (ΔN-MutIL3-D.C. Asp) as well as in both clusters and both proximal and distal residues (ΔN-MutIL3-T.M. Asp), by aspartic acid (phospho-mimetic). Red sections in the constructs represent these mutations. Panel C: ΔN-MutIL3-P.C. Asp, ΔN-MutIL3-D.C. Asp, and ΔN-MutIL3-T.M. Asp mutants were analyzed under baseline conditions by confocal microscopy. Images are representative of data of 5–7 experiments using different cell preparations.

fluorescence, merged images, and pixel-by-pixel colocalization are presented. At least 10 different images per condition were obtained for each experiment.

2.8. Statistical analyses

Statistical comparisons between two conditions was performed employing the Student's *t*-test (Figures 7 and 20; indicated in the text). All other statistical analysis (comparisons between groups with three or more variables) were evaluated using a parametric analysis of variance (ANOVA) with Bonferroni's post-test, assuming Gaussian data distribution (http://www.graphpad.com/guides/prism/7/statistics/index.htm). We utilized the software included in GraphPad Prism 6 software to perform these analyses. A P value < 0.05 was considered statistically significant.

3. Results

3.1. α_{1D}-AR phosphorylation sites and site-directed mutagenesis

Using mass spectrometry, we previously reported that α_{1D}-AR harbors six phosphorylated residues (S300, S323, T328, S331, S332, and S334) in IL3 and nine more on the CTail (see below) [22]. One of the main goals of the present work was to experimentally define the role(s) of the CTail phosphorylation residues. To accomplish this, first we identified that phosphorylation sites in the CTail have a particular arrangement, i.e., two isolated residues (T442 and S543) and two groups of residues with close proximity; we named these groups as proximal cluster (T477, S486, S492) and distal cluster (T507, S515, S516, S518) (Fig. 1A).Taking this arrangement into account, we generated a combination of point mutations and deletions on the α_{1D}-AR (Fig. 1B). As

INFORME DE LABORES 2019

already mentioned, the α_{1D}-AR amino terminus negatively controls its membrane-targeting [7,8,21–24]. Therefore, all of the mutants were designed using the amino-truncated receptor (ΔN; abbreviated names will be used for clarity). Non-phosphorylatable substitutions in the six residues in IL3 (ΔN-MutIL3) were obtained. These two modifications represent a compromise necessary to obtain: a) membrane expression and b) to eliminate the contribution of phosphorylation at the IL3 in our studies. Then, we used this latter mutant as a template to further individually mutagenize the proximal residue T442 V (ΔN-MutIL3-P.R.) and the distal residue S543A (ΔN-MutIL3-D.R.), as well as the proximal and distal clusters (ΔN-MutIL3-P.C. and ΔN-MutIL3-D.C., respectively). We also included a double mutant where both clusters were changed (ΔN-MutIL3-D.M.) and a total mutant (ΔN-MutIL3-T.M.), including all of these substitutions in the CTail. Finally, we employed the previously reported carboxyl tail-truncated receptor (ΔNΔC) [22] and a further mutated form in which IL3 phosphorylated residues were changed into non-phosphorylatable amino acids (ΔNΔC-MutIL3) [22]. All of these mutants were tagged with EGFP for confocal microscopy imaging and biochemical studies.

Next we utilized Flp-In T-Rex HEK293 cells expressing the former mutants to asses receptor phosphorylation during homologous and heterologous desensitization, i.e., in the presence of 10 μM NA or 1 μM PMA for 15 min. Agents, concentrations, and incubation times were selected based on previously reported data [22]. In independent parallel experiments, the phosphorylation of the ΔN receptor was compared with each of the other mutants and all data were normalized to the phosphorylation of the ΔN receptor detected under baseline conditions. ΔN receptor baseline phosphorylation increased approximately 2-fold after stimulation with NA and PMA, as illustrated in Fig. 2A. In cells expressing the ΔN-MutIL3 receptor, baseline phosphorylation and the actions of NA and PMA were marginally decreased when compared to those of the ΔN receptor (not statistically significant). The CTail mutation on the proximal residue (ΔN-MutIL3-P.R.), resulted in a receptor with decreased baseline labeling and phosphorylation in response to NA and PMA (Fig. 2B). On the other hand, the mutant receptor with the non-phosphorylatable distal residue (ΔN-MutIL3-D.R.) did not exhibit any clear difference in baseline or NA-induced phosphorylation when compared with the ΔN mutant, but the effect of PMA was reduced (Fig. 2C). Similarly, the proximal cluster mutant (ΔN-MutIL3-P.C.) increased its phosphorylation in response to NA, but not after PMA stimulation (Fig. 2D). Interestingly, the receptor with the mutated distal cluster, ΔN-MutIL3-D.C., showed a slight decrease in basal phosphorylation but marked attenuation of phosphorylation observed in response to NA or PMA (Fig. 2E). Baseline phosphorylation of the receptor containing the double-cluster mutations (ΔN-MutIL3-D.M.) diminished below ΔN baseline levels and nearly no effect of NA or PMA was detected (Fig. 2F). Very similar results were obtained with the total mutant (ΔN-MutIL3-T.M.) (Fig. 2G). Overall, these data experimentally confirmed that α_{1D}-AR phosphorylation specifically occurs at the residues depicted in Fig. 1A. It appears that phosphorylatable residues in proximal and distal clusters and distal residue, S543, might be phosphorylated during PMA-induced desensitization and that mutations in the distal cluster also disturb NA-induced phosphorylation. Phosphorylation of ΔNΔC and ΔN-MutIL3-ΔC mutants was reported previously [22].

3.2. α_{1D}-AR plasma membrane localization is regulated by CTail distal cluster phosphorylation

Cells expressing the α_{1D}-AR mutants described previously were studied using confocal microscopy. Under baseline conditions, we observed that the control receptor (ΔN) and the mutant containing substitutions in the IL3 (ΔN-MutIL3), as well as receptors additionally containing single mutations in the proximal and distal residues (ΔN-MutIL3-P.R. and ΔN-MutIL3-D.R., respectively) were mainly located at the plasma membrane. In contrast, receptors including non-phosphorylatable substitutions in the CTail proximal or distal clusters were found mainly in vesicles (Fig. 3A). Prompted by this observation, we measured intracellular fluorescence to qualitatively determine the main subcellular location of each mutant. As depicted in Fig. 4, we normalized all data to the signal detected in the control receptor (ΔN), i. e., it was considered as 100%. As Fig. 4 illustrates, we detected some intracellular fluorescence in ΔN, ΔN-MutIL3, ΔN-MutIL3-P.R. and in ΔN-MutIL3-D.R., whereas the following mutants showed approximately a 4-fold increment of fluorescence located intracellularly: ΔN-MutIL3-P.C., ΔN-MutIL3-D.C., ΔN-MutIL3-D.M. and ΔN-MutIL3-T.M. Moreover, the carboxyl truncated mutants (ΔNΔC and ΔNΔC-MutIL3) revealed a 6-fold increase of intracellular fluorescence. In other words, truncation of the entire CTail or substitutions in the phosphorylation clusters contained in this domain blocked the receptor's ability to reach or remain at the plasma membrane.

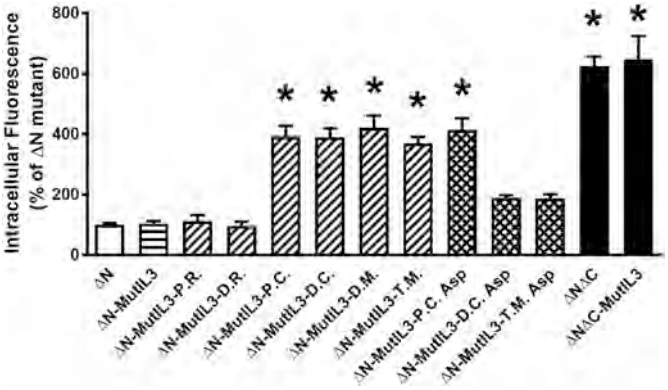

Fig. 4. Intracellular fluorescence quantification (α_{1D}-AR mutants) under baseline conditions. Accumulation of intracellular fluorescence under baseline conditions was quantified for α_{1D}-AR mutants. Data were normalized to that observed in cells expressing the ΔN mutant (100%). Plotted lines are the means and vertical lines representing S.E.M. of 7 independent experiments in each of which 3–5 cells were analyzed (n = 20–35). * $P < 0.001$ vs ΔN.

Under the latter premise, we hypothesized that phosphorylation of such residues in close proximity might regulate receptor subcellular localization. In order to test this, we generated phospho-mimetic mutants containing aspartic acid substitutions. As presented in Fig. 3B, the phosphorylatable residues were changed to aspartic acid in the proximal (ΔN-MutIL3-P.C. Asp) and distal clusters (ΔN-MutIL3-D.C. Asp), as well as in both clusters plus the isolated residues, to generate a total phospho-mimetic mutant (ΔN-MutIL3-T.M. Asp). We observed abundant vesicles in cells expressing ΔN-MutIL3-P.C. Asp (Fig. 3C). This mutant also showed a 4-fold increment of intracellular fluorescence, similar to the mutants lacking phosphorylation clusters (Fig. 4). Surprisingly, ΔN-MutIL3-D.C. Asp and ΔN-MutIL3-T.M. Asp mutants were fully expressed at the plasma membrane (Fig. 3C) and they both showed intracellular fluorescence levels equivalent to the control (intracellular fluorescence quantifications are presented in Fig. 4). In order to confirm these results, colocalization experiments employing Alexa Fluor-350-conjugated wheat germ agglutinin were performed with six of the mutants employed (ΔN, ΔN-MutIL3, ΔN-MutIL3-D.C., ΔN-MutIL3-T.M., ΔN-MutIL3-D.C. Asp and ΔN-MutIL3-T.M. Asp). Wheat germ agglutinin is generally considered as a membrane marker but also binds to glycoproteins present in other organelles [43]. Observations were normalized to the colocalization observed with cells expressing the ΔN mutant. As shown in Fig. 5, in non-permeabilized cells, the lectin labeled the plasma membrane but also some structures present inside the cells; this was much more clearly observed in cells containing large amounts of vesicles. Despite this, the colocalization data (Fig. 5) confirmed the previous findings (Fig. 4). Altogether, these results suggest that, specifically, distal-cluster phosphorylation could be necessary and sufficient to allow α_{1D}-AR plasma membrane localization.

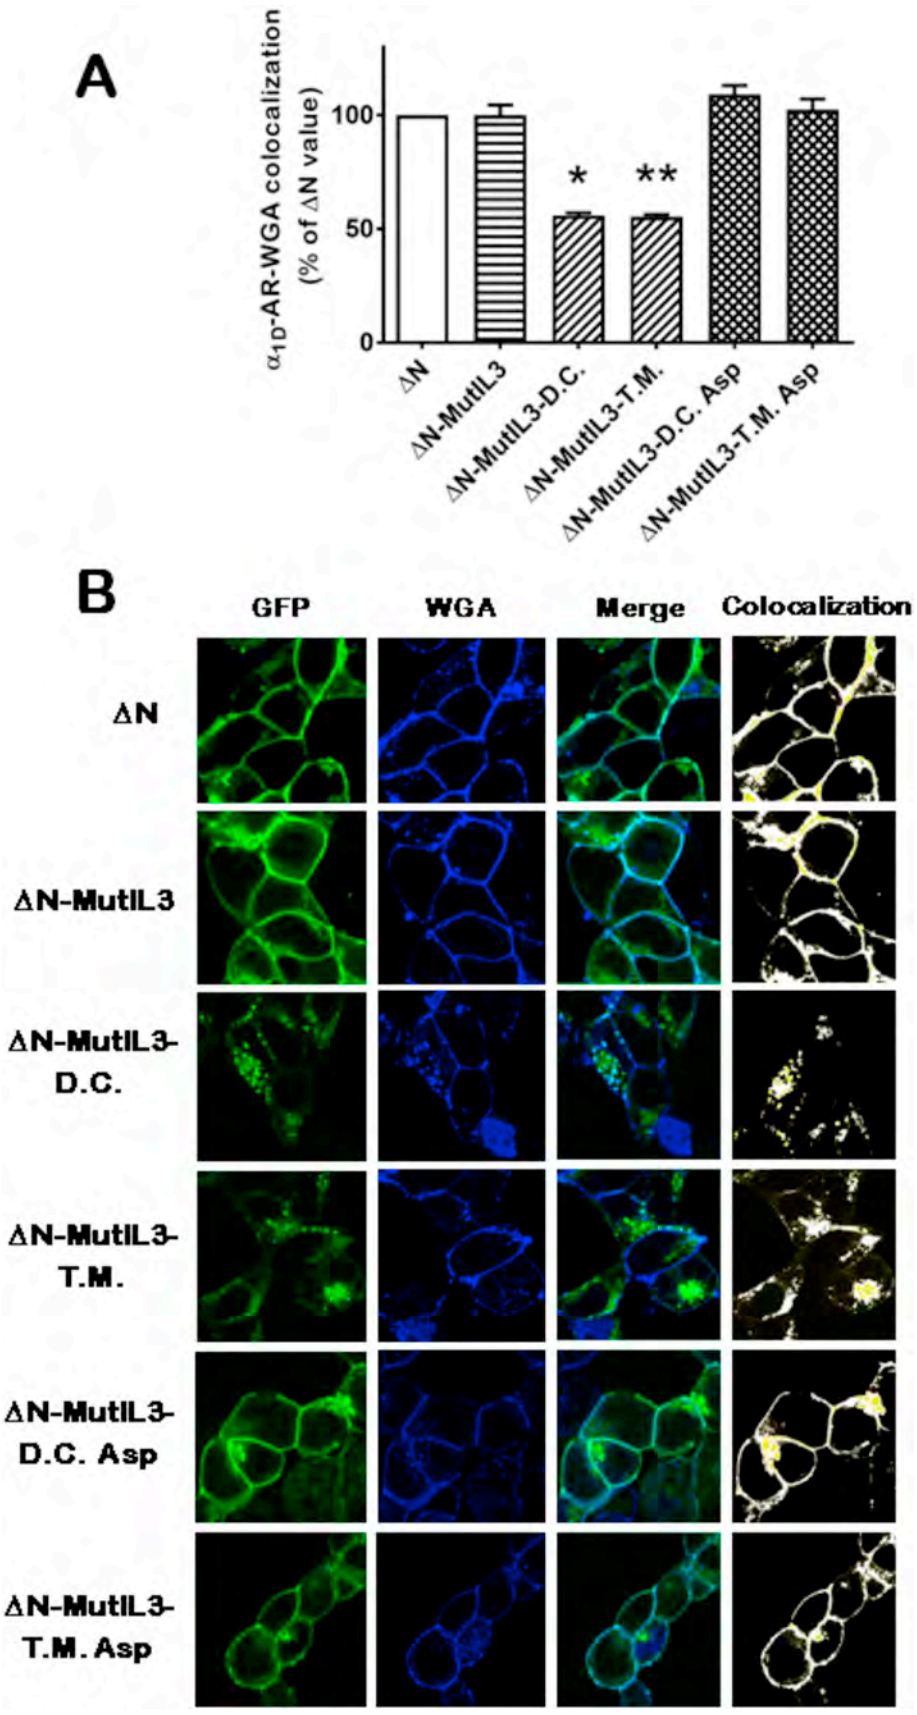

Fig. 5. Colocalization of α_{1D}-AR mutants with Alexa Fluor-350-conjugated wheat germ agglutinin (plasma membrane marker) under baseline conditions. Cells expressing the different constructs of α_{1D}-AR were fixed and stained with Alexa Fluor-350-conjugated wheat germ agglutinin (WGA), as indicated under Material and Methods. Fluorescence was analyzed under baseline conditions by confocal microscopy and ImageJ analysis. Panel A, Receptor-membrane marker colocalization, normalized to ΔN mutant baseline value (100%), is presented. Plotted are the means and vertical lines representing S.E.M. of 4 independent experiments in each of which 10 cells were analyzed ($n = 40$). * $P < 0.001$ vs. ΔN mutant and $P < 0.001$ vs. ΔN-MutIL3-D.C. Asp; ** $P < 0.001$ vs. ΔN mutant and $P < 0.001$ vs. ΔN-MutIL3-T.M. Asp. Panel B, representative images showing: receptor fluorescence (GFP), WGA fluorescence, Merge images and colocalization (white).

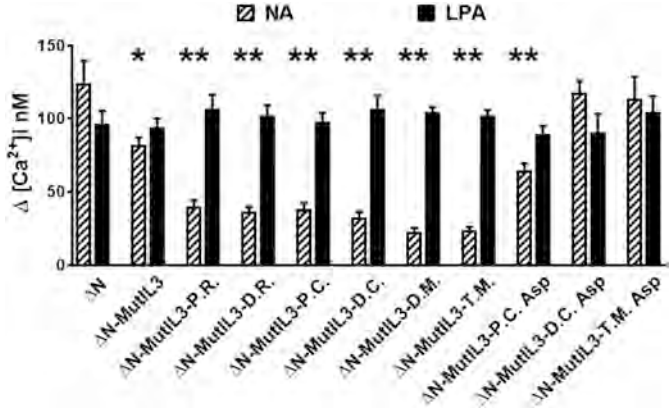

Fig. 6. NA- and LPA-induced mobilization of intracellular calcium in cells expressing the different α_{1D}-AR mutants. Cells expressing the different constructs were stimulated with NA 10 μM (dashed bars) or LPA 1 μM (solid bars) and increases (Δ $[Ca^{2+}]$ i nM; baseline subtracted) in intracellular calcium concentration were determined. Plotted are the means and vertical lines representing S.E.M. of 5–7 independent experiments. * $P < 0.005$ vs. ΔN, NA-stimulation; * $P < 0.001$ vs. ΔN, NA-stimulation. No significant difference was observed when the response to LPA stimulation in the different cell lines was compared.

3.3. Phosphorylation on α_{1D}-AR CTail specific residues regulates the mobilization of intracellular Ca^{2++}

Next, we evaluated agonist-induced mobilization of intracellular calcium to determine the functionality of the receptors previously described. As depicted in Figs. 6, 10 μM NA elicited an increase of over 100 nM intracellular calcium in cells expressing the ΔN receptor, whereas it scarcely reached 100 nM in cells expressing the ΔN-MutIL3 mutant. Remarkably, in CTail mutants lacking phosphorylatable single residues or clusters (ΔN-MutIL3-P.R., ΔN-MutIL3-D.R., ΔN-MutIL3-P.C., and ΔN-MutIL3-D.C.), calcium release was markedly reduced as compared with those expressing the ΔN receptor. Calcium increments were even smaller in double and total mutants (ΔN-MutIL3-D.M. and ΔN-MutIL3-T.M.). As a positive control, we measured the response of endogenously expressed lysophosphatidic acid receptors, using 1 μM LPA, and a consistent increase in calcium concentration (≈ 100 nM) was observed in cells expressing the different mutants. When we examined receptors containing the phospho-mimetic mutations, we observed that the proximal cluster mutant (ΔN-MutIL3-P.C. Asp) partially recovered its ability to mobilize intracellular calcium. Interestingly, distal cluster and total mutants containing the phospho-mimetic mutations (ΔN-MutIL3-D.C. Asp and ΔN-MutIL3-T.M. Asp) were able to increase calcium to concentrations similar to those of the control (ΔN receptor-expressing cells). These data suggest that phosphorylation of the CTail region, mainly at the distal cluster, controls the ability of α_{1D}-AR to trigger the calcium signaling pathway. NA-induced increases in intracellular calcium in cells expressing the ΔNΔC and ΔN-MutIL3-ΔC mutants were reported previously [22]. The effect of NA on intracellular calcium concentration as affected by NA, PMA and BMY 7378 (inverse agonist) [10,11,24] is presented in Supplementary Fig. S1. In agreement with the previous data, NA action was robust in cells expressing the ΔN mutant; this was of smaller magnitude in cells expressing the ΔN-MutIL3 mutant and even smaller in cells expressing the ΔN-MutIL3-T.M. receptors. Similarly, the ability of PMA and BMY 7378 was very clear in cells expressing the ΔN mutant and marginal (but statistically significant) in cells expressing the total mutant (Supplementary Fig. S1).

3.4. α_{1D}-AR mutants' ERK activation kinetics

A different pathway initiated by α_{1D}-AR was investigated. ERK 1/2 phosphorylation was determined under baseline conditions and after 2, 5, 15, 30, and 60 min of incubation with 10 μM noradrenaline. As it is shown in Fig. 7A, the ΔN mutant showed a rapid increase in ERK phosphorylation after 5 and 15 min, and subsequently, this signal decreased at 30 and 60 min. In the same way, the rest of the mutants also presented a quick increase in ERK 1/2 phosphorylation. However, the signal remained elevated in all of these even after 60 min of observation (this trend was statistically significant (Student's *t*-test $P < 0.05$; 60 min vs. ΔN mutant) except for the ΔN-MutIL3-D.R. and ΔN-MutIL3-D.M. mutants). Representative Western blots of the p-ERK 1/2 and total-ERK 1/2 of each mutant are presented (Fig. 7B).

3.5. α_{1D}-AR activation of ERK is regulated by the transactivation of the EGF receptor and β-arrestins

It has been observed that α_{1D}-AR activation induces the shedding of active epidermal growth factor (EGF) that stimulates the EGF receptor and contributes to the activation of ERK 1/2 [44]. Fig. 8A shows that when cells expressing the ΔN receptor are treated with EGF, a robust increase in ERK 1/2 phosphorylation can be detected. AG1478, a specific inhibitor of EGF receptor endogenous tyrosine kinase activity [45] totally abolished the EGF effect. Cells stimulated with NA for 5 min, also showed an important increase in ERK 1/2 phosphorylation; interestingly, this activation was markedly diminished when the cells were pre-incubated with AG1478 and then challenged with NA (Fig. 8A). It has been shown that activation of ERK depends in some cells on the binding of β-arrestins to GPCRs, forming a multi-protein complex: GPCR/β-arrestin/ERK1/2 [32]. In order to explore the possible participation of β-arrestins, we knocked down the expression of β-arrestin 1/2 by using small interfering RNA. Fig. 8B illustrates the increase in ERK 1/2 phosphorylation when cells expressing the ΔN mutant were stimulated with NA for 5 and 60 min. Scrambled small interfering RNA induced a very small decrease (not statistically significant) of NA-induced ERK phosphorylation, as presented in the same figure. In contrast, when β-arrestin1/2 was knocked down, a clear decrease of NA-induced ERK phosphorylation was detected, at 5 and 60 min. β-arrestin 1/2 knock down was confirmed by Western blot analysis (Fig. 8B). The roles of EGF receptor transactivation and of β-arrestin 1/2 knock down were also tested in cells expressing the ΔN-MutIL3-T. M. mutant and the results were very similar, i. e., data confirmed the role of these processes in α_{1D}-AR ERK 1/2 activation (Supplementary Fig. S2). Overall, these experiments suggest that transactivation of EGF receptors and β-arrestins participate in NA-induced ERK 1/2 activation, in cells expressing the receptor mutants employed.

3.6. The α_{1D}-AR mutants have a different kinetic of internalization triggered by NA and PMA

α_{1D}-AR internalization using confocal microscopy was studied next. In order to achieve this, we exclusively studied the mutants that were mainly expressed at the plasma membrane under baseline conditions. Attempts to study this with mutants that were mainly internalized proved to be impossible with this approach. To evaluate the kinetic profiles of internalization, cells were stimulated with NA or PMA. The intracellular fluoresce of cells expressing each mutant, under baseline conditions, was considered as 100% (Figs. 9 and 10); these baseline values were very similar as shown in Fig. 4. As depicted in Fig. 9A, we stimulated the cells with NA 10 μM and detected an increase in the intracellular florescence at 5 and 15 min in the ΔN mutant. Subsequently, the intracellular signal vanished and was barely detected at 30

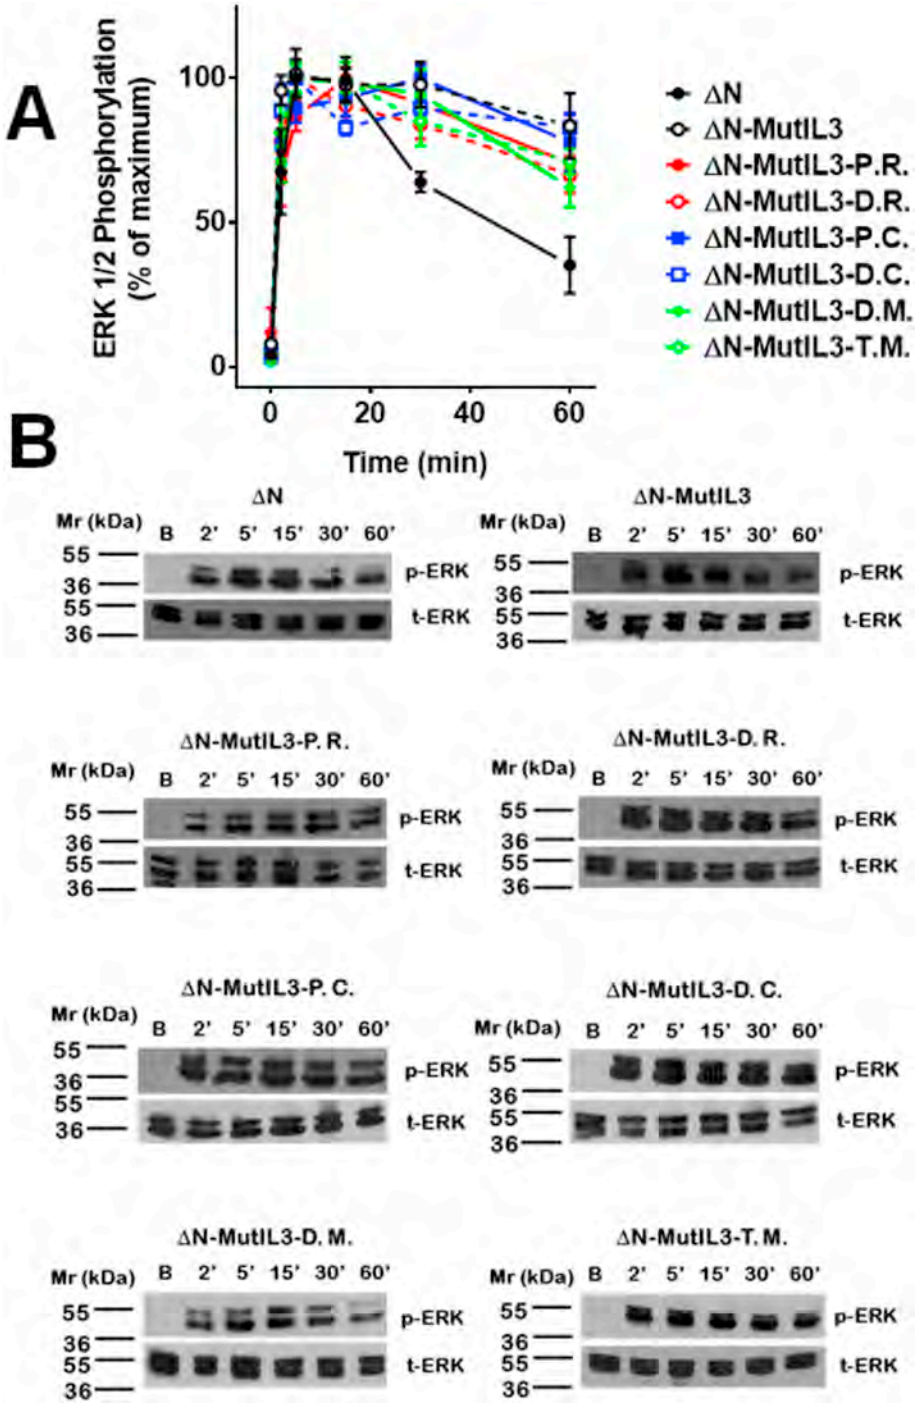

Fig. 7. Time-course of NA-induced activation of ERK1/2 in the different α_{1D}-AR mutants. Cells expressing the different constructs were stimulated for the times indicated with NA 10 μM, and ERK1/2 phosphorylation was determined. Plotted lines are the means and vertical lines representing S.E.M. of at least 4 independent experiments. Representative Western-blots for total-ERK1/2 and phospho-ERK1/2 are presented below the graph.

and 60 min. The ΔN-MutIL3 mutant was also internalized in response to NA, but remained so, along the 60 min of stimulation (Student's *t*-test vs. the ΔN mutant, $P < 0.001$at 60 min). Interestingly, the ΔN-MutIL3-P.R. and ΔN-MutIL3-D.R. mutants behaved in a similar manner to those of the ΔN mutant, i.e., there was an increase in intracellular fluorescence at 5 and 15 min and a partial decrease of such a signal at 30 and 60 min (Student's t-test: $P < 0.001$ vs. the ΔN mutant and $P < 0.001$ vs. the ΔN-MutIL3 mutant at 60 min). Fig. 9B presents the images of the kinetic profiles of internalization of each α_{1D}-AR mutant.

Next, we decided to evaluate the kinetic profile of internalization of the same mutants by stimulating the cells with 1 μM PMA. As shown in Fig. 10A, we detected that the ΔN mutant progressively internalized during the 60 min of incubation. In contrast, the ΔN-MutIL3 reached the maximal internalization at 15 min and then intracellular fluorescence

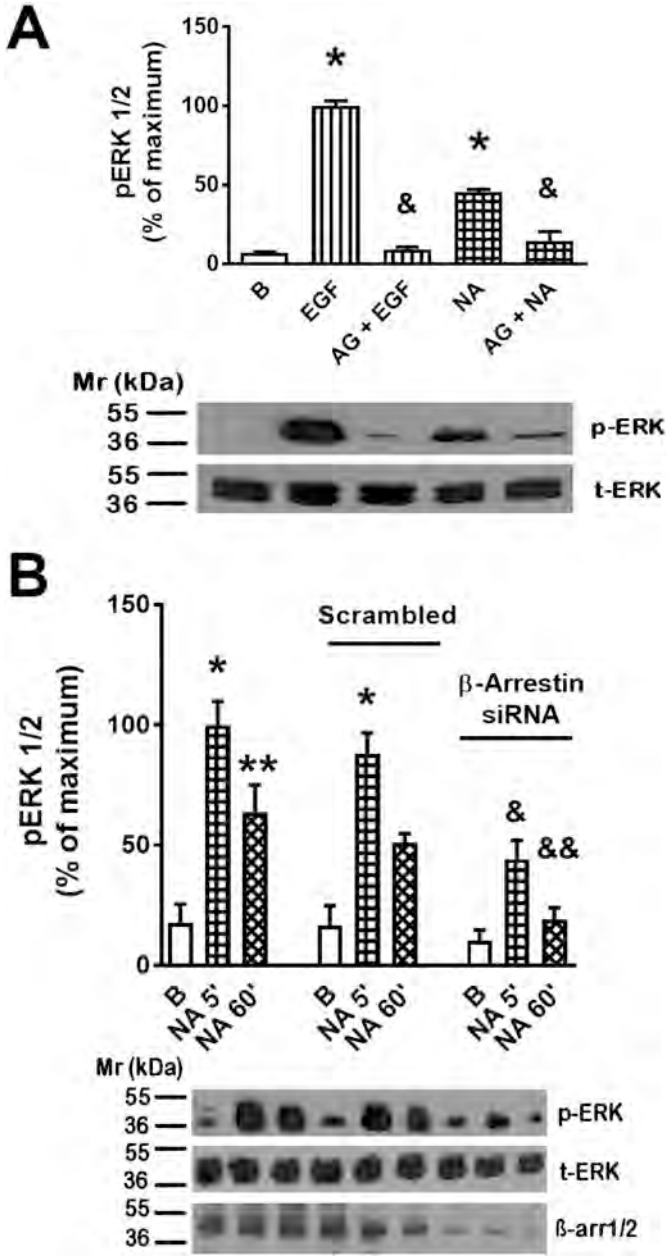

Fig. 8. Regulation of ERK 1/2 phosphorylation by EGF receptor transactivation and β-arrestins in cells expressing the ΔN receptor. Panel A: Cells were pre-incubated in the absence or presence of AG1478 10 μM (AG) and then challenged with EGF 100 ng/ml or NA 10 μM for 5 min. Plotted are the means and vertical lines representing the S.E.M. of 3 independent experiments. * $P < 0.001$ vs. baseline (B); & $P < 0.001$ vs. absence of AG1478. Representative Western-blots for total-ERK 1/2 and phospho-ERK 1/2 are presented below the histogram. Panel B: Cells were nor transfected (first group or bars), or they were transfected with either a scrambled siRNA (second group of bars) or with a specific siRNAs to block the expression of β-arrestin 1/2 (third group of bars) Cells were stimulated with NA 10 μM for 5 (5′) or 60 min (60′). Plotted are the means and vertical lines representing S.E.M. of 3 independent experiments. * $P < 0.001$ vs. respective baseline (B); ** $P < 0.05$ vs. respective baseline (B); & $P < 0.005$ vs NA 5′ non-transfected cells and $P < 0.05$ vs. NA 5′ scrambled siRNA; && $P < 0.05$ vs. NA 60′ non-transfected cells. Representative Western-blots for total-ERK 1/2, phospho-ERK 1/2, and β-arrestins (β-arr1/2) are presented below the histogram.

gradually decreased toward baseline values (Fig. 10A, Student's *t*-test vs. the ΔN mutant, $P < 0.001$ at 60 min). The ΔN-MutIL3-P.R. similarly reached its maximal internalization at 15 min,but intracellular fluorescence remained at that level during the remaining of the incubation (Student's t-test vs. the ΔN mutant and ΔN-MutIL3 mutant, $P < 0.001$ in both comparison, at 60 min). The ΔN-MutIL3-D.R. mutant behaved like the ΔN-MutIL3 mutant (Fig. 10A, Student's t-test vs. the ΔN mutant, $P < 0.001$ at 60 min). Fig. 10B presents representative images of the kinetic profile of internalization of each α_{1D}-AR mutant under the action of PMA.

3.7. The α_{1D}-AR mutants colocalize with endogenous β-arrestin1/2

β-arrestins are scaffold proteins known to bind and participate in the internalization of ligand-activated receptors. This process allows for a GPCR to maintain signaling while internalized in endosomes in a β-arrestin-dependent fashion [29,46,47]. Hence, we examined the colocalization of endogenous β-arrestins with the α_{1D}-AR mutants that are expressed at the plasma membrane, taking into consideration the time at which each mutant was maximally internalized in response to NA or PMA. Data were normalized to the colocalization observed, under baseline conditions, in cells expressing each mutant. As it is shown in Fig. 11A, colocalization was observed under baseline conditions with all of the cells studied and mainly at the plasma membrane (Fig. 11B); this could be due to the α_{1D}-AR intrinsic activity. However, this was less clear with the ΔN-MutIL3-P.R mutant (Fig. 11B). When cells were treated with NA or PMA, the ΔN, ΔN-MutIL3 and ΔN-MutIL3-Δ-D.R. mutants increased their colocalization with endogenous β-arrestin1/2, and colocalization was also clearly observed intracellularly (Fig. 11, panels A and B). Interestingly, the ΔN-MutIL3-ΔP.R. mutant did not increase its colocalization with β-arrestins in response to NA or PMA. Representative images of the colocalization of each mutant with endogenous β-arrestin1/2, under the conditions described, are illustrated in Fig. 11B. When the primary anti-β-arrestin antibody was omitted during the immunostaining procedure, essentially no fluorescence was observed in the red channel and consequently no colocalization was detected; these data indicate that the observed fluorescence was due to detection of the anti-β-arrestin antibody and not to unspecific immunostaining by the secondary antibody (Supplementary Fig. S3). Colocalization of α_{1D}-AR and β-arrestin was absent in cells expressing receptors located in intracellular vesicles (data not shown). It must be stated that colocalization does not necessarily imply physical interaction of these proteins.

4. Discussion

α_{1D}-AR is known for being an elusive GPCR, whose expression, cellular localization, and function, as well as its roles in the development of cardiovascular diseases and other maladies, remain only partially known to date [48–51]. The ability of agonists and phorbol esters to induce α_{1D}-AR phosphorylation and the association of this process with receptor desensitization has been known for some time [22–24,26,27]. A series of α_{1D}-AR phosphorylation sites were recently defined by employing mass spectrometry [22]. This latter work revealed that there are six phosphorylated residues located in the IL3 and nine in the CTail, and that several protein kinases could putatively target such residues, including PKC α/β and GRK2. In our present experiments, we observed that as the phosphorylation sites were substituted by non-phosphorylatable amino acids, baseline phosphorylation, as well as those observed in response to receptor activation (NA) or PKC stimulation (PMA), decreased. Therefore, the identified 15 amino acids seem to be the major targets of the protein kinases involved

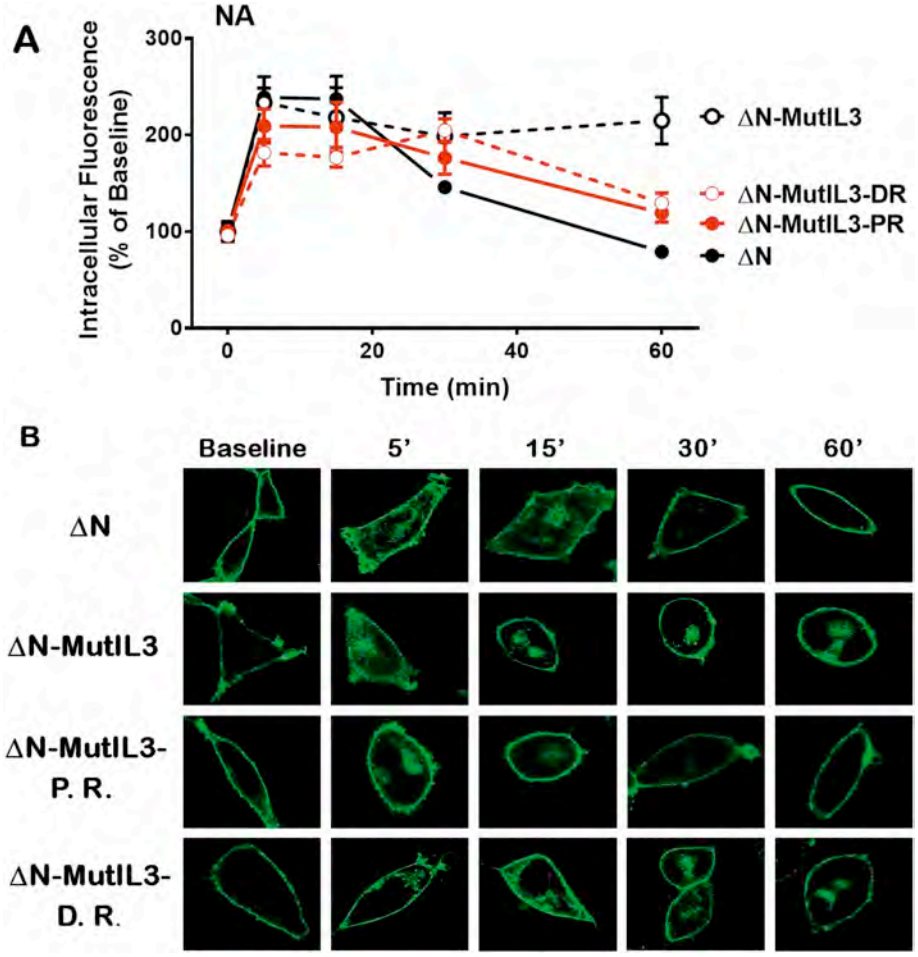

Fig. 9. Time-course of NA-induced internalization of the different α_{1D}-AR mutants. Panel A: Accumulation of intracellular fluorescence in response to NA 10 μM in cells expressing the ΔN, ΔN-MutIL3, ΔN-MutIL3-P.R. and ΔN-MutIL3-D.R. mutants. The intracellular fluorescence observed, under baseline conditions, in cells expressing each of the mutants was considered as 100%. Plotted are the means and vertical lines representing S.E.M. of 7 independent experiments in each of which 3–5 cells were analyzed (n = 20–35). Panel B: Representative images.

in α_{1D}-AR phosphorylation. However, in the total mutant, i. e. in the receptor in which all the 15 detected residues were substituted by non-phosphorylatable amino acids, a very weak but consistent receptor phosphorylation was detected, including some marginal actions of NA and PMA. It is important to consider that the reported phosphorylated residues were those that were consistently detected in the different mass spectrometry analysis performed and with high probability (i. e., high Ascore value [52]) [22]. However, during the course of that study, other phosphorylation sites were detected, although not in all the analysis or with low probability value. Therefore, it is possible that the remaining phosphorylation detected could be due to such sites. It should be mentioned that in our previous experiments using the mutant, ΔNΔC-MutIL3 (in which the amino and carboxyl termini were deleted and the identified phosphorylated sites at the IL3 were substituted by non-phosphorylatable residues), we were unable to detect receptor phosphorylation and no evidence for stimulation by NA or PMA were observed [22]. These data suggest the possibility that the unidentified phosphorylation site(s) could be present at the CTail.

Interestingly, the ΔN-MutIL3-P.R. mutant in which the proximal residue, T442, was modified to valine showed a decrease in baseline as well as in stimulated (NA and PMA) receptor phosphorylation. Such decrease was much larger than could have been anticipated, because only one of the phosphorylation targets was modified. This might suggest that such a residue could be an important regulator of total receptor phosphorylation. In addition, this mutant, although mainly localized at the plasma membrane, appears to colocalize poorly with β-arrestins in response to NA or PMA. This could be related with its decreased phosphorylation, since it has been shown structurally that phosphorylation of CTail peptides is critical for β-arrestin binding [53]. However, we cannot discard the possibility that the amino acid substitution could alter the structure in such a way that both receptor phosphorylation and colocalization with β-arrestins could be perturbed. GPCR association with β-arrestins has been mainly observed during homologous desensitization and the information of such possible interaction during heterologous desensitization is scarce; our present data suggest that this takes place in the course of both processes.

We previously observed that an amino- and carboxyl-termini-truncated receptor (i. e., the ΔNΔC α_{1D}-AR mutant) was able to increase intracellular calcium (G protein signaling) and could be desensitized by PKC activation [18]. The lack of the CTail altered the mitogen activated kinase pathways in some cells (Rat-1 fibroblasts or neuroblastoma B103), but not in the HEK cell line [17]. We also observed that mutants lacking the CTail (i. e., the ΔNΔC and ΔNΔC-MutIL3 receptors) were mainly localized in intracellular vesicles [16], which was confirmed in the present work. It has been reported that the α_{1D}-AR CTail is of importance for this receptor's proper plasma membrane targeting/insertion, because interaction with proteins such as syntrophins seems to be involved and this takes place through the receptor's CTail-located PDZ domain [44,45].

One of the major findings of the present work is the relationship between phosphorylatable residues and α_{1D}-AR cellular localization. As already mentioned, current ideas indicate that GPCR phosphorylation

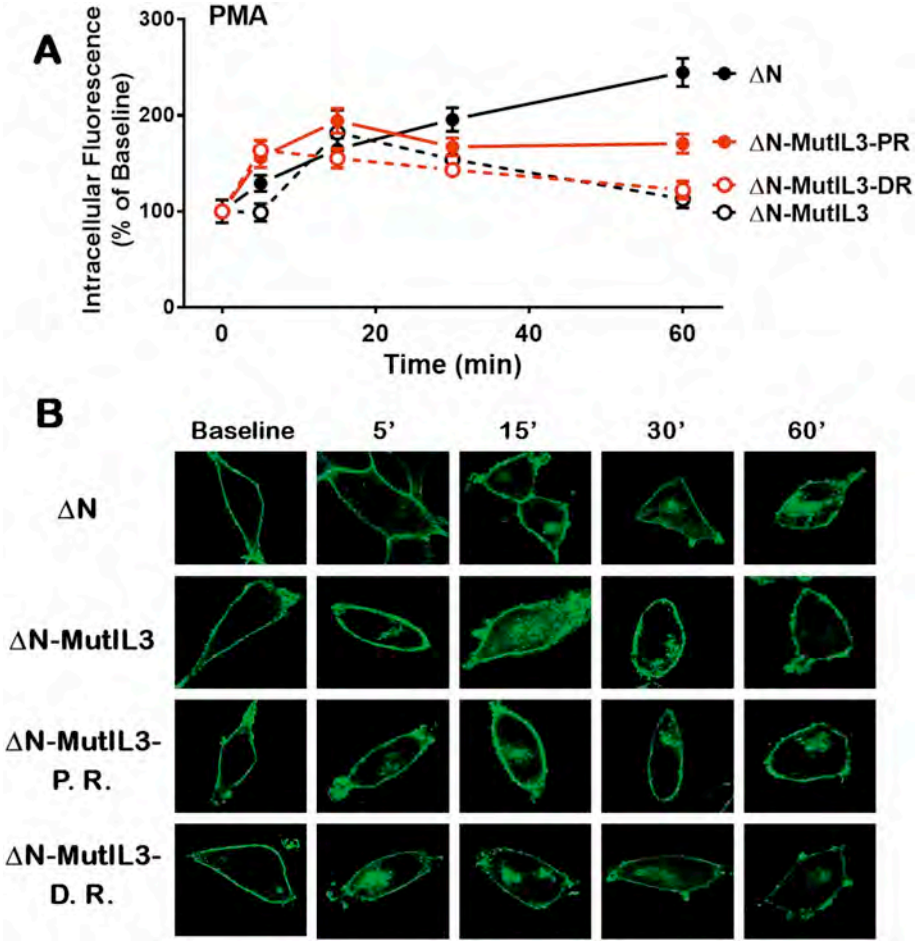

Fig. 10. Time-course of PMA-induced internalization of the different α_{1D}-AR mutants. Panel A: Accumulation of intracellular fluorescence in response to PMA1 μM in cells expressing the ΔN, ΔN-MutIL3, ΔN-MutIL3-P.R. and ΔN-MutIL3-D.R. mutants. The intracellular fluorescence observed, under baseline conditions, in cells expressing each of the mutants was considered as 100%. Plotted are the means and vertical lines representing S.E.M. of 7 independent experiments in each of which 3–5 cells were analyzed (n = 20–35). Panel B: Representative images.

triggers an association with the scaffold protein, β-arrestin, favoring the action of the endocytic machinery, receptor internalization and putatively switching from G protein-mediated signaling to β-arrestin-mediated action [28–33]. Some of the present results indicate that not all GPCR phosphorylations trigger receptor internalization, but rather the opposite: these results were totally unexpected and extremely puzzling, but at the same time, are provocative and their interpretation is challenging.

Our data indicate that the phosphorylation state of residues T507, S515, S516, and S518, which are located in the distal cluster of the C-terminal tail, regulate the subcellular localization of α_{1D}-ARs. When these residues were exchanged for non-phosphorylatable amino acids, the α_{1D}-ARs were localized mainly in intracellular vesicles. This was contrary to our expectations; i. e., we anticipated that the absence of phosphorylation sites would favor receptor retention at the plasma membrane. The possibility that the amino acid substitutions could alter the receptor's conformation was considered, but substitution of these same residues for the phospho-mimetic amino acid, aspartic acid, restored the receptor's plasma membrane localization. This is completely counter to the general idea that all GPCR phosphorylations could be functionally translated into desensitization, internalization, and possible degradation, and that a general action of protein phosphatases might trigger receptor recycling. The present findings suggest that these processes are more complex than anticipated and that it is likely that phosphorylation at some specific sites could lead to internalization, whereas at others this might favor membrane localization. To the best of our knowledge, this is the first study indicating that the phosphorylation of certain residues in a GPCR CTail could favor receptor localization at the plasma membrane. However, it must be mentioned that it has been reported that prolonged inhibition of PKC induces down-regulation of sphingosine 1-phosphate $S1P_1$ receptor surface expression, associated to decreased receptor phosphorylation, but the mechanisms or residues involved were not explored [54]. Similarly, there is evidence that phosphorylation of channel receptor (also called "ionotropic receptors") subunits, such as those of AMPA/Glutamate receptors or $GABA_A$ receptors increase their membrane localization (see, for example [55–58]).

The steady state density of plasma membrane receptors results from a balance between several complex processes, i. e., anterograde transport and insertion into the plasma membrane, internalization and recycling. Intracellular accumulation of receptors might result from decreased plasma membrane insertion, by a reduced time of residence in this organelle due to increased internalization or improper recycling; these events are not mutually exclusive and combinations might exit in response to key structural modification. The absence of α_{1D}-AR phosphorylation sites, in the distal CTail cluster, could render membrane targeting/insertion more difficult or could impede it. Similarly, it is possible that even if membrane insertion takes place, the absence of this phosphorylated sites could reduce the time of residence of these receptors at the plasma membrane by increasing its internalization and/or reducing its recycling back to this organelle. All these possibilities, together with the intrinsic activity of α_{1D}-ARs, might explain why with

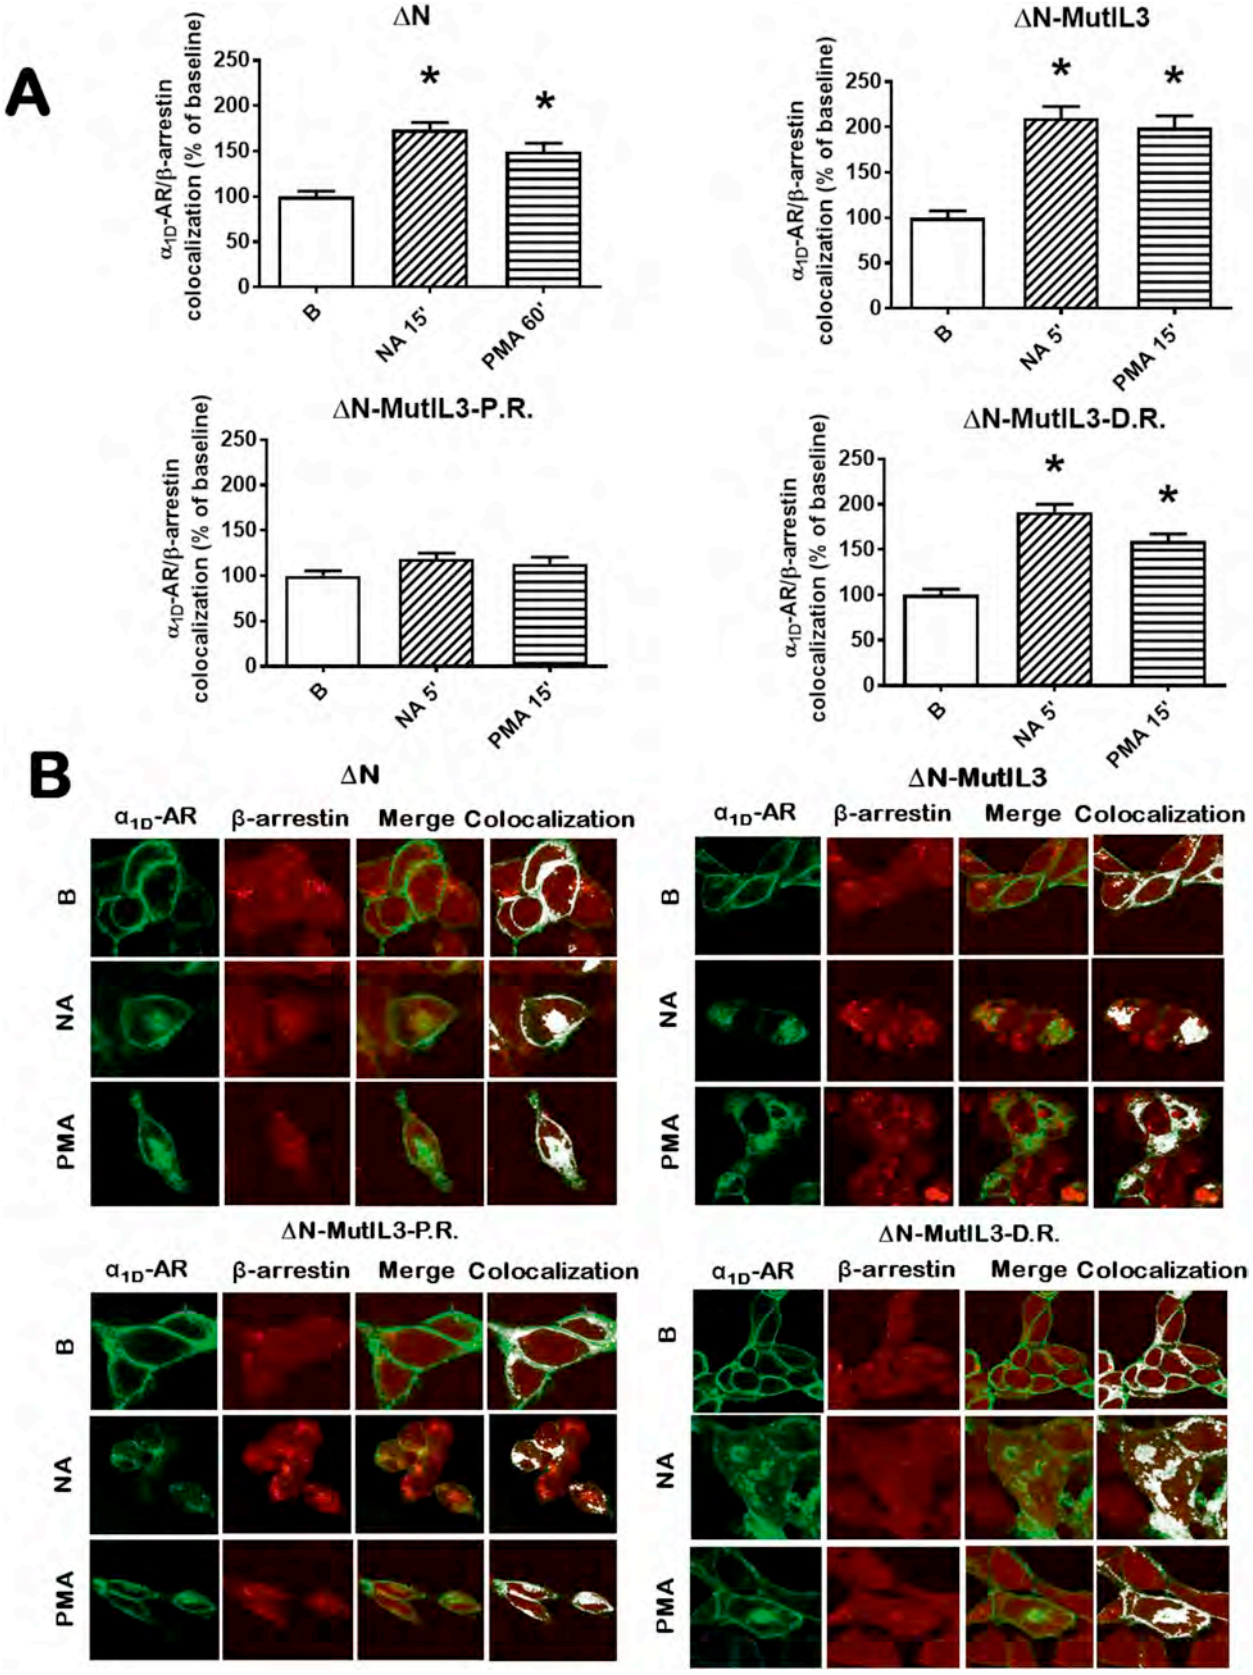

Fig. 11. Colocalization of the α_{1D}-AR mutants with endogenous β-arrestin 1/2. Panel A. Cells expressing the ΔN, ΔN-MutIL3, ΔN-MutIL3-P.R., and ΔN-MutIL3-D.R. mutants were treated without any agent (B, baseline) or stimulated with NA 10 μM or PMA 1 μM for the times at which each mutant showed a higher level of internalization (i. e., 5,. 15 or 30 min, as indicated in each histogram). Data were normalized considering the baseline colocalization observed, under baseline conditions, as 100%. Plotted are the means and vertical lines representing S.E.M. of 7 independent experiments in each of which 3–5 cells were analyzed (n = 20–35). * $P < 0.05$ vs. baseline (B). Panel B. Representative images are presented showing the α_{1D}-AR mutants (α_{1D}-AR, green channel), β-arrestins 1/2 (β-arrestins, red channel), merge images (merge) and colocalization (colocalization, white); treated as indicated; B, baseline, NA 10 μM or PMA 1 μM.

this receptor subtype, a relatively high degree of baseline phosphorylation was consistently observed [22–24,26,27]. In fact, S516 and S518 were detected as phosphorylated under baseline conditions in our work using mass spectrometry [22]. It is possible, therefore, to suggest that during receptor internalization and recycling processes, a series of different protein kinases and phosphatases could participate, forming functional elements of the signaling complexes, in a dynamic fashion.

Modification of the proximal cluster (T477, S486, and S492) with non-phosphorylatable amino acids also induces an important intracellular localization of these receptors, but substitution with aspartate did not favor their presence at the plasma membrane. This suggests that the proximal cluster might also play a role in receptor subcellular distribution but one of minor importance.

Interestingly, the ΔN-ΔC and ΔN-MutIL3-ΔC mutants exhibited a very high degree of internal localization as compared with the remainder of the mutants. This suggests the possibility that the CTail might exert a pivotal influence on the subcellular localization of this receptor. It is possible that, in addition to the detected phosphorylation sites, other undetected phosphorylation sites and/or structural elements in the CTail could have an impact on the expression of this GPCR at the plasma membrane.

The functional data obtained in this work are also worth considering. Previous information had shown that CTail truncation (i.e., the ΔNΔC mutants) did not decrease the ability of NA to increase intracellular calcium concentration [22,24], the latter being a G protein-triggered action. However, substitution of the phosphorylation sites with non-phosphorylatable amino acids leads the ΔN-MutIL3 receptor mutant to exhibit a partially decreased ability to increase intracellular calcium in response to NA; similar data were obtained for the ΔNΔC-MutIL3, as previously reported [22]. In addition, it was observed in this work that all of the different mutants of the CTail containing non-phosphorylatable amino acid substitutions exhibited a decreased calcium response to NA. In contrast, mutants with aspartate substitution in the clusters maintain the ability to increase intracellular calcium in response to the adrenergic agonist, either partially (ΔN-MutIL3-P. C. Asp mutant) or completely (ΔN-MutIL3-D. C. Asp and ΔN-MutIL3-T. M. Asp mutants). With these mutants there seems to exist a correlation between their ability to increase intracellular calcium in response to NA and their localization at the plasma membrane. In the case for the ΔNΔC mutant, there was a large accumulation of receptors in intracellular vesicles but nonetheless, a full calcium response was observed [22,24]; with the ΔNΔC-MutIL3 mutant NA-induced calcium response was smaller (confirmed in the present work, data not shown). It is likely, therefore, that membrane localization and an unmodified IL3 are critical for proper α_{1D}-AR-Gq interaction and consequent calcium signaling; however, we cannot discard the possibility that phosphorylatable residues or structural elements in the α_{1D}-AR CTail might participate in the interaction with Gq.

The ability of the different α_{1D}-AR receptor mutants to increase ERK 1/2 phosphorylation was studied. This is a signaling process that governs cell proliferation, differentiation and survival and it is modulated through many cellular pathways [32,59]. Not surprisingly, it was observed that both the expression of β-arrestin 1/2, and EGF receptor transactivation play roles in this action. We evaluated NA-activated ERK 1/2 phosphorylation in cells expressing the different receptors, and our results indicated that the kinetic profile of activation was very similar for all receptors containing the MutIL3 non-phosphorylatable mutation (i. e., a rapid and essentially sustained activation for up to 60 min) but different from what was observed with the ΔN receptor (i. e., a rapid activation that progressively decreased after 30 min); this is consistent with previous observations [22] and suggests the possibility that phosphorylation of IL3 plays a major role in turning off ERK 1/2 activation. Receptors containing the ΔN-MutIL3 mutation and non-phosphorylatable substitutions in the CTail markedly activated the ERK 1/2 pathway, but were defective in increasing intracellular calcium in response to NA, i.e., they behaved as biased receptors.

It has been observed that phosphorylation of a given GPCR can take place at different sites, depending on cell type and other conditions, and that this is associated with different functional outcomes. The possibility that such an association could be causally related has been suggested and has been denominated the bar-code hypothesis [60–62]. Efforts to characterize phosphorylation sites of different GPCRs and their functional significance have been reported (see, for example, [22,39,63–69]). The data presented here, supports the phosphorylation bar-code concept and indicates a new role for GPCR phosphorylation (i. e., one favoring membrane localization). If this is unique feature of α_{1D}-ARs or can be generalized for other GPCRs remains to be determined.

5. Conclusions

Our present results suggests that phosphorylation of a CTail distal cluster (T507, S515, S516 and S518) favors α_{1D}-AR localization at the plasma membrane, i. e., substitution of these residues for non-phosphorylatable amino acids results in the intracellular accumulation of the receptors, whereas phospho-mimetic substitution allows plasma membrane localization. Substitution of IL3 phosphorylation sites for non-phosphorylatable amino acids resulted in agonist-induced sustained ERK1/2 activation, which was not altered by additional mutations in the phosphorylated residues in the CTail. In contrast, mobilization of intracellular calcium appears to be controlled by IL3 and CTail phosphorylation states. IL3 mutation affects, differentially, NA- and PMA-induced receptor internalization and substitution of the CTail phosphorylation sites seems also to participate in this process.
